*Upper Canada.*—From the Reports for the past year of the resident agents on the free grant Road in Canada West, and which will be found in the Appendix, Nos. 1, 2, 3, 4, 5 and 6, the progress on these roads will be considered most encouraging and satisfactory. The number of families settled on these roads, the value of the season's produce, and the number of acres cleared, increase steadily year by year, and afford a true index of the prosperity of the settlements.

The annual Reports of Mr. Gibson, chief superintendent of roads for Canada West, and of Mr. Snow, superintendent of the Mississippi Road, with the usual approximate statements of the work done on the Roads in Canada West up to 31st December, 1861, and a statement of the total number of miles open to the same date accompany this report. (Vide Appendix No. 8.)

*Lower Canada.*—The management of the Lower Canada Colonization Roads has hitherto been undertaken by the Department of Crown Lands. Arrangements have, however, since the beginning of the month, been made, to transfer

the supervision to this Department, which will for the future receive the reports from the resident agents, collect statistics, and control the management of the Lower Canada Roads, in a manner precisely similar to that heretofore adopted in respect to the Roads in Upper Canada. In future, therefore, the Department will be in a position to give details on the important subject of Lower Canada Colonization, which it finds itself at the present moment unable to furnish. From the Returns of the Department of Crown Lands, it seems that there are in Lower Canada 91 Colonization Roads extending over the whole of the Lower Province, on both sides of the St. Lawrence, and on the northerly bank of the River Ottawa, from Gaspe to Pontiac.—During the past year 107½ miles have been completed, 79½ miles opened, 13½ miles repaired, and eleven large bridges built, involving altogether an expenditure of \$52,683 06.

In the Report of the late Mr. Boutillier, for the year 1860, the total number of miles opened in these roads is stated to be 1,458. It would appear therefore that at the close of last year the total number of miles opened was 1,537½.

Detailed information respecting the Elgin and the Matane and Cap Chat Road, may be found in the reports of the resident agents attached to the report of the Commissioner of Crown Lands.

#### AGRICULTURE.

The circulation of the customary queries relating to the Agricultural interests and prospects of the Province has been resumed this year, but the replies which have been made are neither in number nor in the information which they convey, so satisfactory as could be desired. Notwithstanding that upwards of 800 circulars were issued in December last to the County Agricultural Societies, the Wardens, Reeves, and other influential persons in Upper Canada, and 500 to the Agricultural Societies, Municipal authorities, and others, in Lower Canada, not more than 45 to 50 returns have as yet been received from either section of the Province. This apathy and indifference to the efforts of the Bureau are most discouraging, and entirely preclude the possibility of arriving, at the present time, at any just conclusion as to the result of agricultural labours during the past year, or of the agricultural progress the country is making.

This report has been delayed in the hope that an abstract of the agricultural statistics for Canada, obtained by the Department from the census returns for 1861, would be attached. Though the most strenuous exertions have been made, it has been found impossible to include it without delaying the Report longer than is considered desirable. The agricultural returns for the whole Province will be ready in a few weeks, and will be immediately published.

The cultivation of flax has lately received much attention at the hands of the Government.

This branch of Agriculture has hitherto been much neglected, notwithstanding that the soil and climate of Canada seem admirably adapted to its success. In order to promote the more extensive production of flax, and with the view of affording the fullest instruction and information as to the mode of scutching and dressing it, the Government has lately imported six of "Rowan's new patent flax scutching machines," to be distributed over both sections of the Province, subject to the order of the Department.

The undersigned has decided that these machines shall be distributed under the advice of the Agricultural Boards, and it is proposed that they shall be moved from place to place throughout the country, and thus extend their usefulness over as wide a district as possible. The absence of proper dressing mills appears to have, hitherto, prevented Canadian farmers from cultivating flax to any large extent, for though, as Mr. Donaldson (to whose representations and exertions in the matter this Department stands much indebted) states, there are some very good mills in the country, such as that of Mr. McCrea, at Canestoga, in the County of Waterloo, that of Messrs. Blaikie & Alexander, at Norval, and others, yet in the replies to the agricultural queries to this Department, almost universal complaint is made that no facilities exist for dressing and preparing any flax which may be grown.

#### CENSUS OF 1861.

Considerable progress has been made in tabulating and preparing for publication the statistics collected by the Census returns last year. Already have the detailed statistics relating to origins and religions of both sections of the Province been published and distributed in a pamphlet form among the members of the Houses of the Legislature. The agricultural portion of the Census is nearly completed, and is being rapidly prepared for the printers. Every effort is being made by the Department to bring the whole work to a conclusion at the earliest possible date.

#### BOARD OF ARTS AND MANUFACTURES.

The annual Report of this Board as prescribed by the 28th sec., 10 Vic., cap. 32, has been received.

The general condition of the society appears to be satisfactory, but the withdrawal of all Government aid from the Mechanics' Institutes appears to have resulted in the failure of some of them, and in crippling, materially, the usefulness of others. Some few of them, however, in cities and towns are not only self supporting but prosperous.

The statements of the treasurer of the Board show a balance in hand after payment of all expenses of \$1,923 63. The valuable works belonging to the Patent Office, left under the charge of the Board of Arts and Manufactures, are highly appreciated, and several donations of

Tessellated pavements with other and interesting specimens of manufactures are acknowledged. The library is entirely free for consultation, and is said to be more readily accessible than any other free library in the Province.

#### IMPROVEMENT FUND.

The "Improvement Fund" for 1859, accruing to the several Municipalities in Upper Canada, to be expended in Roads and Bridges is now in course of distribution.

#### PATENT OFFICE.

The business of the Patent Office is steadily increasing. During the past year, the fees received for Patents of Invention amounting to \$3,020 00, those for assignments, copies of specifications, and registration of Trade Marks to \$194 30, amounting together to the sum of \$3,214 00, which has been paid to the credit of the Honorable the Receiver General. This department of the Bureau has now become self-supporting.

The Royal Patent Commissioners in London, continue to present to the Bureau the specifications and engravings of patents issued in the United Kingdom. They now amount to 500 volumes.

Since the removal of the Government to Quebec, 443 models have been received by the Patent Office.

It is much to be regretted that want of accommodation has hitherto deprived the public in a great measure of the advantages which they would otherwise derive from the museum of models and valuable library of books. The models should be classified, numbered, arranged, and a descriptive catalogue should be prepared. The room might then be open to the public, say daily during the session of Parliament, and perhaps twice or thrice a week during the remainder of the year.

In conclusion the undersigned alludes with the deepest regret to the loss which this department has sustained in the decease, during the past year, of Mr. W. Hutton, for many years the active Secretary of the Bureau.

The whole humbly submitted.

N. F. BELLEAU,

*Minister of Agriculture.*

Bureau of Agriculture, Emigration, }  
and Statistics, Quebec. April 1862. }

#### The Preparation of Food for Cattle.

The directors of the Royal Agricultural Society of England have recently introduced the practice at their monthly meetings of discussing agricultural subjects. In the *Irish Farmer's Gazette* of the 17th ultimo, we find the following condensed report on the interesting and im-

portant subject of "preparing, mixing, and cooking of food for cattle." Mr. Frere, the editor of the society's journal, introduced it to the meeting, and based his observations on Professor Voelcker's paper on the composition and nutritive value of straw, which appeared in the last part of the Society's Journal; on Mr. Lawes' reports of his experiments conducted on the Duke of Bedford's estate; and, finally, on "his own small experience in cattle feeding last autumn." Mr. Lawes stated, however, that the results of the experiments which he had made, and to which Mr. Frere alluded, could not be taken as a standard in so far as related to the comparative merits of cooked and dry food, having been conducted for another purpose altogether—namely to ascertain the amount and composition of the dung of cattle, and more particularly with reference to the loss of ammonia. We may, therefore, set aside those of Mr. Frere's remarks which were based on Mr. Lawes' report, as being inapplicable to the subject under consideration, and pass on to some of his subsequent observations.

He alluded to the practice of giving cattle first a bait of meal, then a bait of turnips, and so on; varying the food at different parts of the day, informing the meeting that the most experienced feeders he had met with considered it best to mix roots, cake, and meal, giving the same mixture at each feeding time. Referring to his own experience in cattle feeding last year, he stated that he had been

"Anxious to try the effect of cooking in the case of 10 beasts, 2lbs of bean-meal boiled and poured over the chaff was to stand for 24 hours; 2lbs of cake were then added to this mixture, and it was served up next day. Of these 10 beasts one obstinately refused to eat the mixture. It was a white bull with a black nose, and was decided the worst beast of the lot. So stontly did it reject the mixture that it would eat the straw turned out from the cart horses, rather than this prepared food. It was then ordered to have bean-meal unboiled, the meal being still mixed with straw, which was moistened the day before, and a small quantity of malt combs, which was also moistened on the previous day. At this moment that which was the worst beast of the 10 was indubitably far the best: it weighed over 8 stones more than those which were of the same size when they came in, and 1 cwt. more in live weight than the smaller animals did when they came in. In short, it weighed 56lbs. more than any of the other beasts in the lot. He mentioned this case to Professor Voelcker, who, in his reply, said:—The incident you mention with respect to your black-nosed bullock is curious. I don't like to boil pea-meal, or to pour it afterwards over roots and chaff. Substances so rich in nitrogenized matters as peas and bean meal are very apt to give rise to putrefaction, instead of

lactic acid fermentation. For the same season, it won't do to mix much cake mucilage with other food, and to let it be a long time. If soon consumed after the addition of the cake jelly, no harm is done; but if left too long after the addition, incipient putrefaction and mould, both of which are highly injurious to the preparation of cattle food, become perceptible in the mess. The more nitrogenous matter in the material employed, the greater its tendency to putrefy. When malt combs are soaked in water and then mixed with chaff, lactic acid is readily formed if there is sufficient water present and the temperature is sufficiently high. Sugar, in the presence of much water and a sufficient quantity of albuminous matter, becomes changed into lactic acid—an acid which has the same per-centic composition as milk sugar itself. Too much or too little albuminous matter is alike unfavourable to the production of lactic acid."

Mr. Frere stated that he gave each of these animals every day "1lb. of malt combs, 3lbs of linseed, 2lbs. of cotton cake, 3lbs of bean meal, 2lbs. of carob or locust bean, 2lbs. of mangel wurzel, and 8lbs of straw." His impression was that there were more economical modes of preparing food for cattle than by boiling.

Mr. Lawes did not think there was any saving effected by cooking food for cattle, if the increased labour and cost of fuel were taken into consideration; nor did he believe that although the use of cooked food might produce a greater quantity of meat than dry food, that the increase of meat produced by the former mode was as valuable as that which was produced by the latter, although less, perhaps, in quantity. Meat produced by the use of cooked food was not satisfactory to the consumer, as it "boiled away," because all animals as they fatten have a certain amount of water displaced; that is to say, they contain less and less water as they approach "ripeness" when fed on uncooked food; but the water in the flesh increases, as well as the fat, instead of being diminished, when the food given is cooked, and he illustrates this by the following statement:—

"Some time ago he fed one animal on steeped barley and another on dry barley, with a view of treating the merits of the two systems of feeding. The animal which was fed on the steeped barley increased very fast, while the increase in the case of the one fed on dry barley was comparatively slow. They were both killed; the loins and other parts were cooked on the establishment, and it turned out that there was much more waste in the former than in the latter."

Notwithstanding his own opinions as to the relative value of meat produced by cooked and uncooked food, Mr. Lawes considered that sufficient facts were still wanting to enable any one to speak confidently on the subject; but, on the whole, he thought that cooking was only advisable when food was exceedingly scarce.

Mr. Dent spoke in favor of pulping, having known many gentlemen who had given up the use of cooked food, but none who had abandoned pulping after having once tried it. He was anxious to learn, however, whether the pulped food should be given fresh or in a state of fermentation; also as regarded store beasts, the best proportions of roots and chaff; and whether it was most advantageous to mix dry food or oil-cake with roots and chaff, or to give them separately. He further stated that he had found the use of malt combs profitable in the case of milch cows, as the yield of milk fell off whenever the supply of malt combs ceased, and improved when this description of food was again given to the cattle. Mr. Dent's enquiry as to the propriety of giving the pulped roots in a fresh or fermented state is one of much practical interest, and Mr. Lawes' reply on this point was as follows:—

"It must be borne in mind that all fermentation was the combustion of that which was the most valuable of all the elements of food, namely carbon. An animal would eat till he had got sufficient carbon in his stomach, and then stop. Carbon was the measure of his feeding powers; he stopped eating when he had enough soluble carbon. That was the first substance that would disappear during fermentation; and therefore, he did not think it likely that there was any economy as regarded food in a process of that kind."

Mr. Lawes was, therefore, in favour of giving the pulped food in a fresh state, as

"There was a great risk of fermentation proceeding too far, and he thought many persons had given up the practice of mixing and pulping food, and keeping it in heaps, from the very fact that fermentation went on too rapidly.—Even if it did not putrefy, they lost the most valuable elements of the food."

Mr. Frere having asked for information "as to the influence of food in which incipient fermentation was commencing upon the work of digestion," Professor Simonds referred to this point in the first place, when pointing out the physiological view of the question, which he did in the following manner:

"As regarded the question as to whether the commencement of putrefactive fermentation was likely to interfere with the process of digestion, it was well known that the food of carnivorous animals was consumed chiefly when in a state of putrefaction; but the antiseptic powers of gastric juice were so strong that it was rendered sweet at once. The gastric juice of carnivorous and herbivorous animals did not differ, so that the same action would take place with reference to the consumption of food in which putrefactive fermentation had taken place. He did not, consequently, consider it likely to interfere with the digestive powers of the animal. His opinion with reference to all these matters was that they dealt too much with chemistry, and not

sufficiently with physiology. Mr. Lawes had truly stated that the question was, commercially speaking, whether giving cooked food would in reality pay. They ought not to be surprised to find that cooked foods were not so well calculated to build up the animal and obtain a good quality of flesh. It had been shown that it, technically speaking, boiled away; and the reason given, no doubt, was the just one, that if food was given containing a large quantity of water, more water was absorbed in the organization of the animal than if dry food were given. Speaking as a pathologist, he believed that a great number of the diseases of the lower animals were to be traced to the bad quality of blood, arising from an excess of water and a deficiency of nitrogenised food. The practical farmer knew very well that in the lambing season if the ewes eat too much wet turnips or wet tops a bad quality of blood was produced, and the ewes would become diseased and die unless a large quantity of dry nitrogenised food were given. There was another question with reference to cooked food. Admitting for a moment that it was an advantage to the animal, and that it accumulates a large quantity of flesh in a short space of time, and that they regarded that, for argument sake, as so much gain, he was inclined to think that it arose from the facility it gave for the digestion of the food by anticipating a part of the process which it underwent from the action of the gastric juice.—For a simple-stomached animal like the horse, they knew very well that the food would be at once converted into a fibrous mass; a chemical change took place, and that pulpy material on passing into the intestinal canal became mixed with various secretions, including bile; another chemical change took place, and the chyme was separated from the chyle, and the latter being the nutritious portion of the food, was absorbed into the blood. The question was, whether in giving an animal, and especially a ruminant animal, cooked food, they did not to a considerable extent supersede mastication; if so, they would supersede insalivation, and thus interfere with one of the first processes of nature, and do harm. What was the action of the saliva on the food? Without going into the intricacies of the question, they had the amylaceous parts of the food first converted into sugar or gummy matter, which was a soluble material chemically allied to sugar, and, as has been stated, it was only after a sufficient quantity of carbon had been obtained that an animal ceased to feed. A provision was made in the ruminant animal for stirring up, if he might so express it, the food; and a chemical change took place in its character before it passed into the true digestive stomach. There was a re-mastication and a re-insalivation; and, inasmuch as the secretions coming from the rumen were very analogous to those with which the food was mixed in the mouth, it remained not only mixed

with saliva a much longer time, but was mixed with a much greater quantity of saliva. If, then, by the use of cooked food they dispensed with part of the operations of nature and sent the food quicker into the intestinal canal, they would dispense with the process of re-mastication and re-insalivation; and he could easily understand why, although a large increase might take place in bulk, the quality of the animal might become bad. For the same reason it was objectionable to pulp food too fine, but they might with advantage soften chaff that was four or five inches long, so as to commence the process of converting the amylaceous part of the food into sugar without interfering with the functions of the rumen. There was no doubt in the world that they could induce animals to eat a larger quantity of food by imparting a relish to it, which they could do by throwing a small quantity of cooked oil-cake over it; but, on the whole he was not in favor of the so-called cooking of food either as a means for the preservation of the health of animals or of promoting the process of digestion. He was inclined to think, physiologically speaking, that by pulping food, cutting straw, and mixing it with a solution of oil-cake, they would gain their point at a much lower expense, and in a much better manner for the animal economy."

The discussion closed with Professor Simonds' valuable remarks; and we need scarcely remind our readers that the question of cooked food is one which has been frequently agitated, and which still remains, as Mr. Lawes' observations show, in a somewhat uncertain state. That cattle will not pay if fed solely on cooked food, although they fatten more quickly than those fed entirely on raw food, has been long known to experienced feeders; but it has also been shown that a portion of the food may be cooked with advantage. This has been proved by several cases, the details of which have been laid before the public: at the same time, it is likely that pulping will, as a general rule, supersede cooking, being less troublesome and less expensive, especially when the pulping machine is driven by steam or water power.

### Liquid Manure Farming at Myre-Mill, Scotland.

The glory of Myre-Mill has departed. The engine for the most part stands idle on the hill; the wooden coverings of the mouths of the monster tanks are broken or rotting, and the manurial contents are hardly thought worth the expense of distribution.

Of course, everybody interested in farming pursuits has heard of Myre-Mill, where liquid manure farming was long supposed to be carried on to the greatest perfection and profit. It was first brought prominently before the public in the "Minutes of Information" re-

garding sewage manures, issued by the General Board of Health. From this account one would have supposed that the proprietor, who himself carried on the farm, under the immediate superintendence of a practical farmer, was about to realise a speedy fortune from his enterprise. We were told that "one field of ray-grass, sown in April, had been cut once, fed off twice with sheep, and was ready (August 20) to be fed off again." In another field, that had yielded within the year four cuttings of the estimated weight of nine or ten tons per acre, the aftermath was valued at £250 per acre, for sheep-feeding purposes. Swedes which had received a supply of liquid manure were ten or twelve days earlier than another lot that had got double the quantity of solid manure without the liquid application, and were better than those in a neighbour's field to which dozens of loads of farm-yard manure had been applied, in addition to 3 cwt. of guano and 16 bush. of bones per acre. Carrots and cabbages were equally susceptible to the fertilizing influence of the liquid manure; and Italian ray-grass sprung up on its application almost like the grass in that remarkable district "down east," where, though it were cropped close at night, you were lost in it by the morning, and where, if you planted carpet-tacks in the evening, they would be tenpenny nails by sunrise. And then the effect of this liquid manuring was by no means evanescent. "There is not the slightest appearance of exhaustion in the land; its fertility appears to increase. I was informed that, before the liquid manure was used, the land would not keep more than a bullock or five sheep to the acre; now it will maintain, if the crops are cut and carried in, five bullocks or twenty sheep to the acre." Somehow or other, the money returns were by no means such as these rapturous accounts of fertility implied. Those magnificent crops, instead of being a source of profit, were singularly the reverse, and the proprietor's banking account, so far as it concerned Myre-Mill, grew smaller and smaller every year under the frequent cuttings and tremendous weights of Italian ray-grass. The reason was simple—the cost of production was a question never taken into consideration under this system of very high farming. When it did compel attention some five years ago, Mr. Kennedy deemed it advisable to surrender his farm into the hands of a tenant farmer, who of necessity was bound to count the cost, and the calculation was far from favourable to the practice so extensively and vigorously pursued by his landlord.

Being in Ayreshire the other day, we paid a visit to Myre-Mill, which is situated about a mile from Maybole, a short distance from the public road between that place and Ayr. The steading occupies a considerable elevation, nearly in the centre of the farm, and

possesses an unusual amount of accommodation for a farm of between 300 and 400 acres. It is very easy to see that Myre-Mill was built under the influence of much more liberal ideas than such as dictate the erection of farm-steadings for tenant-farmers—that it had been a proprietor's pet place. The byres, barn, granary, stables, store-houses, &c., are on a scale of sufficient magnificence for a farm of double the superficies. But doubtless it was expected that the liquid application would more than double the produce raised by the common method of manuring. The tanks for the reception of the liquid manure from the byres, stables, &c., occupy a great square in front of the root house, from which the ground was excavated, the sides being then solidly built round with stone, after which the hollow space was divided into four unequal compartments by substantial walls. The tanks thus formed measure respectively in feet:—48 × 14 × 12; 48 × 14 × 15; 72 × 14 × 12; 72 × 17 × 12. They are numbered 1, 2, 3, 4, and each has a separate communication with the well, from which the contents are pumped up. A twelve-horse engine works the pumps, and it is stated that about 4,000 gallons, which is the quantity usually allowed for an acre, can be distributed in an hour. Iron pipes, with hydrants at convenient spots, are laid over the whole of the farm, and with the hose the extent of delivery amounts to about 1,900,000 yards. The cost of this machinery was £1,586, divided as follows:—Tanks, £300; steam engine £150; pumps, £80; iron pipes, laying, and hydrants, £1,000; gutta-percha and distributing pipes, £56. One great draw-back is the want of water to mix with the manurial flowings from the courts. This has to be raised a height of 70 feet from a burn flowing through the hollow in front of the steading.

On the day of our visit, however, the tanks were choke full, and water from the steading was allowed to trickle away down the hedge-side into the burn, from which the supply was usually to be derived.

The present tenant, Mr. Duncan, has little faith in the virtue of the application. At all events he does not think that it is worth much more than the cost of its distribution. In washing in guano or other manurial substances into the roots of the plants in dry weather, he believes to be valuable; but in ordinary cases he is of opinion that the money expended in applying it would be as profitably laid out in the purchase and application of solid artificial manures. In order to test the correctness of this notion, Mr. Duncan, when urged upon by the proprietor—who is still a strong believer in liquid manuring, notwithstanding the losses he sustained thereby—to distribute the tank-liquid on one of the out fields, offered, if the landlord would be

at the cost of applying the liquid to a portion of the field, to raise a better crop on the other portion with solid manure at a like expense per acre. The proprietor, however, declined the challenge.

It might be supposed from what we have said that Mr. Duncan was an out-and-out opponent of the system. This is not the case, however, he entered the farm with the belief that its value was enhanced £1 per acre by the tanks, pumps, and piping, but his opinion now is, that these are not worth a fifth or sixth of that sum.

In reply to our enquiries as to whether the application did not permanently benefit the soil—whether the field from which the immense crops of Italian ray-grass had been raised did not develop in a corresponding degree, the other crops in rotation, Mr. Duncan stated that he thought more was due to the heavy manuring than the watering with liquid from the tanks.

We are not disposed to think so lightly of the value of liquid manure as Mr. Duncan appears to do. Undoubtedly great results have been obtained from its application, but it is equally certain that its value has been by some very much over-rated; and we are doubtful whether it can be shown to be profitable where great and costly works have to be erected for its collection and distribution. But where farms are so situated that the liquid can be distributed over the fields by gravitation, there can be no question as to the benefits to be derived from its use, and it would be gross waste in such circumstances to allow it to flow away into a ditch or a burr, to stimulate the weeds in the one, and poison the trouts in the other.—*Scottish Farmer.*

### Pig Breeding and Feeding.

A few days since a lecture on the breeding and feeding of pigs was delivered to the members of the Worcestershire Agricultural Society, by Mr. Baldwin, of Bredon House, near Birmingham.

In opening the lecture, Mr. Baldwin said—In 1845 he entered on a farm at Kingsnorton. In 1846 he purchased two gilts and a boar, of the Tamworth breed, from his cousin, Mr. T. Baldwin, of Barnt-green, who was famed for his breeds of Tamworths; and although he (the lecturer) commenced breeding with three pigs in 1846, in 1851 he sold £1,000 worth of store and fat pigs within one year; and in the years 1852, 1853, 1854, and 1855 he sold £1,000 worth each year. The idea of feeding such numbers of pigs was first conceived by him at a county meeting at Worcester, in 1849, after free trade had come

into operation. The meeting was called to take into consideration the state of agriculture, and to petition government to pass another act for its protection. At that meeting he (Mr. Baldwin), believing it impossible to return to protection, moved an amendment to the effect that, as the tax upon malt was a burden upon the British farmer, it should be repealed. Mr. Curtler was the principal speaker in favour of protection, and, during his address, produced many samples of foreign produce at amazingly low prices. Among them was a good sample of Egyptian beans at 9s or 9s. 6d. per bag; Indian corn at the same price, and Dantzic wheat also very low. Mr. Curtler then exclaimed, "Gentlemen, can you grow them at these prices?" He (Mr. Baldwin) being a consistent free-trader, looked on the bright side of the question, and began to ask himself how he might turn the low price of corn to good account. It struck him that as he had a great many store pigs, he would feed them, instead of selling them as stores. He accordingly bought a large quantity of Indian corn at from 9s. to 9s. 6d. per bag, to begin with; and within two years and a quarter from that time he bred, fed and sold £2,000 worth of pigs, and cleared, after paying all expenses, £500, besides making a vast amount of manure, which he considered far better than guano, because more durable. During the greater part of these two years and a quarter, Indian corn, Egyptian beans, and feeding barley ranged from 9s. to 12s. 6d per bag of ten score, and he sold his fat pigs at from 7s. 6d. to 8s. 9d. per score. The plan which he adopted in breeding was to put the sows to the boar in November, and pick the breeders principally from the earliest pigs. When he had got his stock up to about 40 breeding sows, in picking the breeders he used to pick them several times over, as it frequently happened that those which looked the prettiest and best when young altered considerably when they got three, four, or five months old. The rule was to pick long-growing pigs, and those that were straight and thick through the shoulder and heart; and experience had convinced him that his method of choosing was a correct one. There need be no greater proof of that than the number of medals and prizes he had obtained. He always kept to the Tamworth breeds, generally purchasing the boars, but breeding the sows. If he found the pigs getting too fine, he purchased a good strong boar, and if the animal exhibited tendencies the other way he picked a boar of good small bone, but was always particular to pick a boar that was thick through the shoulder and heart, and a straight-growing pig of the same colour and breed. By carefully following this plan he got the breed so good that it was a rare

occurrence to see even a middling pig in the flock, though he bred from 250 to 300 each year. His plan of keeping was as follows:—As soon as the sows littered they were kept on kibbled oats, scalded, with raw swedes or cabbage; and when the pigs got to the age of three weeks or a month, he turned the sows out from them for a short time every day, and gave the pigs a few peas or a little Indian corn while the sow was away. When the weather was fine and warm the pigs went out with the mother into a grassy field for a short time. He found that young pigs, from the age of three weeks, required dirt or grit, and therefore, if the weather was bad, and they could not be turned out, it was necessary to put some grit into the sty. This was very important, as he believed it was quite necessary for the proper digestion of their food. He had had young pigs looking very bad and drooping, but when turned out, that they might get dirt, they soon became all right again. In fact, it was absolutely necessary, during the whole life of a pig, to allow it an opportunity of getting grit or dirt, or it would not thrive well. At seven or eight weeks old all the pigs he did not require for breeding he had cut, and began to wean them a fortnight afterwards. He then turned them out into a grass field, with a hovel for them to run into, and allowed each pig a quart per day of peas, Egyptian beans, or Indian corn. English beans did not answer for young pigs, being too heating. He gave them one pint of corn in the morning, and the other in the evening, with regularity as to time and quantity, and found it better to give to them on the grass, in a clean place each time, than in a trough, as it prevented quarrelling, and each pig got his share. With this quart of corn per day, and what grass they got during the seven months of the year, with nothing but water to drink, the pigs would, on an average, make 5 lbs. of pork each per week. After eight months, he allowed an extra half-pint of corn per day. At the present price of corn the allowance would cost about 1s. per week for each pig; grass, 2d.; attention of man, 1d.; total cost, 1s. 3., leaving a profit of 1s. per week on each pig when pork was at 6d. per lb.; it was now 7d. One man attended well to from 200 to 250 pigs; he was an Irishman, for few Englishmen liked the job sufficiently well to take an interest in the pigs, and carelessness on the part of the man materially decreased the profit. He kept the store sows when in pig the same as the other stores. They ran about in a field till a fortnight before pigging, when he placed them in a covered shed, so constructed as to admit as much sun as possible. Young pigs kept in the manner described were always nearly fat enough for porkers, and did not require

more than two or three weeks feeding on meal. It was time enough to begin to feed pigs for bacon at 8 or 10 months old. Good breeding sows he allowed to have two farrows, and sometimes three, but never more, and then feed them for bacon, supplying their places with young sows. In selling store pigs he charged a certain price per lb., allowed the purchaser to pick the pigs from the field, which plan always gave satisfaction, and secured a return of custom. It was desirable in breeding animals to have as little bone as possible in proportion to flesh. He had tested a cut sow of his breed, about 30 months old, which weighed 32 score, and the whole of the bones, after the flesh had been boiled from them, only weighed 21 lbs.: so that for every pound of bone there were 32 lbs. of meat, which he believed to be a fair average of his breed. His pigs made 2 lbs. of flesh for every 4 lbs. of good Indian corn, barley, or peameal; as a rule, he preferred the Indian corn. He considered it always to be more profitable to feed upon good food than upon inferior. As a rule, pigs would thrive better for being turned out once a day, except in wet weather, and they would also be healthier, more active, have a cleaner appearance, would possess a great advantage in the show-yard over heavy, ungainly pigs, which could not move about to show themselves. One of the greatest pleasures which his breeding afforded him was to see the number of labouring men who came to buy from him, and he hoped to see the time when every labouring man would have a good pig in his sty.

### III Effects of Bad Corn.

A very curious and important paper appeared in the *Veterinarian* for February, 1862, which is highly worthy the attention of our readers, not only as a record of some very interesting facts, but as holding out a serious warning against the false economy of using bad corn as food. Mr. Mitchell, of Leeds, the gentleman who first called attention to the matter, has kindly promised to supply us with specimens of the corn in question, but in consequence of severe illness he has not at present been able to fulfil his promise. As the subject of such immediate interest, however, we have determined to reserve for future remark anything that may be presented by the specimens on their arrival, and to present the facts as they are presented to us in Professor Varnell's paper.

In a letter dated August 27, 1861, Mr. Mitchell states that a gentleman in his neighbourhood had lost six horses in a very sudden manner. A *post mortem* examination convinced some of the most eminent veterinary surgeons in the surrounding district that their death was due to poison; but an analysis of the intestines or their contents, as well as of the food which they had eaten, failed to show the presence of

any mineral poison, or of any appreciable deleterious organic substance. Three feeds, however, of the oats which formed the principal part of their food were administered to a horse by way of experiment, and death rapidly ensued.

At the same time, an old though healthy mare was purchased and placed in the same box, but fed on food obtained from a different source, and after a week, as she was still in good health, she was removed. A second experiment, however, was made with a pony, which was placed in a stable, at several hundred yards distance, and after three feeds with the suspected oats he was found dead, having eaten only a part of the third feed.

It was pretty clear, therefore, that the oats were the cause of mischief, but whether the evil proceeded from the oats themselves, or from any vegetable poison mixed with the oats, was doubtful. It was determined, therefore, to consult the best authorities in London, and an ample supply of the oats was forwarded for the sake of experiment as well as of analysis.

Accordingly, on the 10th September, 1861, a brown mare was procured by the college for the purpose of testing the oats. She did not fail quite so soon as in the two preceding experiments, but on the third day her hinder extremities became partially paralysed, and on the fifth she died. The oats were again analysed in London, and showed no traces of any known mineral or vegetable poison; but from the whole history of the case it seemed certain that the evil, whatever it was, was intimately connected with the oats themselves.

On a closer examination of the corn, apart from any chemical investigation, it was observed first, that it was musty and of a bad quality. It is not stated whether it was the produce of the previous rainy season, but in all probability such was the case. Many of the grains were then found to be matted together in lumps by a thready, cobweb-like substance.\* The greater part were covered with a black smutty matter, and the grain decomposed, the fecula being replaced by a blackish gray substance, which often projected beyond the surface. On examination this was found to consist of one or more species of mould. The examiner referred what he saw to the genus *Aspergillus*, but it is clear from the figures that there was certainly some species of *Ascochyra* as well, and probably the common *Penicillium* was also present.

Without the opportunity of personal examination, we are unable to say whether any spe-

cies of *Ustilago* had a part in the matter, but it is not probable that this was the case, as the spores of the *Ustilago* of the oat are easily blown away by the wind. The effects therefore produced by *Ustilago hypodytes*, as reported by Mr. Edwin Sidney, or of the large *Ustilago* of the reed, whose evil properties were first made known by Mr. Marshall of Ely, are not so much to the point as those which relate to the occasional effects produced by mouldy provisions strongly resembling those which presented themselves in the cases before us.

Professor Barnett, in his "Outlines of Botany," gives an account of the supposed deleterious effects of bread and animal provision when extensively covered with mould. A substance called Italian cheese, made of fragments of pork, strongly seasoned and converted into a sort of pie, is much used in some parts of the continent. This substance when mouldy has in many cases proved fatal. Dr. Paulus, of Saltz, records three deaths out of seven persons who were attacked with dangerous symptoms after partaking of such food; and many other cases are reported by other observers.

Mouldy bread and flour are also sometimes productive of similar evil. A case occurred at Hammersmith, about 1831, in which a family suffered from the use of some bread which was covered with a yellow mould. The bread, however, was itself of bad quality, the mould having appeared the very day the bread was baked. On analysis no poison was found, but the same bread when administered to a cat and dog was equally deleterious.

A question, however, arose whether the poison was in the food itself, or in the mould. Five grains of the mould, carefully separated from the bread, therefore, were administered and produced no bad effect, though a small piece of the bread from which the mould had been scraped produced colicky pains and a tendency to diarrhoea. To test the matter more closely, a quantity of dough was allowed to become mouldy in a damp place, and when the mould was carefully removed, it was made into a small loaf and baked, and the loaf thus formed had precisely the same poisonous properties as the Hammersmith bread, while the mould itself was eaten by a cat and dog with perfect impunity.

The subject attracted great notice in Paris some years ago, from the barrack bread becoming covered with a bright red mould almost as soon as was baked, due to the species of *Penicillium*, *P. sitophilum*, but we are not aware that it led to any positive results as to the deleterious effects of the fungus.\*

\* Wheat of 1860, which was in general in a very bad condition, exhibited frequently a curious appearance when stored up in large quantities. If the surface wheat was removed gently, the subjacent grain was found to form more or less solid pyramids of different heights, which were found on examination to arise from the grains being bound together by threads spun by a little mite. The wheat from these pyramids was extremely clammy when handled, and had a peculiar smell. In this case no mould was present, but it is possible that the oats in question might have been mity as well as mouldy.

\* The mould, it should be observed, was not confined to the bread in this instance, but was found equally on the wheat and flower of which it was made. The heat to which the fungus spores are exposed in the process of baking is not fatal to their vegetation, and accordingly almost before the bread was cold, the fungus began to grow in the inside of the loaves, which soon became a bright pink or salmon colour. The particular species of mould had not been previously observed by mycologists.

On the whole, then, it may perhaps appear doubtful whether the mould in the cases quoted above was the real cause of mischief, so much as the decomposition which the several substances had undergone, though it must be remembered that in such cases it is absolutely impossible to separate the parasite completely from the matrix on which it grows, the spawn or mycelium penetrating in every direction, and perhaps being equal in quantity to the threads which appear externally.

It is not necessary for us to enter into the peculiar symptoms presented by the several horses. It is sufficient to state that they were upon the whole such as would be caused by the administration of a narcotic-irritant poison, like that of fungi. Whether, however, the ill effects produced were due to decomposition of the oats themselves, or to the mould which grew upon them, the lesson is precisely the same, namely, to give a caution against the use generally of bad food. Mouldy hay and mouldy grain alike are sure in the end to be the dearest.\*

Should we be fortunate enough to obtain a sample, attention shall be paid to this and other matters arising from the question, which even in its present imperfect form can scarcely fail to be interesting.—M. J. B., in *Gardener's Chronicle*.

### Progress of Wages in Scotland and in Ireland.

At the monthly meeting of the Statistical Society, held at St. James's Square, London—Edwin Shadwick, Esq., C. B., in the chair—a paper was read by Mr. Frederick Purdy on the rate of agricultural wages in Scotland and Ireland. The writer commenced by referring to a paper on English agricultural wages, read by him in May last, and to the circumstances of the subsequent issue of a parliamentary return for Scotland, and one for Ireland, both modelled upon the English return, and both for the same period—the half year ended at Christmas, 1860. Dividing Scotland into three groups—viz., the northern, containing nine counties, from Shetland to Kincardine, the men's wages were 12s. 2½d. per week on the average; women's, 5s. 1½d.; and children's (under 16), 4s. That the men's average earnings by task-work were 13s. 6½. In three of the counties, men's harvest wages were 14s., 15s., and 19s. respectively. The midland group embraces nine counties, beginning with Forfar and ending with Bute. Here the men's wages were 13s. 2d.; the women's, 5s. 7d.; and children's 4s. The task-

work wages of the men 14s. 8d. a week. The southern group contained the thirteen remaining counties. The men's, women's, and children's wages were 13s. 2d. 6s., and 4s. 9d. respectively; the task-work wages, 15s. 3d. In some of the midland districts the harvest wages were very high, as, in Dumbarton, 21s.; Forfar, 25s.; and 26s. 6d. in Perthshire.

The statistics of the cost of the food consumed, and of the clothes worn by the Scotch peasantry, both in the present and the former times, were next treated of by the writer, with a view to illustrate the command which the money wages at the respective periods gave the labourer over the articles of his consumption.

The Irish returns were discussed under each province. In Ulster, the wages of the men during the half year averaged 7s. 3½d. per week; the women, 4s.; and the children, all the latter being less than 16 years of age, 3s. 2d. It was noticed that in Ireland the wages of one woman and of one child were together generally equal to those of one man; but that in Scotland the men's wages were considerably above the remuneration obtained by a woman and a child together. The task-work earnings of men in Ulster were 9s. 4d. a week. The Co. naught men had 7s.; the women, 3s. 1½d.; and children, 3s. 1d.; men's task-work, 8s. 10½d. In Leinster, men obtained 7s.; women 3s. 9d.; and children, 2s. 9d.; the task-work earnings of the men, 9s. 9d. Finally, in Munster, the men were paid 7s. 2½d.; the women, 4s. 3d.; and the children 3s.; the task work earnings of the men, 9s. 2d.

It appeared that taking the wages of the agricultural labourer as unity, the weaver was paid 1½, the shoemaker 2, the tailor 2, and the baker 2½, the carpenter 2½, and the bricklayer and mason 3 times as much at the same time and the same districts throughout Ireland.

The paper concluded by bringing the principal facts for the different parts of the United Kingdom together. It was shown that men's wages in England and Wales averaged 11s. 6d.; in Scotland, 12s. 9d.; and in Ireland, 7s. 1d. That in 23 years the rise in the English wages had only been 12 per cent., but that in Scotland, at an interval of twenty years, the rise was 42½ per cent., and in Ireland over 57 per cent. The fact of the low rate of increase in England, as compared with Scotland, was dwelt upon; there were special causes why the rate in Ireland, however gratifying, should not excite surprise. It was strenuously maintained that "the English wages were kept down by two causes—viz., the cruel and impolitic settlement of lands, and the large expenditure for out-door relief. Is it not manifest that when we distribute in England £3,000,000 a year, as untested relief, among the labouring population by the hands of the employers of labour, we place at the disposal of the latter an instrument as powerful as it is pernicious for depressing the fair wages of

\* Headaches are sometimes produced by the clouds of spores which spring up from the mouldy hay when taken in a stack; and the same effect has been observed to arise from the spores of such moulds as the common species of *Penicillium* and *Aspergillus* in other situations, when produced in excessive abundance.

the workman? It is well known that the lowest wages in England were paid in the most pauperised counties. But in Ireland, where there is no out-door relief, the least and the most pauperised provinces are on a par as regards the wages of independent labour; in Ulster, men's wages are 7s. 3½d., and that province has fewest paupers; but in Munster, the most pauperised, the wages are only 1½d. a week less? Taking corresponding districts in England, we find that in Northumberland wages are 14s., while in Dorset they are only 9s. 4d., or 30 per cent. less. Is there any escape from the conclusion?"

The Chairman, in proposing a vote of thanks to Mr. Purdy for his valuable contribution to the industrial statistics of the empire, observed "that there was one very important point of progress in an agricultural and social point of view, especially in Ireland—namely, the advance of the weekly wages beyond the money power of cottier labour and proprietary. In a textbook on agriculture by Mr. E. Murphy, the Professor of Agriculture at Queen's College, Cork, he sets down eight acres as the quantity of land workable at high culture by a farmer and his family, and that by the employment of a degree of skill not always found in large farms the money result obtainable by the labour of his family, and that, too, if they had no casualties, was £23 per annum, or say 8s. 10d. per week, or 1s. 3d. per diem, exclusive of milk and potatoes. Milk and potatoes were frequently given, plus the money wages stated in the statistics. But the average wages of the family, for man, woman, and child, had now risen to 14s. 5d. weekly on the average in Ireland, whilst in Scotland the family wages had got to 23s. 11d. weekly. The money power of these wages was greater than Burns' cottier or small farmer could get; more than Burns himself could have got. The wage family might feed better than he could on the produce of his small farm."

### Sea-weed as a Manure.

The utilization of waste products has occupied much attention of late years, both among manufacturers and agriculturists, and there can be no reasonable doubt but both these great classes of human industry will continue to reap many advantages by steadily pursuing a course of investigation in this direction. Sea-weed, of course, is only available in its crude form as a manure in places near the coast, so that by far the larger portion of Canada is precluded benefitting from this source. Sea-weed is extensively used as a manure along the coast of the New England States, and it might also be

in some situations on the Gulf and Lower St. Lawrence. In a recent number of the *Farmer's Magazine*, [English], we meet with the following observations:—

"The utilization of a common waste substance was recently brought before the public, in an admirable paper read before the Society of Arts by Mr. Stamford, on the useful application of sea-weed. From an elaborate chemical experiment which he had carried out, and a personal examination of the Scottish and Irish kelp works, he produced facts tending to show the great importance of this subject, and how much might be made of it in a commercial and agricultural point of view. It is not necessary that we should follow him into the chemical inquiry and the manufacturing processes and results, by which he proceeds to show how much may be done to add to the various commercial products obtained from sea-weed. Our business lies with the agricultural phase of the question, and how we may be able to diffuse some information of importance to many who have hitherto neglected, or else not duly appreciated, the rich stores which nature has so bountifully placed within their reach. In England generally sea-weed is little valued by agriculturists as an actual fertilizer, and appears to be regarded rather as an economical and useful covering to protect turnips and other roots from winter frosts. Farmers object to its bulk and expensive carriage—particularly now so many portable artificial manures are offered for sale, and recommended so strongly by their manufacturers as possessing great fertilizing value in a small compass. Mr. Stamford speaks strongly upon this. "There can be no question," he observes, "that many of these are worthless rubbish, and perfectly useless, except to line the pockets of the vendor; and the farmer would do well to turn his attention to the composition of sea-weed ash, which really does contain all the constituents of a good manure in a small compass." The ash from the charcoal, in making kelp, usually contains over 20 per cent. of earthy phosphates, the proportion being about that in Peruvian guano; and if the crude ammoniacal salt obtained by distillation were added, in the proportion of about 40 per cent., a manure would be obtained worth from £10 to £12 per ton, of which from 3 to 4 cwt. would be sufficient for an acre of land. The phosphate of magnesia it contains points to its special application to beet-root and clover—Mixed with about 5 per cent. of the chlorides of potassium and sodium, it would be equally beneficial to other root and cereal crops. Liebig divides crops according to their wants into three classes—potash plants, lime plants, and silica plants; such a manure contains the food for all or either of these.

The value of sea weed as a manure is most

appreciated in the channel Islands. Many of the agriculturists there use no other manure. The best drift-weeds appear to be torn up from the Atlantic, as they are found chiefly on the western coasts in Guernsey and Jersey. It is computed that about 30,000 loads of weed are annually obtained from the rocks and bays of Guernsey and the adjacent small island of Herm, valued at 2s. per load. The quantity collected at Jersey is fully as much. A great deal of drift-weed finds its way up the channel, and is washed in and out of the numerous harbours, and thrown on the flat coasts. Many thousands of tons of sea-weed are deposited annually on the coast of Sussex, but a small portion of which is utilized. The agricultural produce of the Isle of Thanet is said to have been tripled by the use of this manure, and the farms on the Lothian coast let for 20s. or 30s. more rent per acre where the tenants have a right of way to the sea-coast, where the weed is thrown ashore. Drift-weed is largely used in Ireland as the only manure for the potato crop, which requires a considerable supply of potash. The residual sea-weed ash from the iodine factories in France is highly valued as a manure, and constantly carried a distance of thirty miles from the factory. The agriculture in the western islands is also enriched by this manure, and some of the tangle is brought into Oban by fishermen, in boats, and sold at 1s. per load. On the south-east coast of Fife, it is laid on the stubble at the rate of 20 cart-loads an acre, and ploughed in; the clover crop never fails, and this is a crop requiring much phosphate of magnesia, an important constituent of sea-weed ash. In the Isle of Lewis 20 tons of sea-weed is considered ample for a Scotch acre. The meride algæ are valuable because the salts contained in them destroy foul weeds, hence cultivated fields on the sea coast are almost free from those noxious plants that infest the lands of the interior.—Sea-weed is used extensively for manure on the Cornish coast, particularly near Penzance, for the growth of early potatoes, and the land in consequence brings almost fabulous prices.

Great Britain alone, exclusive of Ireland and the Scottish isles, possesses a coast line of seven thousand miles, and it is assumed by some that sea-weed might be collected to an average of 3,000 tons per mile per annum. And yet out of this large natural supply but a very small proportion is collected and utilized. In its most prosperous days kelp was never manufactured to a greater extent in the United Kingdom than 28,000 tons per annum—an amount which would require about 560,000 tons of sea-weed. But the quantity now used in kelp making in Great Britain is scarcely more than a third of this. And yet the French manufacture nearly three times the quantity of kelp from sea-weed that we do.

In a new work published by H. Platt in 1601,

styled "The New and Admirable Arte of Setting of Corne," the author says: "Sea-kelps and sea-tangle and other sea-weeds are founde by experience to assist both arable and pasture grounds exceedinglie." "There is nothing new under the sun; but we may profit more generally than we do by the information thus given 260 years ago. Opinions will, however, differ as to the utility of sea-weed as a manure: some believe it to be good for one season, others that it is scarcely worth a mile's cartage. There can be little doubt of its utility as a fertilizer when easily obtained, and within a moderate carting distance."

## Agricultural Intelligence.

### Importation of French Merino Sheep.

A very superior flock of French Merino Sheep came over on the steamer *Zimmerman* from the United States, yesterday afternoon. The flock is composed of ten rams, and was imported into Canada by Mr. John D. Patterson, of Westfield, New York State, for the purpose of improving the breed of sheep in this country. The lot were all young sheep, but of very large size, and covered with fine silky wool, between three and four inches in length. Mr. Patterson is one of the most extensive breeders of stock in the Union; and he imported the French Merino Ram from France, which gained the prize of 450 francs at the World's Fair, held at Paris in 1855. Several of the sheep imported yesterday have already been purchased by some of the enterprising farmers in Vaughan and Markham. The others will be on view for several weeks at the Agricultural Implement establishment of Messrs. Patterson Brothers, Richmond Hill. While they were standing in front of the American Hotel yesterday, they were minutely inspected by a large number of citizens and many farmers, all of whom appeared struck with their large size and peculiar appearance, the animals being covered from the nose to the feet with long, compact, and beautiful wool.—*Globe*.

NEW YORK STATE AGRICULTURAL SOCIETY.—Col. B. P. Johnson, Secretary of the Society, has made arrangements to attend the International Exhibition in London, for the purpose of superintending such articles as may be forwarded from the United States. Mr. J. was the Commissioner from the State of New York to the first World's Fair, at London, in 1851, and performed his duties with signal ability, especially in the department of agricultural implements and machines, bringing them to the notice of other nations, and opening to our manufacturers and inventors an extensive and profitable field of business, and introducing improvements which have greatly improved and perfected the agricultural operations of the entire world.—*N. Y. Paper*.

### Hungarian Grass.

Our farmers have now been experimenting with this grass four or five years. Each succeeding season a larger breadth has been grown, and it may now, without doubt, be considered one of the standard crops of the west. Many of the extravagant claims at first urged for it have been laid aside, as have also many of the objections that, later, were brought against it. It is a prolific grass, yielding considerably more per acre than either the prairie or tame grasses, and is superior to the common millet, though not differing materially from it in its nature. Its seed is more oily, and consequently a heavier feed than millet, is a somewhat more vigorous grower, and hence a surer crop. Indeed, so deep rooted is it, that severe drouth does not affect it in the least, and may be sown upon the highest and driest soils without fear of failure. All kinds of stock, cattle, horses, sheep, and hogs are extremely fond of it, and when fed judiciously, we have yet to hear of an instance where any injurious effects have followed its use. Doubtless many horses have been injured, perhaps killed outright by its use, but these cases, to the best of our knowledge, are where the seed has been given immoderately, just as over feeding of any heavy grain will produce disease in animals.

Some have complained of its being an exhausting crop, but we think it has not been found more so than wheat or oats, certainly not more than buckwheat, and, like the latter crop, the ground is left in most excellent condition—light and free from weeds. Corn does well as a succeeding crop.

Hungarian may be sown any time from now to the middle of the month, and if to be cut for hay alone, perhaps the present season a little later. If for hay, sow one-half bushel per acre; if for seed, about one-third of a bushel is sufficient.—*Illinois Prairie Farmer*, June 7.

### Agricultural Productions of Nova Scotia.

Nova Scotia has already become somewhat famous for its apples. The crop is generally sure and large, and sorts which in England require a wall or espallier, will here grow and thrive in the open orchards as standards. In 1860 186,484 bushels of apples were raised in the Province—Annapolis County raising 65,405 bushels. Mr. R. Starr of King's County, and Mr. W. Chesley, of Annapolis County, contributed to the preliminary local exhibition at Halifax no less than 50 varieties of apples raised in their own orchards. The fruit attains an enormous size. A specimen of the "Gloria Mundi" sent to England measured from 15 to 16 inches in circumference. Hardy kinds of grapes, will, in the Western Counties, do well out of doors. During the past year the "Black Hambro" and "White Cluster" ripened in the open

air. The pear—hardy sorts—Plums, Cherries, and Tomatoes do finely—the latter fruit and ripen well in the open air. The Squash and Pumpkin have been grown of 140 and 170 pounds weight. Onions grow well and yield large crops—indeed, this may be said of all kinds of root crops. Specimens sent to England measure 17 inches in circumference. A native potato is found in the woods, which the Indians use as food. Potatoes yield on an average about 230 bushels per acre, and the tuber is less affected by disease than in other countries. In 1860 9,284,864 bushels were raised. Wheat, imperfect cultivation, yields from 25 to 30 bushels per acre—specimens sent to England weigh 62 and 64 lbs. per bushel. Barley is a sure and heavy crop; the Bald Barley will yield about 40 bushels per acre—specimens sent weighing 54 and 56 lbs. per bushel. In the Western Counties Indian Corn proves a most profitable crop, yielding 60 to 66 bushels per acre—specimens sent weigh 60 lbs per bushel. Buckwheat thrives well—specimens sent weighing as much as 56 lbs. per bushel. Garden and Field Seeds, of all kinds, grow remarkably well and produce profitable returns.—*Halifax Journal*.

WOOL EXHIBITION.—There is to be a great wool show under the supervision of the Ohio State Agricultural Society at its annual exhibition to be held at Cleveland, September 15th to 19th, 1862. Competition is open to the world. Wool will be divided into four classes. 1st. Fulling Wools. 2nd. Delaine Wools. 3rd. Cassimere Wools. 4th. Combing Wools. Twenty-five fleeces must be exhibited to entitle exhibitor to a premium. Mr. S. N. Goodale, of Cleveland, will have charge of this department.—*Prairie Farmer*.

### Horticultural.

#### Hamilton Horticultural Society.

[This Report came to hand too late for the last number.]

The first show of the Hamilton Horticultural Society, for the season, was held in the Mechanics' Institute, on Saturday, 24th inst, the anniversary of Her Majesty's Birthday. A day which the Society rejoice in celebrating, and in honoring by a production of nature's rarest beauties. The show was an excellent one, an honour to our ambitious city: creditable to the gardeners and their encouraging employer's; gratifying to the citizens who take an interest in the laudable objects of the Society.

The vegetables and fruits were few; but as much as could be expected for the time of the year. The winter apples were good, and

in an excellent state of preservation. Asparagus, Radishes, Lettuces and Rhubarb, good early Cabbage, fall-sown Onions, and early Potatoes very fair. The Floral department was the principal attraction; and on this occasion excelled any of the former at the same time of the year. The Geraniums were well grown, and fully flowered, many of the Foliage Plants rare and excellent. The Fuschias were much admired, particularly the lesser and double varieties. The Calceolarias, Gloxinias, Achimenes, and Green House Plants were much to be commended. The Amateurs made a very creditable appearance. In the collection of Foliage Plants from the Hot Houses of John Brown, Esq., there was a plant of the *Musa Cavendishii*; to this genus belong those universally esteemed fruits, the Banana and Plantain; they are by some called the Indian Bread Trees. Some of the species grow to the height of twenty-five feet, and are rarely cultivated to any extent out of their native tropical climates. The *Cavendishii* is a native of China; its dwarfish habits render it suitable for any plant stove or warm Conservatory, where it may be cultivated with success: its ordinary height is about five feet. Sir Joseph Paxton represents it as a most valuable species. Some authorities maintain that no known plant produces so much nutriment from the same space of ground as the Banana. Of the numerous uses to which it is applied, the following may be mentioned: the tops of young plants are eaten as a delicate vegetable; the fermented juice produces an agreeable wine: and the fruits may be dried and ground into meal, served up raw and stewed. Slices fried are said to be a fine delicacy; and finally the leaves are used for thatching and basket making. Charles Lees, Esq., exhibits in his collection of Green House plants the *Ornithogalum Squilla* (By Linnæus *Scilla Maritima*). It is a native of Sicily, Syria, Greece, Barbary and Spain. The bulbs of the *Ornithogalum Umbellatum* have been eaten from time immemorial by the Persians. They are roasted like Chestnuts, and eaten with oil, vinegar, and pepper by the Italians; and they are thought by some writers to have been the dove's dung which was sold for five pieces of silver during the siege of Samaria, in the reign of Ahab.

## PRIZE LIST.

Achimenes, best six in pots, Thos. Buchanan, gardener to W. P. McLaren, Esq. 2nd do, do; Begonias, best three, William Hill, gardener to John Brown, Esq. Varieties, Marchall, Rex, President V. Vandem Heeke. 2nd, Thos. Buchanan; varieties, Grandis, Marchalli, Madame Wagner. Calceolarias, best four in pots, distinct varieties, William Hill. 2nd, Thomas Buchanan. Best specimen, Thomas Buchanan. 2nd, Robert Murray, gardener to John Young, Esq. Cinerarias, best four in pots, Thomas Buchanan; varieties, Magenta (new), Beauty of Chestnut Park, Mrs. Goodfree, Countess of Rox-

borough; 2nd, R. Murray; 3rd, William Hill. Foliage Plants, best six, William Hill. Varieties, Maranta Teybrina; Croton, tricolor; C. Pictum; Caladium Chantini; Dracaena Terminalis; Cissus discolor. 2nd, Thos. Buchanan. Varieties, Cissus discolor, Dracaena terminalis, Croton Pictum; Caladium tricolor, Dffenbachia picta, Mananta Teybrina. Gloxinia, best six, 1st & 2nd, Thomas Buchanan. Fuschias, best four distinct varieties, William Hill. 2nd, R. Murray; 3rd, William Hill. Double best, three distinct varieties, R. Murray; 2nd, William Hill; 3rd, do, do. Best single specimen, R. Murray; 2nd, William Hill; 3rd, do, do. Geraniums, best four, R. Murray. Varieties, Sir Henry Smith, Elegans, Reine de Belle, Arnold's Virgin Queen; 2nd, Thos. Buchanan. Varieties, Marie, King, Butterfly, Arnold's Virgin Queen, Sir Henry Smith. Best single specimen in this class, R. Murray; 2nd Thos. Buchanan. Fancy Geraniums, best four, William Hill. Varieties, Itolinskii, Cloth of Silver, Jeannie Deans, Morning star; 2nd, R. Murray. Varieties, Miss Allan, Jussieu, Superb, Additta, Itolinskii; 3rd, Wm. Hill. Best single specimen, William Hill; 2nd, R. Murray; 3rd, William Hill. Scarlets or other colors in the class, best four, Thomas Buchanan. Varieties, Beaton's Nosegay, Mons. Martin, Christina, Mrs. Fielding; 2nd, Wm. Hill. Best single specimen, R. Murray; 2nd, William Hill.

Green House plants, best twelve, Thomas Buchanan. Varieties, Vinca Alba, Angelonia gardenieri, Clerodendron fragrans, Vinca rosea, Stephanotis floribunda, Lantana Alba, Erica Ventricosa brivefolio, Hydrangea Nortensis, Calceolaria rugosa, C. Pallidior, Pentas carnea, Calceolaria, D. O'Connell. 2nd, William Hill. Varieties, Pentas carnea, Pentas rosea, Gardenia radicans, Gardenia florida, Allamanda neriifolia, Heya Bella, Polygala oppositifolia, Centradenia rosea, Erica alba, Erica Ventricosa Superba, Erica humalis, Asclepias salicifolia. Best six, R. Murray. Varieties, Asclepias salicifolia, Myrtus belgica Hydrangea nortensis, Calceolaria rugosa, Calceolaria pallidior, Cytisus racemossus. 2nd, William Hill. Varieties, Tollya netrophylla, Cuphea emines, Cyticus racemosus, Cuphea parviflora, Calceolaria rugosa, Erica Beaumontiana.

Ferns, foreign, best six, Thomas Buchanan. Varieties, Pteris agria, Pteris tricolor, Gymnogramma chrysophea, Adiantum pubescens, Lastræ glabella, Asplenium pinucilatam; 2nd, Wm. Hill. Varieties, Gymnogramma peruviana, Pteris Sagittifolia, Todia Pellucida, Asplenium Belangeri, Pteris tricolor, Acrostichum alciocore.

Natives cultivated, best six distinct varieties, Wm. Hill; 2nd, John Freed.

Herbaceous plants, best six Spikes, John Freed.

Native plants cultivated, best six distinct varieties, Wm. Hill; 2nd, Wm. Sanderson.

Pansies, best 12 distinct varieties, Thomas Buchanan; 2nd, William Chapman, gardener to Isaac Buchanan, Esq., M.P.; 3rd do. do.

Roses, best six cut blooms, 1st and 2nd, Thomas Buchanan.

Shrubs, hardy, best six spikes, distinct varieties, John Freed; 2nd, Thomas Buchanan.

Tulips, best 12 distinct varieties, Thomas Buchanan; 2nd, Bruce & Murray; Verbenas, best six in pots, distinct varieties, Thomas Buchanan; best 12 truses, John Freed; 2nd, William Chapman.

Bouquets, best hand, Thomas Buchanan; 2nd, William Chapman; best table, Thomas Buchanan; 2nd, William Hill.

#### AMATEUR CLASS, WITH SMALL GREEN HOUSES.

Green House Plants, best three, George Carlisle, Esq.; 2nd, Charles Lee, Esq.; Geraniums, best three distinct varieties; C. Lee, Esq., Cottage Window Plants, best specimen, Mrs. Sharp.

#### LADIES' FLORAL DEPARTMENTS.

Best Hand and Table Bouquet, Mrs. C. Lee.

#### SPECIAL PRIZES.

By W. P. MacLaren, Esq., Calceolarias, Herbaceous, best six distinct varieties in pots, Wm. Hill.

By D. L. MacNabb, Esq.; Tulips, best 25 distinct varieties, Bruce & Murray.

By M. Murray; best Table Bouquets, William Hill.

By W. Michael; Geraniums, Fancy, best six; William Hill.

By J. H. Greer, Esq.; Ferns, foreign, best six, distinct varieties, Wm. Hill.

By John Freed; Pansies, best three distinct varieties in pots, Thomas Buchanan.

By John Brown, Esq.; Green House Plants, best twelve. Varieties, *Torrenia asiatica*, *Bouvardia linthea*, *Ardisia fructo alba*, *Ardisia crenulata*, *Cleome dilleniana*, *Justicia speciosa*, *Calceolaria rugosa*, *Asclepias salicifolia*, *Ereca tricolor*, *Hydrangea*, *Japonica protensis*, *Euphorbia fulgens*, *Cuphea platycentra*.

By John Brown, Esq.; Foliage Plants, best six, William Hill. Varieties, *Musa*, *Cavendishii*, *Cissus discolor*, *Manantu Zebrina*, *Traacaena terminalis*, *Pavetta borbonica*, *Dieffenbachia maculata*.

By G. L. Reid, Esq.—Fuchsias, best six varieties, not to exceed 5 feet in height, R. Murray.

#### FRUIT DEPARTMENT.

Best twelve apples of one kind, 1st and 2nd, William Chapman. Best and greatest variety of Apples in the best state of preservation, not less than 6 varieties, William Chapman. Cucumbers, best brace, Thomas Kilvington; 2nd, William Hill.

#### SPECIAL PRIZES.

By T. C. Kerr, Esq.—Apples, best twelve, Rhode Island Greening, William Chapman; Baldwin, Charles Depew; Russets, C. Depew.

By William Holton, Esq.—Northern Spy, C. Depew.

By R. Bull, Esq.—Best collection, three of a sort, Thomas Lottridge.

By George Laing—Cucumbers, best brace, William Hill.

#### VEGETABLE DEPARTMENT.

Asparagus, best twelve heads, William Chapman; 2nd, R. Murray; 3rd, Thomas Buchanan.

Cabbage, early, best three heads, Wm. Hill.

Lettuces, best four heads, William Hill.

Onions, seeding, best twelve, fall sown, Thos. Buchanan. Red, best six, of 1861, best state state of preservation, T. Kilvington; 2nd, A. W. Taylor. Yellow, best six, A. W. Taylor.

Parsley, curled, best bunch, A. W. Taylor.

Potatoes, kidney, best 2 quarts, Wm. Taylor.

Radishes, long, best twelve, H. B. Bull, Esq.

Turnip, do, best twelve, A. W. Taylor.

Rhubarb Stalks, best six, John Freed; 2nd, Thomas Kilvington.

Spinach, best peck, A. W. Taylor.

#### SPECIAL PRIZES.

By J. M. Williams, Esq.—Asparagus, best twelve heads, Thomas Buchanan.

By R. Osborne, Esq.—Lettuces, best six, William Hill.

By J. Wilkes, Esq.—Potatoes, kidney, best quart, William Hill.

By James Gay, Sea Kale, best six heads, William Chapman.

By J. M. Williams, Esq.—Spinach, best peck, A. W. Taylor.

By W. Hill, Parsley, curled, best bunch, William Hill.

By H. Shaw—Rhubarb, best six stalks, John Freed.

#### EXTRA BY SOCIETY.

For Indian Onion Plant, *Ornithogalum squilla* and *Caetus*, Charles Lee, Esq.

The Judges, Messrs Fleming and Young of Toronto, and Messrs. Holden and Tackel from St. Catharines, expressed themselves highly pleased, especially with the Foliage Plants and Geraniums.

GEORGE LAING.

Hamilton, 30th May, 1862.

### On the Decay of Orchards.

There is a general complaint in New England, Canada, and the Western States, that old orchards are dying, and that young orchards do not flourish as well as they formerly did. Various causes are assigned for this, and no doubt there is more than one cause for the evil. We are inclined to the belief that the principal cause is the action of borers, for there are undoubtedly more than one species of this scourge. One kind, and the most destructive species, is that which attacks the tree near the ground, and does its mischief by girdling the trunk of the tree (*Supera Bivittata*.) This most gen-

erally commences just at the edge of the ground, where it will be out of sight, and works upward and around the trunk, and is oftentimes never suspected. It is some time doing its mischief, and where it does not completely encircle the tree with its channel, or groove, it (the tree) will live a sort of lingering, feeble life several years, and finally die.

We once set out some trees from a nursery, that had been perforated near the ground by borers. We examined them carefully, and were sure that they had been all got out. The tree grew very well, and bore fruit a year or two, but finally dwindled down and died, in spite of all the care and nursing we could give them. On examining them after death, we could find no apparent cause for their death but the perforations that the borers had made near the collar of the junctions of the trunk and roots before they were transplanted. It had not peeled, and the water and continued moisture getting in caused a gradual but final decay.

We said that there were several species of these borers. Some think that the one mentioned above never meddles with the branches of trees; but there are those that do. We have found at least two kinds doing mischief on or rather in the branches. One kind is rather small and seems to confine its operations between the bark and the wood. We have always found it there. The bark is always black and decayed above its lodgment, but whether the egg that produces it is laid there before the bark has been killed or after, we are not able to say.

There are other branch borers that plunge into the wood and burrow about with a *gimlet* in their heads, that seems to enable them to go anywhere about the limb they want to. We cut off a large limb of an apple tree the other day, that we supposed was killed by the cold weather some winters ago, and found three of these last named fellows in it. From their size and the extent of their galleries we are led to change our belief of the cause of the limb's dying, and attribute it to the borer. It is possible, however, that we are wrong in this, and those we found belong to that kind that operate only in wood already dead and decaying, as there are some such.

The apple tree, like other fruit trees, has its peculiar and specific enemies. We wish that friends Packard and Brackett would make the study of them a specialty for a time, and give us a treatise on apple-tree insects—their habits and their remedy.—*Maine Farmer.*

### Trees and Rain.

The following remarks from a recent number of the American *Agriculturist*, are deserving of the serious attention of the owners of wooded lands:—

"It is plain to every observer, that our coun-

try is now more subject to drouths than it was twenty or thirty years ago. Within the last five years we have suffered in this respect seriously. The loss to the farming community, and through it to the whole population, has been many millions of dollars. If they continue for several years more, in frequent succession, there is a reason to fear that the "hard times" will pass away very slowly. Is there any natural cause of drouths, or are they sent upon us solely as special visitations of Providence for our national sins? We would not speak lightly of such visitations, but we are inclined to think that our sufferings in this particular may be traced chiefly to our own bad management. The wide destruction of our forests doubtless has something to do with the production of drouths, and of these destructive floods or "freshets" which are becoming alarmingly frequent.

If the country is widely denuded of its trees the land is more exposed to the burning rays of the sun, and to the winds which cause a very rapid evaporation. Then, too, forest-trees are so many pumps to suck up moisture from the depths of the earth, and to diffuse it through their leaves into all the surrounding atmosphere. From thence it falls upon the surface of the ground. Perhaps some of our readers have amused themselves with making estimates of the amount of water evaporated from the leaves of a single tree, and then of a large forest, in a single day. To one who has never thought about it, the subject is one of great interest. All readers of history know that many of the rivers and streams of the old world, which once were wide and deep, have now shrunk into much smaller dimensions; from what cause can any one tell, if not the hills and mountains are now almost entirely bereft of trees? Drouths prevail all over the eastern continent, with increasing severity; and scientific and observing men everywhere proclaim that this is owing chiefly to the cause of which we now speak.

Valleys and lowlands, and fertile plains should of course be cleared of trees and devoted to farms and gardens; but at least the rocky hills and mountains should not be shorn of their leafy honours. Let the trees stand sacred from the desolating axe, all along our heights, to break the fury of storms, and to condense and bring down the useful vapours of the clouds upon fields and into our springs and streams. It is high time that the older States of the Union began to move in this matter, either regulating the destruction of our old forests, or encouraging the growth of new. We believe that some wholesome law touching this matter would both secure our posterity a good supply of lumber, and a good degree of exception from drouths.

All that individuals can do in this matter is to preserve their own forest land in just proportion and by underdraining, thus deepening the soil, and giving it a porous spongy character, render the land capable of absorbing and retaining as

large a quantity as possible of the water that falls upon it, instead of allowing a large portion to flow off as is now generally the case. Our State Legislatures might we think with great propriety remit the taxes for 20 years on all land devoted to high forest, (not low woods for charcoal and hoop poles) and tax land which might but does not carry a good growth of high or low woods at the rate of its value would warrant if properly improved.

### Are Cottage and Farm Gardens Cultivated to the best advantage.

It is really astonishing how precious the worldly denizens of the cottage and the farm cling to the use and wont system of preparing the ground for the reception of both vegetables and flowers. All the lecturing of horticultural and agricultural writers will not suffice to drive some of them one peg of their usual routine. If you advise some of them verbally how futile it is, comparatively speaking, to be satisfied with the doing out of a certain quantity of manure year by year, and only digging their ground some eight or nine inches deep, when less manure, and digging or trenching twice the depth, would be more satisfactory in the aggregate, producing culinary examples far more palatable, and not only imparting a sounder constitution to the respective examples of plants, but a more lengthened existence to the flowers that decorate their borders, some gravely aver, in reply, that the system which they have adopted and practised many years has been upon the whole satisfactory; that, with due reference to your ideas, they as yet have seen no cause to modify or revolutionize a system practised by their fathers before them—in a word, they have no inclination of giving ear to such new-fangled notions, probably exchanging certainty for hope. Others again, less arbitrary in their notions, admit that your suggestions and arguments are very feasible, but excuse themselves upon the plea of onerous duties during the day, and further, submit that it has, hitherto, required all their spare time in the evenings to get their seeds into a proper bed at the proper time. In fact, there are no end of excuses where parties are disinclined to try a method novel in their ideas.

It does not require much logic to meet these and such like argument—indeed, they have been combated over and over again. They are the fragments of an obsolete system, and must explode betimes on the age of progress.

Deep digging offers a powerful inducement to the industrious cottager of obtaining by a little extra labour, a larger return with less outlay; and few cottage gardens are so inconveniently large as to preclude the tenant, if he wills, bringing it to the highest point of cultivation.—Manuring alone will not produce a high state of

cultivation, but the whole secret lies in deep trenching. A high state of cultivation depends, in the first place, on the land being properly drained. All the foreign matter you can introduce has a qualified effect until his operation is efficiently performed. Deep digging is the next essential, and it has many collateral advantages. It ameliorates the character and condition of the soil in many ways; it offers the least obstruction to water in its passage down ards, and consequently raises the temperature; it is more thoroughly aerated—more exposed to the action of the atmosphere, which adds powerfully to the nutrition of the growing plant; while, at the same time, the roots revel in the loosened staple in a way unknown to the best examples of land superficially treated; its chemical ingredients, in many instances, are materially reinforced by bringing up the subsoil, and that is of very great importance; it is one of the best means for getting rid of slugs.

If ground be trenched three spits deep in the spring there will be few—very few, indeed—to make their appearance in that quarter, unless there be a plot of grass contiguous, or a strong row of box edging, which holds enough to pollute any quarter of ground in a garden, however large. It is curious that a great number will find their way to the surface on ground that is trenched two spits deep, but a thirty-inch staple will be found a deep enough grave for those troublesome pests to the vegetable creation.

This is an important consideration for all holders of small gardens, ay, and large gardens too, to take into account, especially those who have tenacious soils, rich in alumina, and proportionately backward for generating and assisting the development of crops in the early season. Many of the small seeds when in an embryo state fall a prey to those marauders, and often the blame is attached to the unfortunate vendor. It kills all that it comes in contact with for the time being, but it is impotent in its effects twelve hours after application. Surely, then, deep digging, if it offers so many advantages chemically and physically, with the chances of being less pestered with these devourers of germinated seeds and young fresh plants of the Brassica section to boot, is worthy of the best farmer's, the best gardener's, and the poorest cotager's highest consideration.—JAS. ANDERSON, Meadowbank.  
—*Scottish Farmer*

### Onion Culture in Massachusetts.

The amount of onions raised on the Sea-board of some of the New England States is almost incredible. We saw hundreds of acres while on a tour some years since. Women are extensively employed in the culture, and the crop, although very variable, is often highly remunerative. Vast quantities of onion seed is annually saved, and our market gardeners in Canada greatly prefer it to

that imported from Europe. A Massachusetts correspondent of the *Country Gentleman* under date of May 8th, facetiously remarks :

Free rains—cool nights and mornings, Cultivators are embracing every fair moment to put in their seed. Many a pound of onion seed has been buried alive within a week. Notwithstanding the depredations heretofore made in their crops, still they are planted in hope—or even half a crop of onions pays better than any other crop that can be grown in our fields. No man may expect more than \$20 net income from a field of grass, or \$30 from a field of Indian corn ; but even a moderate growth of onions brings in one hundred *shiners*. Why not, then, go in for that which pays best ? There is no danger of glutting the market. Heretofore, all that have been raised have been readily sold at fair prices.—Onions pay better at fifty cents per bushel, than corn at one dollar, or hay ten dollars per ton ; thus the shrewd calculator will spare no effort in growing onions. They have this merit ; they do no one any harm, and if they make delicate ladies turn up their noses occasionally, it may enable them to show their teeth to better advantage, provided they are not *false* or *rotten*—and if they are, the sooner they learn to amend their ways, the more to their credit will it be.

### Raspberries.

The master seeing his men very busy in doing "nothing," asks the following question, and gets the following answer, "John, what are you doing ?" "Nothing, sir," "William, what are you doing ?" "Please, sir, I was just looking after John." "Very good. Here is March come upon us ; I will see if I can't find better employment for both of you. Get Parke's fork, and go into the Raspberry-bed ; take up the runners, and fork the bed all over : mind there is nothing like deep cultivation !" This is tolerably well obeyed by John and William. Now, I ask any man how he can expect to have a crop of raspberries after this fashion ? Not only are the old roots broken, but the new spongioses are broken also ; and the roots being turned up to sun, and wind, like the ends of skates, of course the crop dwindles away.—Hence a man comes to the absurd conclusion that the garden will not bear strawberries and raspberries. Look at the gardens of England generally, and you will find that, except in wet, dripping summers, there are neither of these fruits. Never disturb the ground at all ; hand-weed, and cover the whole soil with stable litter from the horse, with a little black manure round the stools, and you will have more raspberries than you know what to do with. If the summer is very sultry, give each stool one bucket of water twice a-week. A raspberry, like a woodcock lives by suction. From three to five

canes are enough, and these should be cut down to 3 feet. You will get as much fruit by this height as if you left them eight feet high. In a word, the dormant eyes at the base will break, protect the young canes, and keep off the sun. Mine are strong, and are cut to an average of 2 feet 9 inches. I have only one sort, the Beepot [red,] which with this treatment never fails.—The crop last year was enormous ; but, for want of sun, lacking in flavour. Under proper treatment it cannot be too hot for raspberries and strawberries. Weak liquid manure and Peruvian guano one small handful to a stable bucket of water, will greatly assist. With regard to forking the ground, I must observe that I have not moved mine for the last four or five years. If you do move your ground, instead of your new canes coming up close to the stools, you will have them all over the bed.—The candle will burn at both ends, and in the middle too. Keep all runners down except those close to the stools. The closer the ground is kept down the greater will be your crop.—High manuring upon an undisturbed surface are two main features in growing raspberries and strawberries. No man tears out the stomach and entrails of his horse and pig in order to fatten them ; but this is what a man does when he despoils the roots and rootlets of his plants. I am encouraged to make the above remarks by the numerous letters of thanks, which I have received from your readers, in different counties for my strawberry article. The preparation for raspberries is precisely the same as for strawberries. I think the best distance is a yard from plant to plant, and from row to row. The following raspberries are well spoken of by Mr. Rivers, in his noble catalogue of fruits. Red Antwerp, Yellow Antwerp, Fillbasket Fastoff [red], vulgarly called Falsstaff ; Curhills' Prince of Wales [red], Carter's Prolific [red], I have tried the Red Antwerp and Fastoff : but they bear no comparison for canes and crop to the Beepot, which, I suppose is the same as Kuevett's Giant ; moreover, it never blights. Finally, what a pity it is that John and William should work so hard—first, in doing nothing ; secondly, in doing worse than nothing ; and that men generally who possess so acutely "five senses," should be so lacking in the sixth and best of all, "common sense."—W. F. RADCLIFF, Rushton Rectory.—*Florist and Pomologist*.

### The Dairy.

#### Hints on the Art of Butter-Making.

In order to make pure butter, something is required besides the good breed of cows, the sweet grasses, the soft springs, the rolling lands, the rich milk, the most experienced churners,

and the most improved machinery; the best material may be manufactured into yellow grease instead of butter, unless the process is properly performed. It is a fact too well known to dairy-men, that the butter is not made by agitating the milk—not by the process of churning. Butter already exists in the milk, and the art of separating it from the milk, is that on which the success of the dairy depends. Butter exists in globules so small as to defy the detection of the eye, unaided by the microscope, and the removal of these globules without crushing them, is the delicate and difficult task the dairyman has to do. There is no luxury that comes to the table which is so exquisitely sensitive as butter. If the cow feeds on white clover, the butter has a white clover flavour; if she feeds on cabbages, the butter has the flavour of cabbage; if the butter is kept in the vicinity of the stable, it forthwith becomes tainted with the smell of the stable; if packed away in pine tubs, it catches the taste and odor of the pine. It requires skillful handling or it will certainly be spoiled. If there is too much rubbing in the churn, these fine globules, mashed and crushed against the sides of the churn, will give greasy butter; and if the air is excluded the gases will injure it. What can be done, you inquire to cause the adhesion of the globules without grinding or breaking them. Experienced churners answer the question, when they caution young beginners not to churn too fast; not to heat the milk too much; not not to overdo, &c. They may not it in every instance understand the philosophy of the fact, but they do know the fact, that 'overdoing' make grease and not butter. The seasoning of butter is a matter of taste, and there are a great many persons who imagine that the more salt they put in butter the better it keeps. That is a great mistake. Just enough, and none too much is what is required. Too much will spoil the taste and not save the butter. Without penetrating any deeper at present into the philosophy of butter-making, we will simply add, that a gentle and uniform agitation of the milk will best reward the butter-maker for his pains. The butter should be kept away from all unpleasant odors, and when put down should be packed in white oak tubs. Clean cows, clean stables, sweet pans and churns, and neat and tidy operators, are among the things desired by those who would send pure butter to market.—*Am. Ag.*

## The Poultry Yard.

### What Ails my Fowls?—Hen-Pecked Husbands.

In response to the above question, proposed by A. A. N., in the eleventh number of current volume of *Country Gent.*, we would remark that

in regard to the falling off of the feathers of his fowls, there is not so much of disease as habit, caused as we think, by a morbid appetite, apparently induced in the outset, by the impatience of the fowls under confinement, and possibly for the want of gravel, calcareous matter, and animal food, which they obtain when at liberty, in the way of worms, grubs and insects. That it is habit, is evidenced from the fact that the hens are the aggressors, and are guilty of "hen-pecking" their husbands. We have noticed also that the cocks are the victims; they will stand and suffer the hens to pick not only the feathers from their heads, necks and backs, but even the flesh to the bones, and sip the blood as it drops from the wound; and what is singular, they will stand with their heads down, and suffer themselves to be robbed of their flesh and blood, and be denuded of their feathers without the least resistance! The habit is difficult to cure, and we have known it kept up till some of the individuals of the flock who were made especial victims, were almost entirely denuded of their feathers, and in some cases have even had their entrails torn out. Sometimes a particular fowl shows a more inveterate disposition to eat feathers than the rest of the flock. It is best, if not very valuable, to kill such—at any rate remove them from the others. We have never known fowls when at liberty, to be guilty of this foul habit.

The best prevention or preventives are animal food, broken bones, oyster shells, pulverised charcoal, varieties of grain, pure water, clean, and well-ventilated apartments, with a free range, and we will venture to say you will not be mortified by seeing those ragged, half-denuded rough-looking objects about the premises.

The wants of poultry are very clearly shown by a correspondent of the Boston Journal, in the following amusing sketch: "A most pleasing illustration," says he "of the want of lime, and the effects of its presence, came under my notice on my voyage from South America to sunny France. We had omitted to procure gravel for our poultry, and in a few days after we were at sea the poultry began to droop, and wound up their afflictions with the pip, or as the sailors term it, the scurvy. Their feathers fell from their bodies, and it was perfectly ludicrous to see the numerous unfeathered tribe in the most profound misery, moping away their time in an utter state of nudity. Amusing myself one day, by fishing up gulf weed, which floated in immense fields upon the surface of the ocean, I took from it numerous small crabs about the size of a pea. The poultry with one accord, aroused themselves from their torpor, and seemingly aware of the therapeutic qualities of these interesting animals, partook of them with greater avidity than an invalid ever swallowed the "waters of the springs" After a few hours the excellence of the remedy was apparent; the

cocks began to crow, the hens to strut and look saucy, and in a few days all appeared in quite a holiday suit of feathers, derived from the lime, the constituent part of the crab shells.

M. Sace of Switzerland, gives an account of some experiments in the feeding of domestic fowls. He states—first, that the fowls to which a portion of chalk is given with their food, lay eggs, the shells of which are remarkable for their whiteness. By substituting for chalk a calcareous earth rich in oxide of iron, the shells become of an orange-red colour. Secondly—he informs us that hens fed on barley alone would not lay well, and that they tore each others' feathers. He concludes that this proceeding arose from the desire of the hens for azote food.

New-York, May, 1862. C. N. BEMENT.  
(Country Gentleman)

## Veterinary Department.

(Conducted by A. Smith, V. S.)

### Diseases of Bone—Splints.

Bones constitute the skeleton and are for the purpose of giving support to the body, protecting various delicate organs also for locomotion. It is to the different bones that various muscles are attached, and owing to their acting as levers the different movements are performed.

Bone is covered by a thin fibrous membrane, called the *Periosteum*, which is strong and varies much in thickness, being thickest in those parts least covered by muscle. When this membrane becomes inflamed, lymph, a product of inflammation, is thrown out between the periosteum and the bone, the lymph becomes converted into cartilage, and this again into bone; this when occurring on certain parts is called *Splint*.

Splint is a bony enlargement technically called an *Exostosis*, and the usual situation is below the knee, and between the large and small splint bones; it also occurs on the outside of the leg, especially with horses having the toe somewhat turned in.

Splints are of most common occurrence on young animals, and the reason is that at their period the periosteum is largely supplied with blood, and it more readily takes an inflammation, and the effused products are very abundant, and shew a great tendency to become transformed into osseous structure.

Suppose a young horse is put to fast work on hard roads when the feet are subjected to concussion; the result of this tells on those bones which are most solid and upright, hence splints occur on the shank bones, and generally on the inside.

Splints seldom cause much lameness unless when rapidly deposited. When occurring on both sides of the limb and especially when accompanied by bony enlargements about the pasterns, they indicate weakness, a tendency to

bony growths, and a consequent liability to lameness. When situated close to the knee, splints sometimes produce a great degree of lameness, from interfering with the articulation, in some cases are very difficult to detect, are apt to be overlooked, and may prove a very obstinate lameness.

*Action produced by Splints*.—The animal may walk sound, when trotting he has a drooping gait, and not with the bending of the knee.

*Treatment*.—When inflammation exists, either hot fomentations or cold applications should be used, or if practicable let the horse stand for an hour several times a day, up to the knees in a pool or stream of water, and allow perfect rest for ten days or a fortnight. When heat and tenderness are removed, if lameness still exists, setons are most useful, or, in some cases, the operation of Periosteotomy give instant relief—that is dividing the periosteum.

When splints do not cause lameness they should not be interfered with, as on a well formed leg, and situated low down, they do little harm. Firing and blistering is sometimes had recourse to. A seton, however, is preferable, its effects being more lasting and not so apt to leave a blemish.

### The Brood Mare.

The question has often been discussed as to whether the sire or dam exerts most influence on the produce. We have usually observed these discussions to be conducted under predetermined notions, instead of seeking to unravel facts with a view to arrive at logical conclusions. Breeders of thorough bred horses alone seem fully to understand the real importance of attending to the qualities of both sire and dam, and that until the exercise of judgment and proportionate good fortune favouring, the latter is obtained, the former cannot be availed of. That good weight-carrying horses of mixed breeds have become annually more scarce during the last thirty years, few people will deny, and most men who are interested in the subject are of opinion with ourselves, that one of the chief deteriorating influences has been a want in appreciation of the value of the mare on the part of farmers. The foregoing observations apply especially to the best breeding districts in England, taking, for instance, the East and North Ridings in Yorkshire. Any one who remembers the fine Cleveland bays, the coaching and hunting mares of years gone by, with those of the present time, will acknowledge that these have become scarce in number and inferior in quality as compared with the same class of former times.

We have asserted the want of understanding the real value of the mare has been a primary cause to check improvement, and has produced loss to the country of the best mares—those

adapted to produce carriage horses, hunters and roadsters. Let any one offer what is considered a good price, and the best brood mare in the district is taken away, and the breeder, without any reason, congratulates himself that he has made a good sale, and has turned in ready money, whilst he has, probably a bad, long-legged filly, in no way calculated to become a brood mare, which he none the less keeps to supply the place of the good mare he has sold; this has been of constant occurrence, the mares not being sold from one farmer to another, but to leave the country. Again, of late years mares have been more used in towns than formerly; they have brought better prices in the market: hence another inducement to sell very good animals. There were also some causes between twenty and thirty years ago which led to many farmers parting with their good mares. It was when railways were first established that many took alarm, and believed that horse-breeding would no longer prove remunerative. A little previous to that time, when roads were being macadamized, the streets of London improved, and light carriages substituted for heavy, and the continental dealers became the best buyers—those from Paris especially being amongst the best judges in the market—the old-styled strong class of coach horse was objected to; these men wanted good heads, good action, in fact, good horses with breed. This new demand on the part of the dealers ready to buy at high prices when they found the horses they wanted, led to a more extensive use of blood stallions with the coaching mares; and had these horses been of the right sort, the result must have been good; but for the most part, the blood horses were amongst the worst that could be found for that purpose, overgrown, leggy animals, with flat sides and bad feet, and many produced stock that was really no good at all. Reared on rich grazing lands, the young stock from such crosses grew fully as high and more lengthy than the old coach horse, but with a want of power, action, and wearing qualities; simultaneously with the change came a great increase in the number of roasters. It was soon seen that narrow, long-legged horses would not do for work, nor would they sell to pay; but it was not so easy to retrace the steps. The bad colts could be got rid of at one price or another, but the fold-yard and the field became stocked with bad fillies; the wide, good, old-fashioned mares disappeared; it is true there were always a few good ones left, and there are some still, though they are scarce. We wish to show the tenant farmer that it is to his interest to incur a liberal outlay for the best young mare he can find in the country, and then equal good judgment in the selection of a stallion, though he go some distance in search of him, and to continue the process by equally good management of his stock in all seasons. A valuable brood mare to an intelligent farmer is like his richest field, re-

quiring good seed and diligent cultivation, and then, not otherwise, will horse-breeding prove a profitable branch of agriculture.

This subject which has been at other times treated in our pages, we have been induced to notice again at this season, through looking over the columns of *Bell's Life*, in which are so often to be found the names of horses with their merits so set forth and tabulated as to be readily seen at a glance; we have been struck by the perusal of the list of stallions to see that five of the most fashionable of the present day are sons of one mare. We shall comment on this progeny, because it so fully supports all our notions respecting the value of the brood mare, and illustrates what we have said in the foregoing paragraphs. The stallions Stockwell, Rataplan, King Tom, Knight of St. Patrick, and the Knight of Kars are all sons of the Marquis of Exeter's mare Pocahontas; we venture to say that no such example in the value of the produce of one living mare can be adduced. We shall not now multiply this value by adducing the second generation of this extraordinary animal; they are yet young, though one stallion from amongst them, a St. Leger winner, St. Albans, is just advertised to cover at 20 guineas a mare, whilst Kettledrum and others will succeed in due time.

For the instruction of some of our readers, we will give the prices at which these five stallions are advertised to cover: Stockwell at 50 guineas a mare, Rataplan and King Tom at 40 guineas each, and the two last named untied stallions respectively at 30 and 10 guineas each. The horse at the head of this list has had his subscription full for some months past, and no doubt the next two have their allotted number before now. If we take fifty mares each to be the number put to these five horses, that will give a sum of 8,500 guineas for the season, and this is the more extraordinary when it is taken into account that the oldest of these five stallions was only foaled in 1849; it is too soon yet to look back to Pocahontas, with all the multiplied advantages that her produce will represent ten or twenty years hence. We know of no other mare that has produced such a number of young stallions to begin with.

Comparisons, however are not the means by which we seek to deduce important conclusions from this notice: we could adduce an indefinite number of instances where the highest class blood mare has added to the wealth of a rich man, and not a few in which the useful mare, well managed, has greatly improved the condition and status of the farmer, all going to prove that the English horse-breeder should act like the Arab over his mare, when he really possesses a good one: by no means lightly part with her, as the opportunity does not occur very often, even when judgment and money are available, to find good brood mares of any distinct class; besides, we do not know what they will prove to

be until tried. Hence the increased value of a tried good stallion over an untried one, and of the mare whose produce has proved winners, or realized high prices in the market, over that of a casualty one.—*Edinburgh Veterinary Review.*

### Mortality amongst Ewes.

In the earlier districts of England and the South of Scotland, the lambing has generally progressed very favourably; a large crop of lambs is reported, and in some flocks an unusual predomance of twins is spoken of. One gentleman is surprised by beginning a prolific season with 17 lots of twins, and a triplet. The abundance of keep has told favourably on the condition both of the ewe and lamb, and neither mother nor offspring have yet suffered materially from the provoking continuance of the unexampled wet. But to some farmers the wealth of winter keep has not been altogether for good, and we learn that the ewes in some quarters have been ailing several weeks before lambing, and dying apparently from some fulness of blood." We have recently heard of several such cases occurring on some of the rich lands of the midland counties of England, and append an interesting letter from a correspondent who has suffered, in the same way near the good old city of York:—

In this neighbourhood the mortality among our flocks of breeding ewes is unusually great, but what has induced the sickness which in so many cases proves fatal seems difficult to ascertain. Owing to the turnip crop being remarkably good, ewes have never been better kept; by far the greater number of them having been eating turnips on the arable land, *ad libitum*, and are therefore in as good condition as can be desired. We generally remove them to the grass fields two or three weeks before lambing, and give swedes with a moderate allowance of oats to produce a good flow of milk, and it is at this critical period that disease of a fatal kind has made its appearance. The first symptoms are—giddiness somewhat resembling the sturdy, a staggering gait, followed by dulness, refusal of food, and a complete prostration of strength, so that if the animals are compelled to rise on their legs, they walk feebly for a few steps, and lie down as soon as possible. It is certainly strange that young fresh ewes in good condition should succumb to disease before lambing, especially as the pastures are in a very forward state for the season of the year. We might be led to conclude the cause had been in operation for a considerable time. A few years ago my next neighbour's ewes were similarly affected. If they were roused up when laid down they stared wildly about, staggered backward and fell: as might be expected they lambed without milk, and died along with their sickly offspring.

I must not omit to state that the weather during the last three weeks has been very wet, so that the ground is thoroughly saturated. Will you be kind enough to inform me in your next week's paper what system of management may at once be adopted, and how the sickly ewes should be treated after disease has shown itself.

The excellence of the winter keep, the early luxuriance of the grass, and the liberal extra feeding, have, doubtless, conspired to produce a condition of plethora, in which the symptoms described appear to depend. We last summer met with several cases amongst cows of a character very analogous to those described by our correspondent. The animals were four and five years old, in high condition, and fed on clover, with vetches and some bean flour given at night when the cattle were driven into a yard. Three weeks or a month before calving they became restless and stupid, neglected their food, were feverish and unsteady on their legs, and several died rather suddenly and after only a day's illness. But it is certainly seldom that such overfulness of blood does harm either to cows or ewes before parturition. After that event, however, it frequently causes much mischief, producing especially the apoplectic and very fatal form of puerperal fever. Within a month or six weeks after lambing, when the thriving lambs begin to get strong, and the spring grass is fresh and plentiful, the milk is apt to become so rich and abundant that the lambs appear to thrive too rapidly, take diarrhoea, and die in numbers. Many rich grass lands are on this account unsuitable for ewes and young lambs.

To arrest the disorder will possibly be found somewhat difficult. The grass fields selected for the ewes, when they are removed from the turnips, should be as dry as it is possible to find in this wet season; whilst the herbage ought not to be too luxuriant. It will conduce to health if they have to roam a little for their food. The Swedes should be given only in moderate amount, and the oats may be discontinued until after lambing. With the excellent condition of the ewes, there is little fear of shortness of milk. If afterwards found deficient, a little oilcake mixed with bran will be useful, and is preferable to the oats, which sometimes produce, in sheep unaccustomed to them, disordered stomach and constipation. Salt should be provided in covered troughs, and a little nitre, which may be conveniently given mixed with bran, will also be advisable, care being taken that individual sheep do not take more than their own share. An ounce will suffice for eight sheep, and the medicated mash may be safely enough continued for a week or ten days without much risk of its acting unduly on the kidneys.

The treatment of the disease when once developed will prove, we fear, rather unsatisfactory, for sheep always make indifferent patients, and ewes heavy in lamb are especially difficult to

doctor, and can stand neither much medicine nor any rough handling. Purgative medicine, with a laxative diet, and an occasional dose of nitre will constitute the appropriate remedies. A moderate and early bleeding may also be advisable, but will have the serious disadvantage of being apt to bring on parturition. For both prevention and cure the great matter is to keep up if possible the action of the several excretory channels—the bowels, the skin, and the kidneys, and to promote a healthy state of the body by moderate and judicious feeding.—*The Veterinarian*.

## Miscellaneous.

### Curious Phenomenon.

"How is it that you raise such large and nice onions?" I asked of an Iowa farmer, as I was sitting at table with him, and observing some on the table.

"Well," said he, "we sprout the seed with boiling water, and then plant it early and in good ground."

"Sprout the seed in boiling water?" I exclaimed, inquiringly. "What do you mean, sir, by that? Won't boiling water kill the seed?"

"Not at all," he replied; "but it will sprout them, in one minute's time."

"It will? It looks incredible," I replied with surprise.

"Well, you try it," he replied, "when the time comes to plant, and you'll find it just as I tell you."

And sure enough, when spring came, and my neighbour was planting his onion seed, being present, I said:

"Jewell, last winter there was a man in Iowa told me that to pour boiling water on black onion seed would sprout it in one minute. Suppose you try it?"

"Very well," said he. And taking the tea-kettle from the stove, he poured the boiling water on the seed, which he had in a saucer. Looking closely at it for a moment, exclaimed, "You have told rightly. Only look there."

I looked, and behold, the little sprouts about as large as horse hairs were shooting out of the opened ends of the seeds! He did not retain the water on the seed above three seconds, and in less than one-half minute after it was poured off, the sprouts were projecting from the seeds.

My Iowa friend assured me that this process would advance the growth of the onion two or three weeks beyond the ordinary method of planting without sprouting.—*New England Farmer*.

**PARRAFINE.**—How wonderful to trace the circulation of matter in nature, even in such an apparently simple thing as a burning candle!

Parrafine has existed in other forms for millions of years, perchance in the rain and the atmosphere which fostered the tree and the shrub, and the tender flower, flourishing in worlds now passed away. Vegetation seemed to perish, and leave no trace behind; but nature, ever working, was storing the relics, to accumulate them in the exhaustless coal beds, destined to illumine the inhabitants of the worlds to be. And now, as the taper grows smaller and smaller, who can tell what part those products of its combustion will have to play in the economy of the universe? They are not lost, but will enter once more into the foliage of the future, as the same products entered into the dim, mysterious past. Thus by an eternal round, parrafine may produce parrafine, as a grain of wheat produces a grain of wheat.—*Mechanic's Magazine*.

**THE DEEPEST "DUG" WELL IN THE WORLD.**—A clever lecture by Mr. Henry Catt, tells us that the Warren Farm well is not an artesian, having been dug, not bored. The scientific facts he says, learned from this great work are—that the upper green sand has no existence in this locality; that the gault is double its usual thickness; that Mr. Martin, of Pulborough, is right in saying that gault should be classed with chalk and, lastly, that digging is better than boring a well. The upper chalk extends 418 ft.; the grey marl, 155 ft.; blue marl, 173 ft.; firestone, 8 ft.; gault, 282 ft.; ditto, with green sand, 25 ft.; clay, 5 ft.; green sand, 5 ft., ferruginous beneath; from which we may deduct 10 per cent for the dip. In the strata pierced fossil oysters and ordinary gault fossils were found; also fossil wood perforated by the toredo, in some cases having the cavities filled with bisulphate of Iron. He believed the water came from Ditching Common. Mr. Hollis said that the artesian wells at the County Lunatic Asylum, at Hayward's Heath, was nearly 900 feet deep, and its supply derived from the ferruginous strata. The water was very wholesome, and the supply so abundant that, after they had pumped out 40,000 gallons, it hardly lowered the level one inch.—*Sussex Express, England*.

**THE ALPACA WOOL.**—The shearing of the alpacas which was in process at the time we published our last summary, has recently been completed, and we are happy to state that the result is considered very satisfactory. The number of animals shorn was 306, and the total amount produced was 24 cwt., making an average of 8½ lb per fleece. Besides the above the flock includes a number of last years lambs; none of these were shorn, their fleece being too short. By far the large portion of the wool was obtained from animals born in the colony, and the fleeces are consequently those of Australian alpacas, this being the first regular shearing that has taken place. The sample is pronounced a very fine one; and a great improve-

ment upon the former clip. The wool will shortly be shipped, and it will be a matter of interest to learn how much the first large parcel of Australian alpaca will realize in the English market.—*Sydney Morning Herald* Feb. 19, '62.

**THE POET LAUREATE AND THE LATE PRINCE CONSORT.**—It is stated that Mr. Alfred Tennyson has received from the Princess Alice a most touching autograph letter, written by command of her Majesty, expressing the intense pleasure and consolation which the Queen has derived from the dedication prefixed by the Laureate to the new edition of his "Idylls of the King"—a work which was an especial favourite with the late Prince Consort. The following is the dedication referred to:—

"These to his memory,—since he held them dear,  
"Perchance as finding there unconsciously  
"Some image of himself—I dedicate,  
"I dedicate, I consecrate with tears—  
"These Idylls.

"And indeed he seems to me  
"Scarce other than my own ideal knight,  
"Who revered his conscience as his king;  
"Whose glory was redressing human wrong;  
"Who spake no slander, no, nor listened to it;  
"Who loved one only, and who claved to her—  
"Her—over all whose realms to their last isle,  
"Commingled with the gloom of imminent war,  
"The shadow of his loss moved like eclipse,  
"Darkening the world. We have lost him; he is gone;  
"We know him now; all narrow jealousies  
"Are silent; and we see him as he moved,  
"How modest, kindly, all accomplish'd, wise,  
"With what sublime repression of himself.  
"And in what limits, and how tenderly;  
"Not swaying to this faction or to that;  
"Not making his high place the lawless perch  
"Of wing'd ambitions, nor a vantage-ground  
"For pleasure; but thro' all this tract of years  
"Wearing the white flower of a blameless life.  
"Before a thousand peering littlenesses,  
"In that fierce light which beats upon a throne,  
"And blackens every blot: for where is he,  
"Who dares foreshadow for an only son  
"A lovelier life, a more unstain'd than his?  
"Or how should England dreaming of his sons  
"Hope more for these than some inheritance  
"Of such a life, a heart, a mind as thine,  
"Thou noble Father of her Kings to be,  
"Laborious for her people and her poor—  
"Voice in the rich dawn of an ampler day—  
"Far-sighted summoner of war and waste  
"To fruitful strifes and rivalries of peace—  
"Sweet nature gilded by the gracious gleam  
"Of letters, dear to Science, dear to Art,  
"Dear to thy land and ours, a Prince indeed,  
"Beyond all titles, and a household name,  
"Hereafter, through all times, Albert the Good.

"Break not, O woman's heart, but still endure;  
"Break not, for thou art Royal, but endure,  
"Remembering all the beauty of that star  
"Which shone so close beside thee, that ye made  
"One light together, but has past and left  
"The crown a lonely splendour.

"May all love,  
"His love, unseen but felt, o'ershadow thee;  
"The love of all thy sons encompass thee,  
"The love of all thy daughters cherish thee,  
"The love of all thy people comfort thee,  
"Till God's love set thee at his side again."

**OLD CUSTOMS IN CONNECTION WITH THE APPLE TREE.**—In Sussex, England, the blessing of the apple tree is still observed. On the eve of Christmas day, young and old people assemble in the orchard and commence dancing round a large apple tree, repeating a rude chant to words

of this purpose:—"God bless this tree to the use of the master. May it flourish and bring forth abundantly, even to fill a hat, to fill a basket, to fill a cart, to fill a waggon." The same ceremony is performed round every apple tree and pear tree in the orchard. In Devonshire, a certain apple tree, as a representative of the rest, is sprinkled with cider, or a bowl of it is dashed against the tree, or cakes steeped in cider are hung upon the branches, followed by an incantation, and a dance round the tree, and then home to feast.

**BE CHEERFUL AT YOUR MEALS.**—The benefit derived from food taken, depends very much upon the body while eating. If taken in moody, cross or d spairing condition of the mind, digestion is much less perfect and slower, than when taken with a cheerful disposition. The very rapid silent manner too common among Americans, should be avoided, and some topic of interest introduced at meals, that all may partake in, and if a hearty laugh is occasio nly indulged in, it will be all the better. It is not uncommon, that a person dining in pleasant and social company, can eat and digest well that which when eaten alone, and the mind absorbed in some deep study or brooding over cares and disappointments, would lie long undigested in the stomach, causing disarrangement and pain, and if much indulged in, become the cause of permanent and irreparable injury to the system.

**HOW TO TEACH A PARROT TO TALK.**—In order to teach a parrot to imitate sounds, the best and the simplest mode is to take the bird into a perfectly quiet room, where it can hear and see no one but the instructor, and will not have its attention distracted by surrounding objects. Then, after taking every care to render the feathered pet familiar, speak the words, or produce the sounds, which the bird is required to imitate, and be careful to avoid varying them even by the fraction of a tone. You will soon see the pupil taking notice of the oft-repeated sound, and it will presently hold its head aside, as if to catch the tones more clearly. After a while it will try to imitate them; and as soon as it makes an attempt, however imperfect, make much of the bird, and give it a small morsel of some special dainty.—*Every Boy's Magazine*.

**INGREDIENTS OF WHEAT.**—Estimating the yield of wheat at 25 bushels, 60lbs. the bushel, the amount 1,500lbs. carries off 30lbs. of ash; the straw, estimated at 3,000lbs., taking off 180lbs. The 210lbs. of ash carried off per acre by a crop of wheat as above is made up as follows: Potash 25.59lbs., soda 3.02, lime 12.94, magnesia 10.52, oxide of iron 2.55, phosphoric acid 20.56, sulphuric acid 10.56, chlorine 1.97, silica 118.29. In wheat the proportion of grain is 29 per cent., of straw 71.

**HOW TO CURE KICKING HORSES AND RUNAWAYS.**—The experiments of Rarey, the Horse Tamer, and the promulgation of his theory of horse training and management, are bringing before the public much useful knowledge upon this interesting subject. Whatever may help to bring the horse, especially vicious horses, as they are called, more completely under the subjection of man without the necessity of resorting to cruel treatment, ought to be known by all who have the management of equine quadrupeds. We heard a day or two since, a description of the taming of a kicking horse and another who was an inveterate runaway, by methods so simple and Rareyish that we cannot forbear to publish them for the benefit of horseologists in general.

If you have a horse that has a habit, when in harness, of bringing his heels in contact with the dasher and damaging the vehicle by kicking, proceed as follows:

Place around his neck a band like that used for the riding martingale. Then take two light straps, buckle them to the bit on either side, pass them through the neck band and thence inside the girth and strap them securely to each fetlock of the hind feet, taking care to have them of the proper length. When a horse is rigged in this manner if he attempts to "kick up behind," each effort will jerk his head down in such a way as to astonish him, and perhaps throw him, over his head. He will make but a few attempts to kick when he finds his head thus tied to his heels, and two or three lessons will cure him altogether.

The method of reforming a runaway is equally simple and effectual. First of all, fasten some thick pads upon your horse's knees, then buckle a strap, about the size of a rein, upon each fetlock forward, and pass the straps through the hame rings or some part of harness near the shoulder on each side and lead the straps back to the driver's hand as he sits in the buggy. He has thus four reins in hand. Start the animal without fear; don't worry him with a strong pull upon the bit, but talk to him friendly.—When he attempts to run he must of course bend his forward legs. Now pull sharply one of the foot reins, and the effect will be to raise one of his forward feet to his shoulders. He is a three-legged horse now, and when he has gone on in that way a little distance drop the constrained foot and jerk up the other. He can't run faster on three legs than you can ride, and when you have tired him on both sides pretty thoroughly, or if he refuse to take to his trot kindly and to obey your voice and a moderate pull on the bit, you can raise his fore feet, drop him upon his knees, and let him make a few bounds in that position. The animal will soon find that he can't run away; that he is completely in your power, and by soothing words you will also be able to convince him that you are his friend.—He will soon obey your commands, and will be

afraid to extend himself for a run. Within a week or two some horses that were quite valuable animals in respect to everything but their bad habits of kicking and running in harness, were cured by methods described above. The experiments are such as can be made by any person at all accustomed to managing horses, and we hope it may prove serviceable to some of our readers.—*Boston Herald.*

**EDUCATED FEET**—Who can tell to what uses the feet and toes could be put, if a necessity arose for a full development of their powers? There is a way of educating the foot, as well as the hand and the eye; and it is astonishing what an educated foot can be made to do. We know that in the time of Alexander, the Indians were taught to draw their bows with their feet, as well as with their hands, and Sir J. E. Tennent tells us that this is done up to the present time by the Rock Veddahs, of Ceylon. And nearly all the savage tribes can turn their toes not only to good, but bad account; like the aboriginals of Australia, who, while they are cunningly diverting your attention with their hands, are busily engaged in committing robberies with their toes, with which they pick up articles as an elephant would with his trunk. So also the Hindoo makes his toes work at the loom, and weaves with them with almost as much dexterity as with his fingers. The Chinese carpenter will hold the bit of wood he is planing by his foot, like a parrot, and will work a grind-stone with his feet. The Banaka tribe, who are the famous canoe-men on the West African coast, will impel their light canoes—weighing only from eight to ten pounds—with great velocity over the waves, and, at the same time, will use the foot to bail out water; and when they would rest their arms, one leg is thrown out on either side of the canoe, and it is propelled with the feet almost as fast as with a paddle. There was also Monsieur Ducornet, who died only four years ago, who, although he was born without hands, was brought up as an artist and who annually exhibited at the Louvre pictures painted by his feet. Then there was Thomas Roberts the armless huntsman to Sir George Barlow whose feet were made to perform the duties of his hands. And there was William Kingstone, who with his toes wrote out his accounts, shaved and dressed himself, saddled and bridled his horse, threw sledge hammers, and fought a stout battle, in which he came off victorious.—*Cuthbert Bede's Glencreggan.*

**PAY OF ARCHITECTS IN THE 17TH CENTURY.**—Long before Brindley's time Inigo Jones was paid only eight shillings and fourpence a day as architect and surveyor of the Whitehall Banqueting House, and forty-six pounds a year for house-rent, clerks, and incidental expenses; whilst Nicholas Stowe, the master mason, was allowed but four and tenpence a-day. When

the Duchess of Marlborough was afterwards engaged in resisting the claims of one of her Blenheim surveyors, she told him indignantly "That Sir Christopher Wren, while employed upon St. Paul's was content to be dragged up to the top of the building three times a-week, in a basket, at the great hazard of his life, for only £200 a-year"—the actual amount of his salary as architect of that magnificent cathedral. Brindley, however, fared worse still, and for a long time does not seem to have risen above mere mechanics' pay, even whilst engaged in constructing the celebrated canal for the Duke of Bridgewater, which laid the foundation of so many gigantic fortunes.—*Smiles' Engineers.*

**DOCTORS' EMOLUMENTS.**—Of the slow promotion in medical ranks, even in the case of the most skilful and deserving, the earnings of Sir Astley Cooper afford a striking example. In the first year he netted five guineas; in the second twenty six pounds; in the third, sixty-four pounds; in the fourth, ninety-six pounds; in the fifth, a hundred pounds; in the sixth, two hundred pounds; in the seventh, four hundred pounds; in the eighth, six hundred and ten pounds; and in the ninth, the year in which he secured his hospital appointment, eleven hundred pounds. The highest amount he ever received in any one year was £21,000; but for many years his average income was over £15,000.

**COLOURS OF ICEBERGS.**—We are off on the gentle rollers of the bay of St. Louis, after a low, broad iceberg, covering say an acre of surface, and grounded in forty fathoms of water. It has upon one extremity a bulky tower of sixty feet, on the other forty, and in the middle a huge pile of ice-blocks of all shapes and sizes, the ruins of some spire. While the outside of this heap of fragments is white with tints of green, touch hear and there with the most delicate bronze and gilding, every crevice where there is a shadow lurking is a blue, the purity and softness of which cannot be described, nor easily imagined. To one who has any feeling for colour, it has a sentiment as sweet as anything in nature. A pure white surface like this fine opaque ice, seen through deep shade, produces blue; and such a blue as one sees in the stainless sky when it is full of warmth and light. It is quite beyond the rarest ultramarine of the painter. The lovely azure appears to pervade and fill the hollows like so much visible atmosphere or smoke. One almost looks to see it float on the crystal cells where it reposes, and thin away into colourless air.—*After Icebergs with a Painter.*

**COSTUME.**—Trousers may have many advantages: they are dusty at the feet in summer, and muddy in winter. They get easily out of shape and baggy at the knees, and much overheats the lower parts of the body, and thus, to some extent, demoralize the individual; while

the practice of wearing unwashable trousers next the skin for six months is a dirty habit. True, if drawers are worn, his inconvenience is avoided; but perhaps impede free motion, press upon the stomach, and drag inconveniently at the braces. The present practice of turned down collars must be a great comfort to those who formerly wore tight cravats and stiff collars; but the student and the cricketer alike throw off the collar and the necktie when much work is to be done; and it seems to me that, for health and elegance, the neck should be as free as possible, and that a narrow shirt-band, fastened with an ornamental button, might be a good substitute for the "turn-downs." Indeed, the turned collars of shirts, coats and waistcoats, form lines which do not harmonize with the square lines of the male figure, and they diminish the apparent width of the shoulders. Beards are natural to man, and it is a violation of nature to use the daily razor; but, at the same time, beards are too natural to harmonize with modern dress. If a committee were formed, consisting of men of taste—sportsmen, artists, soldiers, and physicians—assisted by the practical knowledge of manufacturers and tailors, a costume might be devised at once graceful, comfortable, and economical; and I do not see why, at the forthcoming Great Exhibition, the best manner of clothing the human body should not be thoughtfully considered.—*Dr. Wild, in Builder.*

**STRANGE HABIT OF PARROTS.**—When domesticated, the parrots, macaws, parakeets, and cockatoos show the same partiality for vegetable seeds, and are generally fed very well on hempseed, the skins or husks of which they detach with astonishing skill. Some that receive bones to gnaw acquire a very determined taste for animal substances, and especially for the tendons, ligaments and other less succulent parts. From this kind of feeding, some parrots contract the habit of plucking out their own feathers, that they may suck the stems; and this becomes urgent a want that instances have been known of their stripping their bodies absolutely naked, not leaving a vestige of down wherever the bill could reach. They spared, however, the quills of the wings and tail, the plucking out which would have caused too much pain. M. Dumarest states that the body of one of these birds, belonging to M. Latreille, thus became as a pullet plucked for roasting. Yet the bird supported the vigour of two very severe winters without the slightest alteration of health or appetite. M. Veillot observes that this habit of depilation is produced in many parrots by an itching of the skin, and not in consequence of their being accustomed to eat animal substances.—*Cassell's Natural History.*

**A SUPERSTITION ABOUT THE ASH TREE.**—In the Highlands of Scotland, at the birth of a child, it is said that the nurse takes a branch of

the ash-tree, one end of which she puts into the fire, and, while it is burning, receive into a spoon the sap which oozes from the other end: this she gives to the child to be mingled with its first food. It is supposed to impart wonderful virtue. In King's County, Ireland, near Kenery Church, is a famous ash, the trunk of which is now 21 feet 10 inches in circumference. When a funeral of one of the peasantry passes by this tree, the procession pauses, the body is laid down for a few minutes, while all offer a few words of prayer. Then each person casts a stone to increase the heap which has been accumulated over its roots. This is imagined to benefit both the dead and the living. There is an ancient saying, that "a serpent would rather creep into the fire than over a twig of an ash-tree." Cowley, enumerating various prodigies, says :

"On the wild ash's top, with bats and owls,  
With, all night, ominous and baleful fowls,  
Sate brooding, while the screeching of the doves  
Profaned and violated all the groves."

It is surprising how many of such follies will creep into men's minds.—*The Druggist*.

**AN AGRICULTURAL PASTIME.**—The season has begun for holding jubilees of the Sparrow Clubs, and scarcely a week now will pass on which we shall not be called upon to record the celebration of one or more of these village festivals. We shall be requested to chronicle how Farmer Giles took the chair; Labourer Hodge, the vice; how mine host of the "Toad under the Harrow" supplied a supper in his usual splendid style, utterly regardless of cost; how old Job Lynxeye, tenant farmer, and young Abel Anvil, blacksmith, produced so many thousand heads of small birds, and triumphantly carried off certain sweepstakes provided for the victors; how the night was spent in mellifluous harmony; how the patriotic aviscides passed a most agreeable night, and how they did "not go home till morning." Now, we have serious doubts whether these bird slayers do not do a great deal more harm than good; and we really should be greatly obliged if some experienced person, capable of forming a correct opinion on the matter, would direct his attention to it, and favour us with the result of his inquiries. Our own decided impression is, that it is mischievous folly to destroy indiscriminately all small birds; but we should much like to be favoured with really sound practical information on the subject. Hitherto, our French neighbours have been the most inveterate of bird destroyers. The result has been so enormous an increase of those reptiles and insects which prey upon the crops of grain and other vegetable food, and so deficient a harvest, that we should not be surprised if the French Government were to resort to stringent measures to prevent this wholesale slaughter. Let us state two facts for the con-

sideration of our rural readers, and there we shall leave the matter for the present. The cockchafer deposits from 70 to 100 eggs, which are soon transformed into white grubs, which live on the roots of our most valuable vegetables. The weevil lays from 70 to 90 eggs, which, laid in so many grains of corn, become larvae, and soon eat up the corn. Now swallows, hedge-sparrows, and other small birds live principally upon grubs, caterpillars, and other insects and animalcules which prey on and destroy the products of agriculture. Ten swallows were recently dissected, and in their stomachs were found the remains of 5,482 insects, which must have been the results of a few hours' feeding. We trust that our farmers will be induced to think over this matter, and will not join in unreasoning crusades against sparrows and water-wagtails, on account of the supper at the "Toad under the Harrow," and the conviviality of the guests over the dead bodies of larks, wrens, finches, whitethroats, and others of the feathered songsters, whose notes, for purity, richness, melody, and variety, we will back against the boisterous glee of all the bacchanals who ever assembled at the "Toad under the Harrow" aforesaid.—*West Surrey Times*.

**THE LONDON SHOEBLACKS AND THEIR EARNINGS.**—The shoeblacks who stud the broadways of London, in their cheerful jersey's, yellow, red, and blue, have shown the possibility of turning out well. Nine years have elapsed since this branch of labour was introduced: and these boys, it is said, have earned about £12,000. Their united earnings for the last financial year amounted to £4,548, representing the blacking and polishing of no less than 1,119,320 pairs of boots.

**A SHYING HORSE.**—Nine out of every ten horsemen start in their seat whenever a horse shies, and then the horse is either by whip or spur driven up to the object. This makes horses look at any singular object, with more nervousness, for they expect a thrashing at the same moment. The rider should neither shy himself, nor notice it in his horse; and far less punish him.

**A VALUABLE DISCOVERY.**—Professor J. B. Turner says, that through a succession of experiments upon himself, his children, his horses, and other cases, he has discovered that Coal Oil is a certain and speedy remedy for scrofulous eruptions, and all kinds of local diseases, such as rheumatism, pains in the side, shoulders, back and joints, croup, sore throat, bruises, strains, cuts, and lacerations of all sorts on men and animals. He mentions several cases in his own family, where the application of this oil gave instant and permanent relief, and finding its effects so beneficial, he has thought proper to make the discovery known to the public.

## Editorial Notices, &c.

**SUBSCRIPTIONS TO AGRICULTURIST.**—We have to thank the officers of Agricultural Societies, and other correspondents, who act as agents for the *Agriculturist*, for their continued activity in obtaining subscriptions. The following statement, which was intended to have been published long ago, shows the prizes awarded for the 20 highest paid subscription lists to April 1st, 1861. Several correspondents who did not obtain prizes, would have been entitled to them if they had been sufficiently prompt in their orders and remittances:

## Seeds! Seeds!! Seeds!!!

**JACOB GEORGE WAITE**  
181 High Holborn, London, England.

**HAS THE LARGEST STOCK** of VEGETABLE, AGRICULTURAL, and FLOWER-SEEDS, IN THE WORLD, and can supply dealers on better terms than any other whose sale house, as he makes most extensive arrangements with none but experienced growers do produce his supply of seeds, which are raised and grown from stock selected under his own personal superintendence, and as they are all cleaned and picked in his own extensive warehouses by an auxiliary strength of several hundred men and women, kept for that purpose, he is enabled to recommend, with the greatest confidence, every description of Seed offered by him for sale, and he therefore invites Seed Dealers to apply for his Catalogue.

**TERMS**—Cash, or satisfactory reference in England.

March, 1862.

6t.

## THOROUGH BRED STOCK FOR SALE.

**THE SUBSCRIBER** has for Sale Durham and Galloway Cattle, male and female. Leicester, Cotswold, Lincolnshire, Down and Cheviot Sheep; Cumberland and Yorkshire improved Pigs. All imported stock.

GEORGE MILLER.

Markham, June 3rd, 1862.

6t.

## FOR SALE.

**A LOT** of thorough bred improved Berkshire Pigs of various ages.

R. L. DENISON,

Dover Court.

Toronto, Aug., 1861.

## Notice of Partnership.

**THE** Undersigned have entered into Partnership as Seedsmen and dealers in all kinds of Agricultural and Horticultural Implements, under the firm of James Fleming & Co.

JAMES FLEMING,  
GEORGE W. BUCKLAND.

## NOTICE.

**JAMES FLEMING & CO.,** Seedsmen to the Agricultural Association of Upper Canada will carry on the above business, wholesale and Retail, at 126 Yonge-st., 4 doors North of Adelaide-street, until next July, when they will remove to the new Agricultural Hall, at the corner of Queen and Yonge-streets.

**JAMES FLEMING** will continue the business of Retail Seedsmen and Florist at his old stand, 350 Yonge-street.

Toronto, January 1st, 1861.

## IMPROVED BERKSHIRE PIGS

**FOR SALE** by Mr. Denison, Dover Court, Toronto.

Toronto, April, 1862.

## A Thorough Bred 2 Year Old

## AYRSHIRE BULL

**FOR SALE**, by Mr. Denison, Dover Court Toronto.

April, 1862.

## VETERINARY SURGEON.

ANDREW SMITH, Licentiate of the Edinburgh Veterinary College, and by appointment, Veterinary Surgeon to the Board of Agriculture of Upper Canada, respectfully announces that he has obtained those stables and part of the premises heretofore occupied by John Worthington, Esq., situated corner of Bay and Temperance streets, and which are being fitted up as a *Veterinary Infirmary*.

Medicines for Horses and Cattle always on hand. Horses examined as to soundness, &c.

Veterinary Establishment, Corner of Bay and Temperance Sts.

Toronto, January 22nd, 1862.

THE  
JOURNAL OF THE BOARD OF ARTS  
AND MANUFACTURES,  
FOR UPPER CANADA,

Is Published on the first of every Month,

At \$1 per annum for single copies, or to clubs of ten or more at 75 cents. per copy; to members of Mechanics' Institutes, and of Literary, Scientific, and Agricultural Societies, through their Secretary or other officer, 50 cents per annum per copy.

Subscriptions payable in advance.

Printed for the Board of Arts and Manufactures for Upper Canada, by W. C. CHEWETT & Co., King Street East, Toronto.

## The Agriculturist,

OR JOURNAL AND TRANSACTIONS OF THE BOARD  
OF AGRICULTURE OF UPPER CANADA,

IS published in Toronto on the 1st and 16th of each month.

Subscription—Half a dollar per annum for single copies; Eleven copies for Five Dollars Twenty-two copies for Ten Dollars, &c.

Editors—Professor Buckland, of University College, Toronto, and Hugh C. Thomson, Secretary of the Board of Agriculture, Toronto, to whom all orders and remittances are to be addressed.

### The Wheat Crop and its Enemies.

The wheat crop this year has not only had, in common with the other products of the farm, to contend with an unusually backward and dry season, which under any circumstances would render a rather light crop almost inevitable, but it has also yet to run the gauntlet of its numerous insect enemies. The wheat midge has been observed in various parts of the country in large numbers, either in the larva or in the perfect fly state, and unless some peculiar favoring circumstance should intervene, it is highly probable that the injury from this cause will be very considerable.

A few days ago, namely on the 20th of June, Mr. Charles Shaver, who resides on Dundas Street, in Etobicoke township, near Islington Village, brought us in some specimens of the larvæ of the Wheat Midge, which he had found in immense numbers on the surface of the ground in fields where he had wheat last year, and which are now in fallow, Indian Corn, potatoes, or other spring crop. His neighbours had found the larvæ in similar situations and similar quantities, but always only in fields which had been under wheat last year. Having been informed only about a week previously by a gentleman residing near the same locality, that he had already seen the matured fly in immense swarms hovering over the wheat fields this season, and not recollecting at the time of having ever heard of the larvæ having been seen in such enormous

numbers in the ground in the manner described by Mr. Shaver at this season of the year, we were at first inclined to suppose that the larvæ found by him and his neighbours must be the produce of eggs laid by the perfect fly this season, although it was a puzzling question how they could have got into the situations in which they were found.

On further consideration, however, and after consulting works written on the subject, we arrived at the conclusion that these larvæ were the same that had been left upon the wheat fields after harvest last year, and that they had remained there ever since, till awakened into activity by the warm rains which fell about the 18th or 19th, when they had worked their way to the surface. The Secretary of the Board of Agriculture was induced to address a note to one of the city newspapers embodying this view, and asking the attention of farmers to the subject. He has received several communications in reference to this letter, which make it quite evident that his view was the correct one. In fact there could be no doubt about it when the habits of the insect are studied. The circumstance of the perfect fly having been seen in great multitudes in one locality as early as about the 12th or 15th of the month, of the truth of which statement we are quite assured, and the same insect, but still progressed no further than the larva state, being seen a week afterwards in the ground, in such immense numbers, in another locality only a few miles distant, must we

think be accounted for by some local peculiarity of the soil or weather.

The insects found by Mr. Shaver doubtless remained quiescent in their earthy bed somewhat later than usual, in consequence of the long continued drought, and the comparatively cool weather, till, on the rain moistening the ground, they suddenly came up to the surface in such large numbers as to be conspicuously visible. Mr. Shaver first observed them while examining the progress of his field of Indian Corn.

Where the Secretary of the Board appears to have been in error, however, in his letter addressed to the newspapers, was in the time allowed for the insect to get into the winged state, after being seen on the ground in an active larva state. We had formed the impression that the larvæ in spring or early summer would be found in the pupa or chrysalis state, but they appear to come up to the surface as active maggots, and in a very few days afterwards, probably about a week, to be transformed into perfect winged flies, when, or very soon afterwards they commence their operations upon the growing grains.

An esteemed correspondent from the neighbourhood of Cobourg, informs us that he has frequently in the beginning of summer, after a rainy day, found the larvæ of the wheat fly in countless numbers on the surface of his fields where there had been wheat the previous year, and that on placing some of them in a glass they would become flies in about a week. Mr. Shaver, a week after he had brought in the specimens already mentioned, writes that—"The larvæ have nearly all disappeared. There are a few still remaining, but very few. I collected a few the day after I saw you and put them in a glass, but the earth got so dry they could not live. There are a few still in the ground, very near the surface. With another shower of rain they would come through. For two or three days back there are numbers of the midge flying through the wheat, but is too soon to detect the amount of injury done."

We have given some attention to this subject, not because there are any new facts disclosed, but because observations made under peculiar circumstances of season, &c., brought them into prominent notice. It is important that farmers

should become thoroughly conversant with the habits of an insect which is capable of doing such enormous damage to our most important field crop, for they will thereby be better enabled to guard against its ravages.

A writer in this journal two or three years ago suggested that where the wheat midge has infested a crop, the field should be deeply trenched in autumn, covering up the surface entirely out of sight, and that it should be left in that condition, without ploughing again, for an entire year, that thereby the larvæ should be smothered and never able to reach the surface again. Were it possible to induce every farmer in a section of the country to adopt such a plan, perhaps the evil might be to a great extent removed. It is not probable that the insect would be able to rise to the surface through any great depth of soil. The suggestion may be worthy of consideration by those who are most deeply interested. Due attention, however, to well recognized remedies may secure partial exemption: Take care to destroy such of the larvæ as come into the barn, and are blown out with the chaff on cleaning the wheat. Sow fall wheat early, and of an early ripening kind, on well drained and well prepared soil, so that it may escape winter killing and come into ear early enough in spring to escape damage. For spring wheat choose an early ripening kind and sow late, so that it may come into ear after the fly has disappeared.

This year, another insect pest threatens to infest the wheat crop in this part of the country but fortunately, in this case, although the creature is from its numbers of sufficiently formidable appearance, we believe it is not likely to inflict any very serious injury. Mr. Shaver, already mentioned in this article, has brought us in several ears of wheat in which are found a pretty large number of the grain aphid. A notice of this parasite was given in the *Agriculturist* of August 16th, last year. It appeared in the eastern part of Upper Canada last year in such large numbers in some cases as to give the ears of wheat a brownish appearance, but did not seem to injure the crop much. These aphides are found in the crevices between the different lobes of the wheat ear. They are from a dark brown to a grass green in color, and are

very similar in appearance to the common plant louse, often found on some garden and greenhouse plants. They increase with incredible rapidity. We shall be glad to hear from any of our readers who may make any observations upon the movements or progress of this new wheat parasite.

### Remedy for the Turnip Fly.

Mr. E. G. O'Brien of Shanty Bay, near Barrie, informs us that he has for several years used the following prescription to prevent the ravages of the turnip fly, and on each occasion the plant has escaped injury, an exemption which he imputes the effects of the preparation: Oil of turpentine, one teaspoonful to 1 lb of seed, stirred till the oil is absorbed, and the seed held between the eye and the light will have a shining, glistening appearance. The seed should then be immediately sown. Several of Mr. O'Brien's neighbors have used the same remedy and always with the same successful result, which they attribute to the odour or some other property of the oil. It is the oil, not the spirits of turpentine, which is used, and which may be got of any druggist. The writer of this paragraph has on several occasions used fish oil in a similar way, and always with favourable results, but whether the safety of the plant was due to the prescription, or to some other favoring circumstance, he could not feel very confident.

### The Season and the Crops.

We have passed through the last three or four months, a period of extraordinary weather. The large quantity of snow that fell during winter went off with little or no rain. Spring opened late, with occasionally a very low temperature, and somewhat severe frost has now and then occurred up to the middle of June. May was the driest month experienced here for many years. A severe drought has consequently been spread over the greater portion of the Province, and neighboring States. Fortunately in some sections refreshing rains have fallen during the last fortnight, and we should hope that there are but few localities that have not in some

degree been thereby benefited. In some districts the crops have suffered irretrievably, and cannot be expected to realize an average, while in others, owing to better soil and culture, and earlier showers, things wear a more promising appearance. The hay crop, generally, must inevitably be short, and the season has not been favourable to the sowing and germinating of turnips, carrots, mangels, &c.; extensive breadths of which have been put in; and however late this has been done, if the weather should from this time prove favorable, good returns may be expected. In this way the certain and great deficiency of hay may, to a great degree, be compensated. We have heard of some farmers sowing Indian Corn and Hungarian Grass with this view, and no doubt they will reap the benefits of it next winter in the better sustentation of their cattle. In a season of drought and cold like that we have been experiencing, the difference in the appearance of the crops on well and badly managed land is most striking. We observed the other day on a naturally good, and an extremely heavy soil, two adjoining fields in winter wheat. One had been thoroughly underdrained and duly cultivated; the other had not partaken of these ameliorating agencies, and the consequence is, that while the crop on the former looks far better than could be anticipated, considering the season, and promises, at present, to be highly remunerative, the latter must prove, however favorable the weather may yet be, *all out a total failure!*

### The International Exhibition.

LONDON, England, 28th May, 1862.

EDITORS OF THE CANADIAN AGRICULTURIST.—I have been every day since I wrote last at the Exhibition, except on Saturday last, when I went to the Sydenham Crystal Palace to see a Flower show and hear a Concert, both of which were highly pleasing, and were attended by some 12 or 13,000 visitors. One of the interesting sights to be seen was the playing of the numerous fountains, which was very fine, but continued only for a short time. They are supplied by water brought in by artificial means, and the expense, I am told, is not less than £50 for each half-hour. The one great defect in this really fairy-like scene is the want of a reservoir at a sufficient elevation to supply the water, but the whole is so grand and interesting that the defect

may be overlooked. Although the Palace is visited by such large numbers, it is said not to pay the stockholders. This is certainly a pity, for it is a most attractive place of resort, and it would be a great misfortune if it should be allowed to go down for want of funds. The expense of keeping it up, and making the improvements that are continually going on must be enormous.

But to return to the Exhibition—The jurors have been employed in the examination of the products of Austria and Hungary, where there is evidence to be seen of a convincing kind in proof of the productiveness of those countries. The wheats are many of them very fine, though as a whole, not equal to those from the Australian Colonies of Great Britain. The manufacture of flour is carried to the highest state of perfection. Indian corn, or maize, as it is called by the inhabitants, and in fact by every one here, is produced in great varieties, and of excellent quality. But the produce that seems to be the most abundant is beans, which are shown in endless varieties. What are called "chick beans" are a variety that, I am told, occupy as prominent a position in those countries, and are in as general use for human food, as oat-meal in Scotland. The manner in which the whole of the products are displayed is admirable, and reflects much credit on those who have had the control of them. No pains or expense seems to have been spared to make a neat and pleasing exhibition. Their wines are exhibited in great abundance and variety, and of vintages extending back for ninety years. I was yesterday invited to taste a wine 92 years old, and found it excellent. The wools of Austria and Hungary are of the very finest quality: and their manufactured woollen goods are, of course, of a corresponding description, and are exhibited in endless varieties and immense quantities, tens of thousands of pounds worth. The manufacturing processes of those countries are conducted with the greatest possible care and skill, and the products cannot be excelled. The prices marked on their goods, particularly the fine cloths, are such as I should think would tempt the merchants of many other countries, our own amongst the rest, to open a trade with them.

We are to-day to be employed in the examination of the products of Portugal. Their collection is very extensive.

I contemplate going to-morrow to the West of England Cattle Show. It is held at Wells, about 140 miles from here. From Wells I expect to go on to Exeter, about 80 miles further towards the Land's End. The Show at Wells is expected to be very good. It is said generally to come very near the Royal Agricultural Society's Shows in interest and extent. I shall be able to give you some account of it in my next, I hope.

Your's &c.,

E. W. THOMSON.

## The West of England Agricultural Show. —the International Exhibition.

LONDON, 4th June, 1862.

The weather, which has been during the most of May very wet, has set in with June very fine. Yesterday was delightful; and this morning is equally so. On Thursday, I went to Wells, a distance of some 120 miles, to see the West of England Cattle Show. The place is one of the most pleasant that could be selected. The grounds enclosed are on an inclined plane, sloping gently to the South, and from the highest part overlooking the finest panorama of scenery I ever saw. I went on Friday to Exeter, and returned thence to London.

On Thursday, while at the Show grounds, the day was very fine, but it came on to rain on that night, and Friday was a regular wet day, and must have produced the usual amount of discomfort at the Show. I was, however, on the cars, riding through an exceedingly interesting and beautiful part of England, as indeed is all the route from London to Exeter.

With the show, I was in some respects disappointed. The number of animals exhibited fell very far short of what I expected to see. There were a few very fine animals amongst the Short Horns, Devons, and Herefords. Horses were very poorly represented. Some good colts and fillies of the heavy cart horse breed, one or two Suffolk Punches, but I looked in vain for a thorough bred, or even a Cleveland Bay; there were a few ponies. The sheep and swine were good, the improved Berkshires being the prevailing breed of the latter, and very large and fine. In sheep there were some of the most beautiful Leicesters I ever saw, and which quite convinced me that very few, if any, of the sheep exhibited at our shows in Canada as Leicesters are pure bred. The Southdowns were perfect pictures. The Cotswolds are large, but fall far short of the others in point of symmetry. There were a few of the horned breeds, which, with their immense horns, and well developed carcasses, were majestic looking fellows.

The show of poultry was good. A cock and two hens were generally shown together in a crop or pen. They were certainly very fine to look at, though I should doubt their being worth the prices at which they were marked for sale, ranging from five to one hundred guineas. They were, I am bound to say, the finest specimens of the various breeds I have ever beheld, but the prices seemed to me to be ridiculously out of proportion to the possible value of the article.

In the Implement Department, there was a good variety of all the labor-saving implements and machines, and all of the best material and workmanship. I counted 24 Steam Engines in operation, all of the portable kind, driving threshing machines, straw cutters, turnip cutters,

fanning mills, and various other things. There is an important improvement in the threshing machines in the contrivance for shaking the straw. It does it effectually, and is much less cumbersome than the old plan. I hope that some of our mechanics will copy it. I will try and get an intelligible description of it.

I will now return to the Exhibition. We are not yet done with our inspection. We have got through the very extensive collections of France, Austria, and Hungary, all of which are exceedingly good. We have the products of one or two European countries yet to examine, and have to complete the examination of the products of Victoria, Australia, which have only just arrived, and are not yet ready for inspection. No country is able to produce such splendid samples of grain as Victoria, while the specimens of the products of her mines proclaim her wealth to be also immense in the useful and precious metals. The progress she has made within the last ten years is astonishingly great, and she is sparing no pains to make it manifest to the world by the very fine display of her products at the International Exhibition.

The Epsom races are going on this week, and seem to absorb the attention of the public very generally. As I write the road is full of people on their way there to witness or participate in the sports. I do not intend to go to the races, as they are not exactly in my line.

On Monday, it being the first one shilling day at the Exhibition, there were about 26,000 visitors. Yesterday the number increased to 35,000. There will no doubt be a gradual increase, as cheap excursion trains are advertised on all the railroads. Crowds of people will be able by that means to gratify their curiosity, and derive much instruction and benefit from seeing this the greatest display of the products of human industry the world has ever witnessed. It is now universally admitted that the Exhibition of 1862 far surpasses that of 1851 in interest.

There is one portion of the Exhibition to which it would be in vain for me to attempt to do justice. This is the Western Annexe, where the very extensive collection of manufacturing machinery is in motion, doing every kind of work, and producing a din and clatter that are deafening, but which at the same time is in a greater degree than I can express interesting and instructive. The English Artizans have not by any means got it all to themselves. France, Belgium, and the Zollverein have their extensive machinery at work, showing that they are not far behind their neighbors, and that they are willing to contribute to the utmost of their power in giving a further stimulus to the inventive genius of the age. Most glorious and beneficent must be the result of the united efforts of the world in this great International Exhibition of Industry and Art; and by no means an unimportant advantage is the bringing together of the inhabitants of the various countries of the earth

to form acquaintances which will give them better impressions of each other than they could acquire in any other way, or by much more expensive means.

Yours &c.,

E. W. THOMSON.

### Botanical Society of Canada.

A NEW FIBRE PLANT SUITED TO THE CLIMATE OF CANADA.

(From the Kingston Whig.)

His Excellency, Viscount Monck, has communicated to the Botanical Society of Canada some valuable information respecting a fibre plant sent forth from the Rocky Mountains by Dr. Hart to Lord Lyons, which the Society's Secretary has determined to be an *Asclepias*, and which is now under experiment in the Botanical Garden at Kingston. Since the publication of the various details in the Society's "Annals," the following communication has been received from His Excellency's Secretary:—

"The Governor General's Secretary is directed by his Excellency to transmit to the Secretary of the Botanical Society of Canada the inclosed copy of a letter from Dr. F. W. Hart, of St. Louis, respecting the mode of treatment pursued in the culture of the silk plant from the Rocky Mountains.

"Government House,  
Quebec, 2nd June, 1862." }

COPY.

ST. LOUIS, No. 64 Fourth St., Mo.,  
May 22nd, 1862.

To His Excellency Viscount Monck:

Simultaneously with a letter from Lord Lyons, one from the Secretary of Your Excellency (16th May) was received.

In answer to your request, relative to the treatment of seeds of the Silk Weed:—The Silk Weed is adapted to rich, moist, bottom soil. I recommend the London district, Canada West, or any where along the country the Welland canal runs through, or on the banks of the St. Lawrence, Canada West. The ground for planting should be prepared as follows:—Plow up four furrows, thrown together, then harrow down the ridge to pulverize it. Plant the seed about 12 inches apart in the centre drill made by the centre teeth of the harrow, cover lightly with the harrow or hoe; when the plant is three weeks old hoe the weeds away from it, then, with a light one-horse Yankee plough, bar off on both sides of the ridge, and about 6 inches from the plant, coming back immediately with the plow, and throw a furrow back to the plant, thereby hilling it in on both sides. If the season is dry, throw two furrows to the plant; the oftener the middles are plowed out, the more the plant will grow; it will not bear dirt taken away

from it, but will stand hilling; the larger the plant grows, the more dangerous to plow so close as to cut the plant; the side roots supply the branches and bulbs. After the 14th of August the plant must be cultivated no more; must be left untouched.

The Pods are ripe when they change color from a pea-green to a dark green and yellow. On pressing a pod it will split, when ripe; they ought to be gathered before they split open. Squeeze a pod open, and, with the thumb and forefinger of one hand, seize the silk where it joins the bottom of the pod, and the thumb and forefinger of the other hand, making a circular sweep; all the seeds are detached at one sweep, leaving the richest mass of satiney silk; the seeds to be thrown in one sack, the satin or silk in another. I have been precise in my directions, entertaining the most explicit confidence that the silk can entirely supersede the cotton plant. Its fibre or staple is longer and firmer, and of a gloss no silk or satin can match. During ten years I have planted cotton in Yazoo, Mississippi valley. My brand was sought by the Liverpool and Manchester speculator, and brought the highest prices; and on that practical experience I ground my convictions with regard to the Silk Weed, and, as a Canadian, I feel a double interest toward its success for Her Majesty's Government. I shall be happy on all occasions to convey to your Excellency any further information that may be required, and inclose you a few more seeds, and remain your Excellency's

Most obedient servant,

(Signed), FREDERIC W. HART, M. D.

\* Who knows but this fibre plant, Silk Weed or *Asclepias*, may, from its hardness, glossiness and fibrous texture, yet take the place of cotton, which could not grow in Canada, lying so far north as it does. But this plant, borne from the heights of the Rocky Mountains, may find a more congenial home in the less rigorous climate of Canada.

### Cotton.

*Editor of the Canadian Agriculturist.*

SIR,

The "Leader" of this day's date contains an interesting notice, transcribed from the "Kingston Whig," of a plant sent from the Rocky Mountains by Dr. Hart to Lord Lyons, and which, it is suggested, may be grown in Canada, and prove a substitute for the *Gossypium herbaceum* or "cotton-plant."

The plant in question has been pronounced by the Secretary of the Botanical Society of Canada to be an *Asclepias*; and is denominated "a new fibre plant."

A few additional observations respecting this plant may not be uninteresting to your readers.

The *Asclepias*, so called after *Æsculapius*—

the former name being Greek, the latter, Latin—belongs to the Milkweed family. The author of the article on Botany in the Edinburgh Encyclopedia divides this family into 51 species, Johnson and Paxton into 36, and Gray into 22. the plant referred to is by no means a new plant, if it is, as I apprehend it to be, the *Asclepias Syriaca*, for it was known as a native of North America in the year 1629. The "Lower Canadians" are, I believe, well acquainted with it, and are accustomed to use the Spring shoots as an esculent, and to stuff their beds with the cotton concealed within its pods. This cotton is, as described in Dr. Hart's communication, of the softest possible texture, and has, in consequence, been called "Virginia Silk." In the Edinburgh Encyclopedia but two habitats of the plant are named, — *Virginia* and *Astracan*. Of the 36 species described by Paxton, 24 are natives of North America, and 26 are hardy.

There is one of these Milkweeds, *Asclepias tuberosa*, the Pleurisy-root, with whose beautiful bright-orange umbellate blossoms the inhabitants of Peterboro' are doubtless familiar; and others of the same family may be found in our neighborhood.

I imagine that there would be no difficulty in cultivating the Silkweed in Canada, by sowing the seeds in a very light soil and giving them plenty of room; but whether its cultivation would eventuate in the beneficial result anticipated by Dr. Hart is another question, and one more difficult of solution. The experiment may be at all events worth a trial. Sugar, if I mistake not, has been manufactured from its blossoms.

I am, Sir,

Your obedient servant.

V. CLEMENTI.

Peterboro', June 23, 1862.

[If the plant referred to in the foregoing communications is the common milk weed, so well known as a troublesome weed in many parts of Canada, as we are inclined to suppose it to be, from Dr. Hart's description, any expectations of its proving valuable for manufacturing purposes will, in our opinion, certainly be found fallacious. The silk, though beautiful to look at, has no more strength or tenacity of fibre than thistle down, and we doubt its being of much more value for any useful purpose.—Eds.]

(ne plant of the wild carrot (*Daucus carota*), having 600 flowers and two seeds to each flower, gives 1,200 seeds.

One plant of the wild parsnip (*Pastinaca sativa*) gives the same as the above.

There are several varieties of barley shown, two-rowed, four-rowed, and naked barley. There are several beautiful bright samples, the weights of which are stated to be, two-rowed 58 lbs and four rowed 46 lbs per bushel. From the evidence before us, we should expect that Canada is capable of producing superior qualities of barley, adapted for the production of high hopped ales, such as are brewed at Burton-on Trent, by Bass and others. The oats, beans and peas are of various kinds, the whole of the samples being distinguished by a general excellence. Lower Canada shows some very good specimens of the maize or Indian corn, showing how much even a short summer, if dry and hot, can do to ripen this plant, which hates moist skies and loves the

sun. The samples of maize shown are of the white and yellow varieties. The cobs of maize are large, and the samples of the grain are generally excellent. Buckwheat, linseed, and samples of flax straw are also shown. The flax and flax seed give promise that Canada may yet become an extensive exporter of seed and fibres.

Another proof of progress in agriculture in Lower Canada is furnished in the exhibition of drain tiles, manufactured there by the Missisquoi Drain Tile Company and others. A very short time ago there was not a thousand acres in Canada properly drained with tiles. Now it is becoming a matter of contest who shall use the most and soonest. Back from the plain districts we have named, stretch hilly, broken pasture lands, abounding in wild romantic scenery, plentifully watered with mountain streams, and affording an excellent grazing country during the summer months. There, oats; root crops, and grass are the staple products, but they are very indifferently represented here. There are some specimens of timothy and clover seeds; these are good, and clover seed might form a far more extensive part of the exports of Canada than at present. And to represent the produce of the dairies, we have a single cheese of a decidedly American style of manufacture, and one little crock of excellent butter, which comes, however, from an esteemed correspondent, Mr. James Logan of Montreal. In Canada the farmers make a great portion of the sugar they use from the sap of the maple tree, and there are exhibited several good specimens of this—those from Lower Canada being decidedly the better. A bale of hops is also shown, grown on the island of Montreal, of very excellent quality, but not very carefully picked.

We turn next to the Upper or Western Province—the great wheat producing district, and concerning its products we have the advantage of information gathered from Colonel Thomson, a leading agriculturist there, and President of the Board of Agriculture. He is also a juror in this class at the exhibition. Specimens of winter wheat are exhibited from the counties of Durham, Peel, Wellington, Lincoln, Wentworth, Oxford, Brant, Elgin, Kent, and Lambton, extending over a distance of 250 to 300 miles from east to west. Here are comparatively new soils, admirably adapted to the growth of wheat, as yet in very few instances exhausted. The farmers of Upper Canada, warned in time, are beginning by careful cultivation and rotations to guard against the evils suffered in the east, and in parts of the United States, though it is still too common a practice to grow wheat, as the most saleable product, year after year.

There are twelve good samples of half a bushel each. One quality of the wheat is good, being generally plump and of a bright clear colour; a portion are white wheats, average weight about 62 lbs. per bushel. One sample shown by Mr. Fleming, seedsman, Toronto,

weighs 66 lbs. The samples exhibited are all white wheats of highest commercial value, and are grown in all parts of Canada West. The usual quantity of seed sown per acre is  $1\frac{1}{2}$  bushels, and the yield is, when the soil is properly cultivated, from 16 to 40 bushels per acre, according to season and other circumstances. The average amongst good farmers is about 25 bushels; but a too numerous class of cultivators do not get an average of more than 13 bushels. The most reliable information Colonel Thomson has been able to collect (covering a period of ten years), gives a general average of 17 bushel per acre. 45 and even 50 bushels have been obtained in some cases in particularly favourable seasons. Their best wheat lands are marly clays and gravelly loams, with more of the calcareous element present in the soil.

The winter wheats are generally designated as "Soule's," "Blue Stem," "Red Chaff," and "White." These, I am told, are the best varieties of wheat grown in Canada, and command the highest prices in the Canadian markets, and those of the adjoining state of New York, being much sought after by the millers of that State to mix with inferior wheats grown there and in the Western Federal States, the flour being thereby made to command a better price for home consumption or export.

As to the name of Soule's Wheat, it is said to have been first introduced into Upper Canada by a person of that name, being brought from the State of Virginia. The Blue Stem has very naturally taken its name from the fact that the stem or stalk is of a bluish colour. One of the recommendations of this variety is that the straw is stiff, and never lodges, and consequently is easily harvested.

The old Red Chaff White has long been favorably known in Canada, as has also the Velvet Chaff; but the latter is now rarely met with. Another variety that was in favor ten or twelve years since, was a bearded wheat known as the "Michigan," having been introduced into Canada from the State of that name. It was supposed to resist the ravages of the fly better than any other; but the grain was found not to yield as much flour as the other varieties; consequently it will not now command so high a price.

The spring wheats shown are common to Canada East and West—some of the finest being grown in the vicinity of Montreal.

The Fife is an early wheat, and comes to maturity even when sown a month later than the date at which other spring wheats are sown. The ear does not appear until it is too late for the fly to deposit its ova in it. Being besides a good wheat, both as regards productiveness and its value to the miller, it has become a general favourite. It is a red wheat, and without awns. The Golden Drop is a fine wheat, it being also as well as the Black Sea wheat, without awns. There are besides one or two samples of bearded wheat shown, but they are not favourites.

The yield of spring wheat is often as high as 35 bushels to the acre; 20 to 25 is common on ordinary lands, and it does well to follow a root crop or maize (which are similarly weeded with hoes), and to be sown out with grass seeds. A mixture of Timothy and Red Clover—four lbs. of Timothy and six lbs. of clover per acre is the usual quantity sown. These wheats are not worth so much by ten per cent as the autumn sown wheats, as they do not yield flower that will bear transportation so well. In some parts of Upper Canada, however, where winter wheat was formerly grown, the spring wheat has superseded it. This change has occurred principally in this wise—During the severe frosts of mid-winter the growing crops and grass are protected from harm by the deep coating of snow under the deep coating of snow under which they are buried. While the fields are defended from the bleak winds by the kindly shelter of the surrounding forests, this protective covering was pretty well assured. But as the country is denuded of the trees the winds sweep over all the plains and exposed places, and the young wheat and sometimes the grasses themselves in the meadows are so frozen as to be what is termed “winter killed;” of course spring wheat is not exposed to this danger. Of the excellent fruits grown in Canada, none are shown here, but some very good coloured lithographs of the natural size. The Royal Agricultural Society, London, have invited all the world to a contest for superiority, at their October show, and we are given to understand that Canada is likely to be a not unsuccessful competitor. Melons, cucumbers, and tomatoes are grown in almost all parts of the colony, in the open air, and the standard peach gives excellent fruit at Montreal, and throughout the southwestern province.

Several fruits are produced in great perfection in Canada, the soil and climate being generally well adapted to for the growth of the apple, pear, &c. With the view of showing the capabilities of the colony, there are exhibited 114 coloured plates of the fruits. These plates are beautifully executed, and are stated to represent the natural sizes of the respective varieties of the fruits produced in the open air. The plates were prepared by the Fruit Grower's Association of Upper Canada.

*Written for the Canadian Agriculturist.*

### Hints for an Agricultural Report of the Township of Hamilton.

The Township of Hamilton is the most westerly township in the County of Northumberland, and may be said to lie between Lake Ontario on the South, and Rice Lake on the North.

The land for two or three miles from Lake Ontario is generally level; the soil is clay or a strong clay loam; behind this level ground there is a series of small low hills, and undu-

lating land, which seems at some former period to have been the lake beach. The soil on this rolling land is generally lighter, in some places gravelly, in others covered to an inconvenient extent with boulder stones; such as geologists attribute to the action of icebergs. Behind this we reach the highest land between the lakes, commonly called the “Plains.” These heights and plains reach nearly to Rice Lake; they are, generally speaking, covered by from two to six inches of light yellow sandy loam, almost destitute of vegetable matter, except where the action of some streamlet has caused a difference in the character of vegetation. But their peculiarity lies in their subsoil; up to a recent period this was thought to be very inferior, but it is now ascertained to consist in many places of heavy brown, or reddish clay, in others of whitish clay, mingled with friable limestone, and in a small minority of cases, as far as our information goes, of sand. These plains were formerly thought unworthy of cultivation, but have now been found to produce good crops of wheat (both of fall and spring); and in fact to grow profitable crops of all kinds of farm products. The township is stated by last census to contain 40,891 acres under cultivation, and the cash value of the farms is set down at \$2,254,929. To this ought to be added the land under *farm cultivation* returned for the town of Cobourg, which is situated in this township, viz., 1009 acres valued at \$177-350. Annexed to this report will be given a tabular view of the different agricultural productions, and the quantity of land under the different crops, as far as these can be ascertained from the returns of the late census.

In preparing a few hints for an agricultural report, we intend noticing briefly: Horses; the different breeds of Cattle that are reared in the township, Sheep, Pigs, the various Agricultural Productions—the Insects or Diseases that have affected our crops—Improved Implements—Agricultural Societies, &c., &c. At the outset, we would say, that few townships have been more fortunate in having been settled by an enterprising class of farmers, who have successfully introduced the various breeds of cattle, &c., as the number of premiums awarded to farmers in this township at the various Provincial Exhibitions abundantly testify, a list of which prizes, as far as we can ascertain them, is annexed.

**Horses.**—The township has perhaps paid less attention to the improvement of the breed of horses than to any other of our farm stock. This may partly be accounted for by the nearness of all parts of the township to market, so that the horses were more employed on the farm than used on the road; still there are many good teams in the township, and a

marked improvement has taken place in late years. About 1840, the County Agricultural Society, among other improved stock, introduced the stallion "Ploughboy," who was mostly kept in this township; and though his stock grew rather slow at first when young, yet they proved very useful, hardy horses, both for the farm and the roads. Indeed, some of the best horses in the township are from his stock. Some years after this, the late Mr. John Mason, of Cobourg, brought in "Clyde Britton" a stallion of the celebrated Clydesdale breed, and for a few years he was a great favorite with our farmers; but his stock hardly answered the expectations formed of them, though they made rather useful farm horses. The Township Society for two successive seasons offered a handsome premium for a stallion to travel in the township. The first year the premium was awarded to a horse of the "King Alfred" breed; the second year to one of the "Rainbow" breed. The stock of both promise to be useful, and an improvement on our former breed of horses. N. Grimshaw, Esq., has imported from England one of the celebrated "Suffolk Punch" breed of horses; and has travelled him for the last two or three years; his stock has not been sufficiently proved yet to enable us to judge fully of their merits, but we trust they will be a great improvement to our breeds of horses, and prove amply remunerative to his spirited importer. The Messrs. Underwood have this season brought in from the west, a fine large horse, the "Royal Prince of Wales," and are now travelling him through the township.

*Cattle.*—Following the order of their introduction, as well as that of our prize list, we shall notice, first, the "Durham," or as they are more appropriately called, "the Improved Short-horns." Of this class, the first one was brought into the township, as far as we know, by the late Mr. Robert Wade, of Maple Grove, who introduced the bull Forester, some thirty years ago; his stock was a great improvement on the breed then common among our farmers, and laid the foundation for much of our present improved stock. Mr. Wade followed up the stock of this bull by others; and at a later period, imported some fine heifers of this breed from England. When he retired from farming, his stock was sold by auction at high prices; and was widely scattered over this and the neighbouring townships. In this field, he was followed by his sons, John Wade, Esq., of Hamilton Gardens, whose stock is well known, and is now the largest and finest of this breed in the township, and also the late Mr. Ralph Wade (who was killed at the unfortunate Desjardines Bridge accident), made several importations from England, in which he met with great losses by deaths of stock at sea and otherwise. His stock was mostly

sold after his death, and were thus spread over the country. His family still retains part of the stock.

George Roddick, Esq., has imported several superior animals of this breed from Britain. His stock is well known, and is fast spreading over the country. There are several other owners of this class of stock in the township; but we are not aware of any other breeder that has imported from abroad. A. Alcorn, Esq., has a small herd from imported stock. All the above named breeders have been awarded prizes for their stock at our Provincial Exhibitions.

*Devons.*—This breed has never been held in such favor by our farmers, as the Durhams, nor are their grades so widely spread in the township. The first bull of this breed, so far as we know, was introduced by Thos. Eyre, Esq., and afterwards became the property of the late John Mason; when in his possession, this bull, "Billy" gained many both local and Provincial prizes. At our earlier Provincial Shows, Asa A. Burnham, Esq., and Mr. J. Mason were among the most successful exhibitors of this class of stock. The principal breeders in the township at present are the Messrs. Eagleson, and Wm. Mason. We are not aware of any of them having imported any stock, and they have contented themselves with local honors, as none of this breed has been shown from this township at any of our late Provincial Shows.

*Ayrshires.*—This breed was much later in being brought into the township than either the Durhams or Devons. Mr. Robert Brown when in this township, was the first to bring in an Ayrshire Bull, and his stock proving excellent, especially for dairy purposes, he was encouraged to buy an imported bull at one of our Provincial Shows, which still further improved his stock, but the principal, best known, and most successful breeder of Ayrshires is P. R. Wright Esq., whose stock besides all the other prizes, both local and Provincial which they have taken, took the premium for the best herd at the two last Provincial Exhibitions. Mr. Wright in beginning his herd, had the misfortune to lose his first importations; which were all lost at sea on their voyage from Scotland.

*Galloways.*—This breed of cattle is the latest of the improved breeds that has been brought into the township; they were introduced here by Mr. Wm. Roddick, who imported from Scotland some fine specimens of this breed in 1854, (amongst the first ever brought into the Province.) They have proved very hardy, and suitable to our climate, and are fast spread over the country; although there are many grade animals of this class in the township, there are no full bred ones except the stock of

George and William Roddick, whose herds have figured in our local and Provincial Prize List for several years past.

These are the principal full bred herds in the township. The great mass of the cattle are still, and will probably long continue grades—of the various breeds, chiefly Darhams, which are most widely spread among our farmers here—as they are all over the province.

**Sheep.**—In no class is there so much improvement shown as in sheep, and they are more generally diffused among our farmers than any other kind of stock; it has become very uncommon to see any of the old common breeds, even among those sheep that are still turned out to pasture on the roadsides and woods during summer. Among the first introducers of improved sheep was the late Mr. Robt. Wade, who brought some of the "Teeswaters" into the township; shortly after Mr. Wm. Brown imported some "Leicesters," and from those the first great improvement of our sheep stock was made. The late Mr. Ralph Wade made several large importations of "Teeswaters or Improved Leicesters." Mr. George Roddick, Mr. A. Alcorn, Mr. R. Hume, Tyndale, Mr. Wright and others have made importations of this variety of sheep, and many others of our farmers have either imported or procured from imported stocks, and are in possession of fine flocks which are both profitable to the owners and creditable to the township. Mr. Wm. Roddick imported some of the "Cheviot" breed of sheep in 1854, the first, we believe, brought into the Province. They have not been received with the same favour as the "Leicesters," and the full bred ones are still in few hands; their hardiness, comparatively fine wool, and a disposition to fatten readily at an early age, render them a very suitable breed for the country. The fine woolled breeds have never had much attention paid them in this township; which is rather surprising, considering that we have the well known "Ontario Mills" woolen factory in our midst, which uses a very large quantity of fine wool, that has to be imported; thus sending money out of the country that might be beneficially kept at home. We think if some of our spirited and enterprising farmers would try a flock of fine woolled sheep it might prove profitable to themselves, besides being a benefit to the township. A. A. Burnham, Esq. has a small flock of Southdowns, the only one we know of in the township—they took several prizes at our earlier Provincial Exhibitions. Mr. Thos. Taylor imported a few of a breed called South Hams, but they were not received with much favour, and we don't know of any of the breed kept pure.

**Pigs.**—In looking over the Provincial prize lists we observe that our Township has taken fewer prizes for Horses and Pigs than for any other class of stock; still though we have very few noted pig breeders, our pigs are generally improved—it is seldom we now see those speci-

mens of the *genus sus* known by the names of *Land pikes* or *Razor backs*, which used to be common. The pigs in the township are generally white in colour, and fatten easily at an early age, but as we are near a market for all kinds of coarse grains they are not kept in large numbers, nor thought very profitable by our farmers generally.

P. R. Wright, Esq. introduced the Suffolk breed, and was a successful competitor at several of our Provincial shows, but though crosses of this breed are to be found, the pure breed never spread much in the township.

(To be Continued.)

### The Value of Coal Ashes and Cinders.

Coal ashes, is as a general thing, thrown away and thought a nuisance. But after some experiments, I am inclined to take a different view of the matter.

It may be, and undoubtedly is the case, that they are less valuable than those derived from wood. The ashes of coal contains gypsum, lime, and phosphoric acid, but its main bulk is composed of insoluble silica. I have found coal ashes to be very useful in the peach orchard; in the fall they should be spread around the root of the tree at the rate of of a good sized wheel barrow load to each tree, and spread some five inches thick at the trunk, and sloping off gradually all around; the ashes should be allowed to remain in this position until the tree is out in blossom, when it should be spread over the orchard. I consider that I have derived much benefit from this plan, and would account for it in the following manner. We all know by experience that a large pile of coal ashes will retain the frost much later than common soil—the ashes at the trunk of the tree (as I have proven by experiments,) retains the frost later in the spring, and prevents the tree from coming out in bloom too soon. Another good effect is that ashes thus applied will keep off the peach-worm, which is often so destructive to the trees. Besides these mechanical advantages, coal ashes contains snbaucues which are beneficial to vegetation of all kinds. Last winter I kept a portion of coal ashes under shelter until the ground was well frozen, when it was spread as before; if the effect should be thereby changed, I will report at the proper season. This system will apply as well to the other fruits as to the peach. I have tried it with the same effect on apple, pear, and cherry trees.

If coal ashes produced no other effect than the mechanical one of loosening the soil, it would still be valuable. But the following analysis by Professor Norton, proves it to be valuable as a manure. He found one hundred parts of ash

from white ash coal without any wood ashes from kindling, contained of

|                  |       |
|------------------|-------|
| Insoluble silica | 88.08 |
| Soluble,         | 0.09  |
| Alumina,         | 3.36  |
| Iron,            | 4.03  |
| Lime             | 2.11  |
| Magnesia,        | 0.19  |
| Soda,            | 0.22  |
| Potash,          | 0.17  |
| Phosphoric acid, | 0.20  |
| Sulphuric acid,  | 0.86  |
| Chlorine,        | 0.09  |

Those who advocate the application of Iron to peach trees will find another reason for my success in the amount of that substance contained in coal ashes

One of my neighbors has for many years applied coal ashes to his potato patch as a preventive of rot, and has not since been troubled with rotten potatoes. He retains the same piece of ground several years in succession, and applies coal ashes in large quantities each year. He attributes his success to the loosening or mechanical effects of ashes, but I attribute his and my own success in this line to early planting and early digging.

As to whether it will pay to buy or haul coal ashes far, I cannot say, but by the above analysis we see that nearly ninety pounds in every hundred is of no value as a manure; that the whole potash from one ton of coal ashes would amount to but three pounds, which may be obtained at a cost of twenty-five cents; the sulphuric acid would amount to but eighteen pounds in the ton, and would cost but about sixty-two cents. Apart from the insoluble matter the ashes would be as valuable as some of our patent fertilizers. —*AGRICOLA in Germantown Telegraph.*

## Necessity of Land Drainage in the County of Essex, C. W.

(From the *Essex Journal*.)

No County in this Province needs drainage more than the County of Essex, and when properly drained, no county could surpass us in our Agricultural productions. Our soil is most fertile, our climate very healthy, and the great drawback to our advancement and prosperity is the want of drainage. Thousands of acres of beautiful land are to-day immersed, which might be made productive of much good, and offer to emigrants, inducements unequalled in any other part of Canada. There is no trouble to find a market for all that can be produced, a railroad, and the Lakes and River Detroit, affording every facility for shipment.

In view of this subject, Mr. Weaver, Vice-President of our County Agricultural Society at its last meeting, said:

"In travelling through parts of this county,

I find a great deal of waste land and crops, for the want of proper drainage. The farmer both loses his time and seed in working his land, and loses his crops also.

I would move that every farmer make up a statement giving the amount of his crops lost through wet, or water lying on the land so long that it prevents him from working it; also stating whether it is practicable to drain the said land, and, if so, where to and what distance, whether to a known creek or gully, and through whose land, whether wild or occupied, and of what advantage it would be to the neighboring lands, if within his knowledge. Also, farmers who have ditched and drained their land, stating the advantage they have received by such drainage.

These communications to be sent to James Woodbridge, Secretary of the County Agricultural Society, so that they may be forwarded by the President to the County Council, for them to deal with as they may think best and proper, for I am really of opinion that there is from eight to nine per cent. of labor, seed and crops that are entirely lost to the farmer.

I hope these remarks will meet with the view of the Directors, for I really think that it is one of the first things that should come under the notice of this society. For Agricultural purposes, our county is second to none in the Province. We have the advantage of a water communication all round us, and a railroad in our centre, so that our farmers have no distance from their own door to seek a market for their produce, if the surface water is taken off, or that the roads may be passable."

## The Army Worm.

It may be recollected that among the wonderful characteristics which some writers, last year, asserted were possessed by the army worm was that of propagation while in the larva state. This of course was denied by all who understood the natural history of insects. The subject has been revived by a correspondent of the *Valley Farmer*, Mr. S. Washington. He states that in various examinations last year, he found small, white worms about an eighth of an inch in length, in the bodies of army worms—the numbers in each army worm varying from fifteen to fifty-four.

The editor of the *V. Farmer* submitted the statement to Mr. B. D. Walsh, of Illinois, a well-known entomologist, to whose writings in regard to the army worm we have frequently had occasion to refer. The point to which Mr. Walsh's attention was called, was, whether the worms found in the bodies of the army worms were of the species, and if not what they were. On this Mr. Walsh says:

"They were, beyond doubt, the larvæ or grubs of some species of ichneumon fly, whose habit it is to stick its eggs into the body of the

living army worm, with a long piercer which it has at the hind end of its body, and which a wise Providence has given it for the express purpose. These eggs hatch out, and the grubs proceed ing from them—which have no feet, because the Being that made them knows that in such a situation they have no need of feet—feed on the flesh of the army worm, avoiding the vital parts, but finally destroying it. They then eat their way out, spin a little cocoon of white silk like a grain of rye, only made smaller, inside which they change into the pupa state; and after a few weeks they make their third and final change into the imago or winged state, burst through the silken cocoon, and come out into the world in the form of four-winged flies, known to entomologists as ichneumon flies. Of the three kinds of ichneumon flies which I have myself bred from the army worm, one kind comes out as a general thing without wings—and in that state looks much like an ant or pismire. It may easily, however, be distinguished from an ant by its horns (or antennæ) not being flail shaped, or elbowed, as those of all ants are."

Mr. Walsh states that the popular idea of army worms being killed by the sun, is not well founded; that the dead worms which are found in situations supposed to justify this belief, are not killed by the sun, but by the ichneumon flies. He adds that the farmer, instead of being alarmed under the idea that the army worms propagate in the larva state, "ought to bless Heaven for sending into the world these tiny little flies, whose special mission it is to prevent the army worm from increasing beyond its appointed bounds. There can be no question that if it were not for the check which ichneumon flies and other parasitic insects form on the unlimited increase of plant-feeding insects, the world would soon become a desert."—*Boston Cultivator*.

### The Edinburgh Sewage Meadows.

A committee of the the House of Commons has been sitting some weeks on the subject of town sewage—on the possibility of turning it to agricultural account, and so of converting what is now a poison into a food. Much of the evidence taken has been based on an experience so limited as to render it untrustworthy as the foundation of any recommendation which the committee may be expected to make, and a good deal has been vague, not to say unsatisfactory. There has, nevertheless, for many years been ample experience of the agricultural value of town sewage on a large scale, and there has long been a sufficient body of concurrent evidence on the subject.

No committee was needed to make it known either that sewage is at present generally both mischievous and wasted, or that in some localities it has been profitably put to use; while in

others it has been made expensively harmless. Edinburgh, Glasgow, Ayr, Carlisle, Mansfield, Rugby, Leicester, Birmingham, Watford, Croydon—some for longer time than others—have most of them been known as the scene of great sewage operations and experiments. The collection of evidence from men whose experience of "town sewage" is derived from the waste of one household, and whose farm sewage includes the liquid manure of half-a-dozen beasts, can only impart uncertainty and doubt—if it all tends to belie the great facts with which most of us are already well acquainted.

What are the main grounds on which it is believed that town sewage can be turned to good account? Having lately visited Edinburgh, Glasgow, Ayr, Carlisle, Rugby, and Croydon, and walked over the ground thus manured, we are able to give the testimony on this question of an eyewitness as to those localities.

1. The streams which wash out Edinburgh are used for the irrigation of grass lands at Craighentinn, Lochend, Grange, besides certain meadows west of the town.

a. The meadows at Craighentinn lie to the N. E. of Edinburgh, at the foot of the valley which drains two thirds of the ground on which the town stands. They are 190 acres in extent, of which 40 acres or thereabouts lie close along the shore, a narrow strip between it and the coast railway. The land is for the most part a free soil—next the sea it is a light sand—in places inland it is stiffer. It is a fan-shaped plot; the water enters at the handle, and travelling along the outsides, is diverted to one or other of the "pares" between the outward artificial channels and the old water-course. It is let in pieces varying from a rod to an acre in extent, and has this spring fetched prices varying from £20 up to £41 10s. per imperial acre.

The sandy pieces next the sea let from £20 to £25 per acre, the inferior produce here being due partly perhaps to an original inferiority of soil, but chiefly, we imagine, that the water which pours over it has been used, all of it once, some of it twice before. At least half of the meadow is thus irrigated with tail water, and indeed it may be said that all of it is to some extent thus watered; for the Lochend meadows lie higher up the stream, and a quarter of the "Foul Burn" is diverted for use there, rejoining the main stream after having left much of its fertilizing contents behind.

The lighter portions of the land yield the earliest swathe and come quickest to the scythe again. We saw a swathe cutting on the 23rd of April, which must have weighed at least 10 tons per acre. There is, we believe, nothing elsewhere like it known to English agriculture. This great quantity is the result not of a very tall, but of a very thick growth. The blades of grass are not more than twelve to fourteen inches long, but they stand so thick and the

stem of each is so soft and succulent and large that the lower part of each is blanched, and the stubble left is white.

In a day or two, or immediately after the whole grass of any plot is taken away, the water is let on. The whole as to arrangement is a rough specimen of the ordinary ridge and furrow plan of irrigation, and the supply seemed to be ample according to the practice of the ordinary water meadow—forming a thin skin of flowing water, visible everywhere on the surface of the land. A stream 2 feet wide and 1 foot deep, running at the rate of a mile an hour, was in one place supplying what we judged to be an acre of the land. This corresponds to 10,000 cubic feet per hour, and as the supply is kept on foot for about five hours at a time, it is equal to from 12 to 14 hundred tons per acre for a dressing. Such a dressing is generally all that the plot receives until the next cutting; but as during the season of growth all the stream is kept in use, excepting at flood times,\* and all is watered in rotation, it may happen that another dose is available for the same land during the four to six weeks' interval which elapses before the swathe is again ready for the scythe. If there should be an opportunity of giving it a second dressing within three weeks or at least a fortnight, of that time, the opportunity is taken.

From three to five cuttings are taken during the year—the first is not the heaviest, and indeed the cow-feeders who hire the plots are tempted to take the earliest earlier than they should both for the sake of an early bite of grass and in order that a fifth swathe may be taken in October. Putting four cuttings as the average, and remembering the water is laid on to some extent during the winter season, it is not too much to estimate that every acre of the Craigentenny meadow receives 10,000 tons of sewage during the year. For this an average produce of at least £25 or 6-10ths of a penny a per ton may be obtained; and as this (half the meadow being watered with tail water) is obtained a second time, the whole worth extracted from the Edinburgh sewage here is rather more than 5 farthings per ton. As an additional illustration of the experience here, it may be supposed that the waste of 80,000 persons, probably imperfectly gathered however, is here utilised, and as the Lochend and Craigentenny lands amount to about 230 acres, that is at the rate of more than 300 persons per acre!

As to the cost of operation—taken in one view it is hardly anything; the sewage is obtained for nothing, the work of management does not cost more than 20s. a week at Lochend, and at Craigentenny it is managed by two men, and

probably costs under £100 a year. But if any company or new proprietary proposed to undertake the work, they could not purchase the apparatus (the estate) under £500, perhaps £600 per acre, which is two shillings or more for every ton of the swill which is turned to account upon the land.

b. The Lochend meadows lie above Craigentenny. About a quarter of the Foul Burn is diverted and sent along the narrow grassy valley over which it is here spread. The plot is about 30 acres in extent, of which one third may lie on the north-western side, about one hundred yards wide, sloping 1 in 25 or 30 towards the old water-course below; a quarter on the south-eastern side, a narrower strip, rather steeper; and the remainder is on the flat below. By reason of certain alterations upon the level of a main stream, the out-fall to the drainage of the last portion has been temporarily stopped, the effect of which is very visible upon the crop. The plots—half an acre to an acre each—into which the whole is divided have this year let for £18 10s and upwards on the flat, and for £25 up to £39 10s. on the sides. Drainage is an essential part of successful irrigation. Soil, as we are told by the intelligent superintendent here, is like man or any other animal; no nourishment of it is possible unless the food pass through it. You may present as much nutriment as you please to the surface, or the mouth, but in either case a stoppage is fatal. This is well seen at Lochend; patches of imperfect drainage, even on the steep sides of the valley, at once show the same defective growth, which is much more generally visible on the undrained flat at its foot.

Men and carts were busy removing a heavy swathe of grass on the 23rd of April. The grass is in many places, both here, and at Craigentenny, very weedy—full of crowfoot; but the cows eat it all with greediness; and it is, indeed, very probable that the bitter of the ranunculus may be a wholesome corrective of the extra succulence of the growth. Be that as it may, the whole is removed and carted, much of it to mles to the cowhouse. The price of the food thus purchased growing on the ground must be at least 10s. a ton. When sold by weight it varies from 6d. to even 1s. a cwt., according to the demand. And the price per acre forbids our imagining it to cost less than the lower of these prices on an average throughout the year. Mr. Taylor, the farm manager for Mr. Scott, who is the tenant of the Lochend estate, considers it of importance not to let the water on until the scythe wound has fairly healed; and some natural, unassisted growth of the stubble has taken place. It is thus a week or ten days after a cutting before it is irrigated. The water is, however, then let over from 24 to 48 hours at a time; and as it is apparently at the same rate per hour as at Craigentenny, 4 or

\* One man manages the distribution of the water, but he has an assistant, so that between them a watch night and day is kept especially for the diversion of a sudden flood, which is at once turned to waste; others are employed at busy times, and especially in cleaning out the water-carriers.

5 times as much water is thus put on; and taking the produce at the rate already stated, we do not suppose that a farthing per ton is here made of the sewage which passes over the land. This, however, for about a quarter of the stream, as already said, has to be added on to the sum already named as made at Craightenny.

Besides the 30 acres of natural meadow where the sewage is thus used, Mr. Scott has 10 acres of higher land close by, which he manages to irrigate jet-fashion by subterranean pipes and surface hose. The stream diverted from the north-western side runs, about 500 tons per hour, as we estimated it, along a channel by the upper edge of that side of the valley, and perhaps 10 or 12 f et above the channel below. A portion of it is taken over a water wheel, and this by a very simple arrangement of leverage and gearing, works four pumps, each delivering about one fifth of a cubic foot at a stroke, and making about 25 strokes per minute. These 20 cubic feet of water per minute, equal to 30 tons per hour, are delivered by Iron piping and hose at the rate of half an acre daily, or perhaps 600 to 800 tons per acre, over Italian ray-grass after each cutting. The land is an extremely light sand, with a deep sand-pit in the middle of it, and it is said that 30 tons per hour delivered in the ordinary way the ground in surface channels would sink so rapidly, that the whole surface could not thus be wetted evenly, and the apparatus of hose and jet is thus made necessary. This piece of Italian ray-grass is let in half acre plots like the meadow, and fetches £25 an acre. It is sown by hand at twice, about 3 or 3½ bushels per acre in early autumn, not watered until after the first cut in the following May, and then watered only gently and with caution, until the plant is fairly established. It is kept a second season, receiving then, as well as during the summer and autumn of the first year, a full allowance, and it is ploughed down in the autumn of the second year. A crop of early potatoes is taken in the third year, and the land is then again prepared for the seed.

c. The Grange meadows, the property of Sir J. Dick Linder, extend over about 20 acres, near Newington, a southern suburb of Edinburgh. The north side is watered from two streams, one of which is fouler than the other, and the grass is proportionably richer there. We saw on several plots a growth equal to any of Craightenny or Lochend, which had fetched close on £40 an acre. On the south side of the valley the surface is watered with clear water—not fouler than in any ordinary village stream—and the difference in the produce of the two sides is very remarkable. The rents obtained on that side vary from £12 to £15 per acre; on this from £25 to £40. The soil, as shown by market gardens close by, is a loose loam.

d. Let us now follow this grass home. Mr. Sanderson, a cow-keeper in Murray street, off

the East Cross Causeway, keeps 30 cows, chiefly short-horns. He has taken seven plots of meadow land for them on all the different meadows we have named, paying £100 for them. Two plots have been taken at £26 10s per acre each; one at £31, one at £38, and one at £27. two (being Italian ray-grass at Lochend) at £27 10s. We may suppose that he has thus secured 200 tons of green food, equal to rations for his cows during 160 to 180 days of summer. He finds it capital milk-producing food. Notwithstanding these enormous rents—notwithstanding a distance varying from ¼ to 3 miles of carriage—notwithstanding that he is extremely liable to loose the milk of his cows by the foot and mouth disease, and his cows themselves by pluro-pneumonia, yet we could learn that his business prospers. A cow may last a year, and be sold fat, or she may last two months and die—there is much loss and injury, owing to the place of these being filled by purchases in the market, where infection of either pluro-pneumonia or distemper monia is indigenous; but notwithstanding all these costs and risks, a living and a profit are made by cow-keeping. The management is as follows:—The cows receive about 1½ bushels apiece daily of “draff” from the distilleries—spent malt or “grains”, as we call it—they get this all year round, and from ¾ cwt. to 1 cwt. of grass daily during summer, and about 1 cwt. of turnips, partly steamed, during winter, with straw or fodder all the year round. In illustration of the cost of feeding, the price of the grass has been already named, the “draff” costs 3s. a quarter, the turnips from 15s. upward per ton at the railway station, the straw 3d. to 4d. a stone. The sales are, milk at 9d. to 10d. a gallon; cream at 8s. a gallon, and about £140 worth of dung annually (nearly £3 per cow), which is bought and carried away by neighbouring farmers.

These particulars, then, may suffice as an account of the Edinburgh sewage meadows. We did not see those on the west side of the town, except from the railway carriage—they appeared as full of grass and as busy with men and as busy with carts removing it (April 23rd) as the others. What has been already stated sufficiently represents the Edinburgh experience on the subject of town sewage. We have yet to refer to the experience of farm sewage near Glasgow and Ayr—to the southern experience of town sewage at Carlisle, Rugby, and Croydon—and to those particulars of ordinary farm experience which throw light on the subject.—*Gardiner's Chronicle*.

In one ton of cabbage there are 189 ounces of sand, 184 of salt (chloride of sodium), 279 of sulphuric acid, 156 of phosphoric acid, 72 of magnesia, 632 of lime, 208 of soda, 661 of potash.

## Agricultural Intelligence.

### Provincial and State Shows, 1862.

Upper Canada, at Toronto, September 22nd—26th.

Lower Canada, at Sherbrooke, 17th, 18th 19th September.

New York State, at Rochester, September 30 to October 3rd.

Illinois State, at Peoria, September 29 to October 4.

### Soiling Milch Cows.

A correspondent of the Irish Farmer's Gazette says:—"I keep a large number of milch cows, say from 90 to 100, which I house-feed all the year round; in winter on roots, &c., and in summer soiling them with ray-grass, clover, &c. I and my father before me, have followed this practice for the last forty years or more. It has also been our custom to give the soil cut fresh and fresh; that is to say, each feed is only cut a few hours before being given, except the early morning feed, which is cut the evening before, there not being time enough to cut it in the morning. Sunday's feeding has always been cut on that day, as the young grass, if cut the day previous, no matter what care is taken of it, would lose much of its succulent qualities, and be sure to become heated to a certain degree, and so throw the cows off their milk; as I need not tell you how small a change in their feeding will have effect on the milking qualities of cows. We once tried the experiment of cutting Sunday's feeding on Saturday, and the result was a considerable decrease in milk.

**YIELD OF GRAIN IN ENGLAND.**—The Mark Lane Express gives a table comprising the average yield per acre, of wheat, barley, oats, beans and peas, for thirty-eight counties, in England, prepared from returns received from correspondents of that paper. The average for the cereal grains mentioned is as follows:—

|        |                    |
|--------|--------------------|
| Wheat  | 29 bushels         |
| Barley | 37 $\frac{3}{4}$ " |
| Oats   | 46 $\frac{1}{2}$ " |

The lowest average of wheat in any county returned, is 22 $\frac{3}{4}$  bushels per acre, in Devonshire, and the highest 34 $\frac{1}{4}$  bushels in Lancashire. The lowest average of barley is 29 bushels per acre in Shropshire, and the highest 44 bushels, in Northampton. The lowest average of oats is 34 $\frac{3}{4}$  bushels, in Westmoreland, and the highest, 59 $\frac{1}{2}$ , in Cambridgeshire.

The beans mentioned are a kind not much cultivated in this country. The average yield is 32 $\frac{1}{2}$  bushels per acre. The average yield of peas is 30 bushels per acre.

**MICHIGAN STATE FAIR.**—It is announced that the next Annual Fair of the Michigan State Ag. Society will be held at Detroit, Sept. 23d to 25th inclusive—just one week before the New York State Fair. The Society has an able and efficient board of officers, and many enterprising and progressive members, and ought to make a better exhibition this year than ever before, notwithstanding the war. Officers: *President*—J. B. Crippen, Coldwater. *Treasurer*—Philo Parsons, Detroit. *Secretary*—B. F. Johnstone, Detroit. *Members of the Executive Committee*—T. T. Lyon, Plymouth, Wayne Co.; A. S. Berry, Adrian, Lenawee Co.; A. S. Welsh, Ypsilanti, Washtenaw Co.; Geo. M. Dewey, Flint, Genesee Co.; S. S. Bailey, Grand Rapids, Kent Co.; E. S. Moore, Tree Rivers, St. Joseph Co.; U. J. Baxter, Jonesville, Hillsdale Co.; Ira H. Butterfield, Utica, Macomb Co.—*Rural New Yorker*.

**THE CULTURE OF THE SUGAR BEET** is receiving considerable attention at the present time, particularly in the west. The Ohio State Board of Agriculture offers a premium of \$1,000 to the first person who shall have planted, within the State of Ohio, no less than five acres of sugar beets, and manufactured therefrom no less than 5,000 pounds of good, brown sugar, and a specimen of white sugar of not less than 20 pounds in a single uncompressed block.—*Rural N. Y.*

**THE LINDSAY Herald** says that the wheat in the County of Victoria has suffered severely from a grub of a greyish color. The grub not only eats down wheat, but also Indian corn, lettuce, and almost anything that is green. To the wheat crop however, it seems more destructive than to any other, and the damage threatens to be very serious. In Mariposa many farmers are rolling their wheat for the purpose of destroying them. The dry weather has occasioned their unusual depredations.

**CHEAP SUMMER FOOD FOR HOGS.**—The editor of the *New England Farmer* says he has practised the following plan for summer feeding of pigs for many years, and finds it to be an excellent one:—"A few rods of grass plot convenient to the pen is reserved for this purpose, and is mowed by the weekly suds from the wash-room. Commencing at one side of the plot, a large basket of the thick, short grass is mowed each morning while the dew is on, and a part given to the swine at each feeding, three times a day. By the time the last portion of the grass is cut, the first is ready to cut again, and in this way the ground is mowed over many times during the summer, while the grass is kept short, thick, tender and sweet. It keeps the hogs in a healthy, growing condition—they are fed with as much as they will eat every day, and little additional food is needed besides slops from the kitchen."

## Horticultural

### Horticultural Shows this Summer.

Peterborough Horticultural Society, at Peterborough, July 3rd.

Hamilton Horticultural Society, Second Exhibition, July 25th.

Kingston Electoral Division Society, Horticultural Show, at Kingston, July 2nd.

Toronto Horticultural Society, Second Exhibition, July 17th.

### Fruit Growers' Association of Upper Canada.

The next regular meeting of this association will be held at St. Catharines, on Wednesday the 16th day of July, and all gentlemen interested in the subject of fruit growing are invited to attend, and those gentlemen who can not make it convenient to be present will confer a favor by sending in to the Secretary, Mr. D. W. Beadle, at St. Catharines, their answers to the questions proposed by the association and published in the *Agriculturist* for 16th February, 1862.

The meeting will convene in the Town Hall, at 2 o'clock. P. M., and will be in part occupied in discussing and determining the varieties of cherries, plums, and goose-berries best suited to our climate. Members and others are requested to bring with them any specimens they may have of late strawberries, cherries, goose-berries, currants, raspberries, &c., &c. It is expected that there will be a full attendance, and the meeting unusually interesting.

### Apple Tree Borer.

As this insect has occasionally produced very injurious effects on our apple trees in different sections of Canada, we subjoin a description of it from an article in the *Rural Annual* of 1860, and a communication in a recent number of *The Illinois State Agricultural Society*, which with the accompanying wood cuts will be found interesting to our readers.

THE APPLE TREE BORER.

(*Saperda Bivittata*.)

This insect is one of the worst enemies with which our apple trees have to contend. It is a yellowish, footless, cylindrical grub, the larva of a winged-beetle of the *Cerambycidae* family, which makes its appearance in June, and

deposits its eggs, one at a time, upon the bark near the surface of the earth. The maggot, when hatched, eats its way directly down into the bark, producing a discoloration where it is situated. Scraping off the outside bark, the last of August or early in September, so as to expose the white under bark which can be done without injury to the tree, will enable the young worm to be detected and destroyed. *Fitch* says of it: "the worm gradually works its way onward through the bark, increasing in size as it advances, till it reaches the sap-wood. Here it takes up its abode, feeding upon and consuming the soft wood, and forming a smooth, round, flat cavity the size of a dollar, or larger, immediately under the bark. It keeps its burrow clean by pushing its excrement out of a small crevice, or opening, through the bark. This excrement resembles new fine saw-dust, and enables us to readily detect the presence of the worm by the little heap of this substance which is accumulated on the ground, or covers the orifice of the hole out of which it is extruded." The worm when it is about half grown changes its habits, and the cavity, which it was so careful to keep clean and open, it now fills and obliterates, that it may not be discovered. It now confines itself to the heart wood, knowing a cylindrical retreat for itself, upward in the heart of the tree, as shown in the cut of a split section of a tree at this time. Here it lies dormant during the winter season, and in spring changes into a pupa, while still in its hole. From this the perfect insect soon after hatches, and, tearing away the saw-dust like powder which fills up the hole through which the worm originally cleared its burrow, it comes out of the tree. According to *Harris*, the larva state of this insect continues for two years. The tree becomes so weakened by the borer working through the wood, that it is easily blown down by the wind, or knocked down by stoek rubbing against it.

The Apple Tree Borer

It now confines itself to the heart wood, knowing a cylindrical retreat for itself, upward in the heart of the tree, as shown in the cut of a split section of a tree at this time. Here it lies dormant during the winter season, and in spring changes into a pupa, while still in its hole. From this the perfect insect soon after hatches, and, tearing away the saw-dust like powder which fills up the hole through which the worm originally cleared its burrow, it comes out of the tree. According to *Harris*, the larva state of this insect continues for two years. The tree becomes so weakened by the borer working through the wood, that it is easily blown down by the wind, or knocked down by stoek rubbing against it.

The greatest preventative of the undue increase of this insect, is provided in the numerous woodpeckers which inhabit the country, especially the Downy woodpecker. These birds proclaim war to the knife against the borer, and are assiduous in seeking out and destroying it. In

regard to the remedies used by man, in this instance "an ounce of prevention is worth a pound of cure," and for this purpose alkaline preparations of suitable strength, such as soft soap, applied to the outer bark with a brush, are better than anything else. To kill the worm, Fitch recommends finding out, with an awl the top of the burrow, which will probably be not very far from the ground, cutting away the bark there with a pen knife, then scraping out the loose saw-dust and pouring in hot water from a tea-pot until you are certain, from its oozing out at the lower orifice, that the worm is dead. This operation will not hurt the tree in the least.

THE APPLE BUPRESTIS.—(*Chrysobothris femorata*.)

This is another insect, the larva of which has lately been discovered as a borer in our apple trees. The perfect insect is a shiny, blackish-green beetle, belonging to the order of Elaters, or Chick-beetles. It may be observed in June and July, running up and down the trunk and limbs of the tree. Fitch says: "It deposits its eggs on the bark, from which a worm hatches; this worm passes through the bark, and during the first periods of its life consumes the sap-wood, immediately under the bark."—When the worm has become strong, it excavates a burrow in the heart-wood, and makes a great wide hole in the interior of the tree, in which it remains torpid during the winter. In its habits, and mode of procedure, it closely resembles the apple tree borer, already described, and the same remedies that are used against the above borer will probably be found equally effectual with this one. It will be seen by the cut, that this worm differs considerably in appearance from that of the apple tree borer. It is soft and flesh-like, and of a yellowish colour, with a black head, and powerful jaws.

Apple Buprestis.

From the Journal of the Illinois State Agricultural Society.

### Apple Tree Borers.

MR. EDITOR: It is well known to entomologists that there are two distinct "borers" infesting the apple tree. The one in the *larva* or grub state is a whitish, hammer-headed fellow, looking as if he had been squeezed flat between two squares of glass; and in consequence of his front end being about twice as wide as it is high he bores a hole to suit the shape of his head—egg-shaped. The other in the *larva* state is a round or cylindrical whitish grub, and as his front end is round, he bores a *round* hole, not an *egg-shaped* one. He is also when full

grown nearly twice as big as the other chap; and consequently his hole is a good deal larger than that of the other. In the *perfect* or *beetle* state, the *FIRST* is about half an inch long, with rather short horns (or antennæ), and on a cursory view seems quite a brown, dingy affair. A closer inspection, however, will show, that his body above is marked with elegant brassy spots, and that underneath he is all glorious with brass and gold. In the *perfect* or *beetle* state, the *SECOND* insect is about an inch long, with very long antennæ, and he is of a cinnamon color, with two broad milk white stripes reaching all the way from his nose to his tail.

"But" some of your readers will say, "what is the use of knowing all this? What practical advantage is it to know, which of two insects, equally mischievous, and equally hateful, is destroying my orchard?" Not so fast my good friends. We will come to the "practical utility" part immediately.

The first or smaller insect which is a *Buprestis* attacks, as I know from my own experience, not only the trunk of apple trees, either at top, middle, or butt, but also small limbs, not over three-quarters of an inch in diameter. The second or larger insect, which is a *Saperda*, generally confines his attack to the *butt* of the trunk, pretty close to the ground. Instances are known indeed of his attacking the trunk in the crotch, or where it branches out into limbs, but such instances are rare, and generally occur only where the parent beetle finds the butts of all the trees pre-occupied, and so takes to the crotch for want of its favorite locality. Small as insects are, they know a great deal. For instance, they all know enough to make good provision for their future families, which is more than some two-legged bugs that wear coats and pantaloons always know. Now I stated in my essay on "Insects injurious to vegetation in Illinois," (printed in your transactions, vol. 4, p. 345) that Dr. Fitch, the state Entomologist of New York, had proved by a decisive experiment that a certain preventive against the attacks of the *Saperda*, or big round borer, was "to rub the bark of the trees with soap the latter part of May each year;" but that whether the soap was equally effectual against the little hammer-headed borer (or *Buprestis*) remained to be proved. I have a small garden in Rock Island about the size of a pocket handkerchief, in which I planted, some years ago, a dozen apple trees. In the spring of 1851 I dug out of these trees probably over a dozen borers of the hammer-headed headed kind, and having great faith in soap, about the last of May, 1861, I applied Dr. Fitch's preventive to all of them. To be plain and explicit, I took a bar of the newest and softest soap I could get (value ten cents,) and with this I thoroughly rubbed over all my trees, not only to the trunks, but also such limbs as were three-quarters of an inch through. The result this spring (1862) is, that

there is not a borer to be found in any of them and I give the facts, just as they are, to your readers for what they are worth. Of course, it would have been more satisfactory to have soaped half the trees, and left the other half unsoaped, as Dr. Fitch did; and then if the soaped trees had been free from borers and the unsoaped trees full of them, the proof would have been pretty conclusive. But Dr. Fitch is paid by the state of New York for conducting such experiments as these, and therefore can afford to make them; we western bug-hunters on the other hand, who have to foot our own bills, cannot afford to sacrifice our own private and peculiar apple trees for the benefit of the public.

Now for the "practical utility" part. Look at your apple trees, and see if you can dig any borers out of them, and what shape and size those borers are; and if not, see if you can see the holes where the insects have formerly eaten their way out. If the holes are oval and rather small, say the 3-16ths of an inch, and not confined to the butt of the trunk, you may know it is the *Buprestis*; if the holes are larger, and say the size of a smallish pea, and found exclusively in the butt, you may know it as the *Saperda*.

In the former case, if you have faith, as I have, in the "soap remedy," you must soap not only the trunk of the trees, but the small limbs; in the latter case it is sufficient to soap the trunk, and if you are driven for time and soap is dear with you, probably it would answer to soap the crotch and the butt end of the trunk alone. *A word to the wise is sufficient.*

BENJ. D. WALSH.

### Improvement of Grounds.

The following valuable article on a subject of great interest to all who own the soil on which they live, whether in country or village, is by A. J. DOWNING:

"Pleasure and profit are certain, sooner or later, to awaken a large portion of our countrymen to the advantages of improving their own private grounds. But we find it is only under two conditions that many public improvements are carried on. The first, is when nearly the whole of the population enjoy the advantages of education, as in New England. The second, is when a few of the more spirited and intelligent of the citizens move the rest by taking the burden in the beginning upon their own shoulders by setting the example themselves, and by most zealously urging all others to follow.

"The villages of New England, looking at their sylvan charms, are as beautiful as any in the world. Their architecture is simple and unpretending—often, indeed, meagre and unworthy of notice. The houses are surrounded by enclosures full of trees and shrubs, with space enough to afford comfort, and ornament enough

to denote taste. But the main street of the village is an avenue of elms, positively delightful to behold. Always wide, the over-arching boughs form an aisle more grand and beautiful than that of any old gothic cathedral. Not content, indeed, with one avenue, some of these villages have, in their wide, single street, three lines of trees, forming a double avenue, of which any grand old palace abroad might well be proud. Would that those of our readers whose souls are callous to the charms of the lights and shadows that bedeck these bewitching rural towns and villages, would forthwith set out on a pilgrimage to such places as Northampton, Springfield, New Haven, Pittsfield, Stockbridge, Woodbury, and the like.

"When we contrast with these lovely resting places for the eye, embowered in avenues of Elms, gracefully drooping like fountains of falling water, or Sugar Maples swelling and towering up like finely formed antique vases, some of the uncared for towns and villages in our own State, we are almost forced to believe that the famous common schools of New England teach the aesthetics of art, and that the beauty of shade trees is the care of especial professorships. Homer and Virgil, Cicero, Manlius, and Tully, shades of the great Greeks and Romans!—our citizens have named towns after you, but the places that bear your names scarcely hold leafy trees enough to renew the fading laurels round your heads!—while the direct descendants of stern Puritans, who had a holy horror of things ornamental, who cropped their hair, and made penalties for indulgences in fine linen, live in villages overshadowed by the very spirit of rural elegance!

"It is neither from a want of means, or want of time, or any ignorance of what is essential to the beauty of body or of mind, that we see this neglect of the public becomingness. There are numbers of houses in all these villages, that boast their pianos, while the last Paris fashions are worn in the parlors, and the freshest periodical literature of both sides of the Atlantic fills the center tables. But while the comfort and good looks of the individual are sufficiently cared for, the comfort and good looks of the town are sadly neglected. Our education here stops short of New England. We are slow to feel that the character of the inhabitants is always, in some degree, indicated by the appearance of the town. It is, unluckily, no one's especial business to ornament the streets. No one feels it a reproach to himself, that verdure and beauty do not hang, like rich curtains, over the street in which he lives. And thus a whole village or town goes on from year to year, in a shameless state of public nudity and neglect, because no one feels it his particular duty to persuade his neighbors to join him in making the town in which he lives a gem of rural beauty, instead of a sorry collection of uninteresting houses."

### Fruit Trees in the West,

The *Wisconsin Argus*, with the text, "the failure of Fruit Trees," discusses the question of fruit growing in the West as follows :

It is notorious that, in this State, most varieties of apple trees, after growing finely for a few years, just as they begin to bear, begin to die ; and after lingering two or three years, perish entirely. This mortality is, we believe, confined to the grafted trees. The defection commences in the *body* of the tree at various points, but most usually near the lower branches, and spreads in both directions, till the main branches, one after another, are deprived of nourishment and die.

Various remedies have been tried, the most successful of which is similar to the one devised by a certain wight for keeping the squirrels from destroying the corn: He had noticed that they always took the *outside row*, and his plan was not to have any outside row ! As the disease affects the *body* of the tree, the remedy is, *not to have any body*, but let the limbs come out as near the ground as they will—within two or three feet at the farthest. It is well known that trees of the same variety, thus grown, will succeed and live, while those trimmed up for a long body will die.

It is difficult to understand what can cause the difference, unless it be that low branches keep the short trunk shaded and less exposed to extreme variations of the temperature. This explanation receives confirmation from two considerations, viz: the defection always takes place upon the *south-west side* of the trunk ; and that is the side exposed to the sharpest cold in the winter and the most scorching heat in the summer. If we have here a clue to the cause of the difficulty, the question arises whether the disease is produced by the piercing south-west winds in the winter, or the scorching afternoon suns in the summer, or from the alternating extremes of the two. A little range of observation may aid our conjectures upon this point.

Upon the island of Mackinaw we have seen apple trees, of considerable age and in full bearing, remain sound and healthy, though as to the varieties we could not speak with certainty.—This would indicate that it is not the *cold* which does the mischief.

In South Carolina, Georgia and Alabama, peach trees, if left unprotected, perish precisely in the same way that apple trees do in Wisconsin. The bark dies, the wood cracks open, and the whole south-west side perishes, and the defection works round till there is nothing but a narrow strip of life left upon the north-east side ; and this soon yields to the influence of the dead portions of the tree. The destruction of the peach tree in those regions is well known to be caused by the intense heat of the sun in the after part of the day ; and the remedy

there is, to take a piece of board, about eight inches wide, and long enough to reach from the ground to the limbs ; sharpen one end, and drive it into the ground, leaving it to stand within six or eight inches of the body of the tree on the south-west side. In well managed peach orchards in those States, every tree is protected in this way ; and whenever one is neglected, it presents exactly the appearance of a half dead apple tree in Wisconsin ; while trees thus protected, remain sound and healthy.

It is affirmed by some intelligent fruit growers in Wisconsin, who have paid much attention to the subject, that there are varieties of choice grafted fruit that will stand the climate ; but we do not consider this fully demonstrated, and would suggest the simple precaution practised by our Southern brethren with their peach trees. A dime's worth of lumber will protect a tree for several years."

### Growing Double Flowers.

We cannot explain all that a correspondent would like to know about Double Flowers—why they become double, &c.; nor can we tell from the appearance of a seed whether it will produce double or single flowers. It seems to be admitted, generally, that seeds that have been kept a number of years, will produce more double flowers than if sown the first season. In this opinion our correspondent is supported by good authority, yet we have always doubted whether there is any good reason for the belief. On this subject we give an extract from a volume of the *Revue Horticole* :

"It is impossible for any inquiring mind not to attempt an explanation of the fact that many plants which, in a state of nature, never present more than a single row of petals, begin to assume several rows under continued cultivation. The effects of a richer soil, and other genial circumstances, or the mere accident of double petals in one plant, transmitted with improvement through its progeny, are the common explanations ; and they are generally received as satisfactory, without reflecting that what we call accident is itself a result of some cause, and that change of condition must attack some physiological principle before it can have any effect in modifying the character of a plant. Nothing is now so common as double flowers ; and to explain the phenomenon, we must make practice agree with theory. Every gardener who sows seed wishes to obtain plants with double flowers, so as to have blossoms which produce the greatest effect. Every double flower is a monstrous vegetable. To produce this anomaly, we must attack the principle of its creation—that is to say, the seed. This being granted, let us examine in what way these seeds ought

to be treated. If, after having gathered the seeds of Tenweeks' Stock, for example, we sow them immediately, the greater number of the seedlings will produce single flowers; while, on the contrary, if we preserve these same seeds for three or four years, and sow them, we shall find double flowers upon nearly all the plants. To explain this phenomenon we say, that in keeping a seed for several years we fatigue and weaken it, so that the energy which would otherwise have been expended in producing stamens, produces petals. Then, when we place it in a suitable soil, we change its natural state, and from a wild plant make it a cultivated one. What proves our position is, that plants in their wild state, shedding their seeds annually, and sowing them as soon as they fall to the ground, yet in a long succession of time scarcely ever produce plants with double flowers. We think, then, after what we have said, that whenever a gardener wishes to obtain double flowers, he ought not to sow the seeds till he has kept them for as long a time as possible. These principles are equally applicable to melons, and all plants of that family. We admit, like many observers, that melon plants, obtained from seeds the preceding year, ought to produce, and do produce, really very vigorous shoots, with much foliage; but very few fruitful flowers appear on such plants; while, on the other hand, when we sow old seed, we obtain an abundance of very large fruit. In fact, in all varieties of the melon, the seeds should always be kept from three to eight years before being sown, if we would obtain fine fruit and plenty of it."

We have kept Balsam and Tenweeks Stock seeds for ten years, sowing some every year, and we could not discover any improvement by age in any respect. Much more depends upon the manner in which the plant that produces the seed is grown than upon its age. The idea of the seed being fatigued or weakened by age so as to produce double flowers, seems to us very much like nonsense. What we want to produce good flowers, is short, stocky plants. If the plants become drawn when young, the flowers, as a general thing, will be worthless.—*Rural New Yorker*.

**RIBAND FLOWER BORDERS.**—The riband system is now very generally practised, and where a border admits of sufficient length and width, a most effective display may be created by planting, say—1st row, *Cerastium tomentosum*; 2d row, Purple Verbena; 3d row, Variegated Geraniums; 5th row, Bedding Dahlia, *Alba floribunda nana*, planted in a sloping position so as to keep it dwarf. Such a riband can be very much varied by using White Verbena, Blue Lobelia, purple Zelinda Dahlia, Yellow Calceolaria, and many other plants, always avoiding, if possible, bringing a bright scarlet and a yellow

close together. Very effective beds may be planted with Blue Ageratum, bordered with Lemon Calceolaria; Maroon, or Purple Verbena, with the Silver Cerastium; Yellow Calceolarias, with Cattels' Orange Scarlet Nasturtium, or *Gazania splendens*; Variegated Geraniums with Scarlet Geraniums, or *vice versa*; Blue Lobelia with the Silver Cerastium or Variegated Alysium; *Gazania splendens* with Blue Lobelia; White Verbena with Scarlet Verbena, or *vice versa*; Pink, Rose, Maroon, or Crimson Verbena; Alba Floribunda Dahlia with Purple Zelinda Dahlia; *Tropæolum Lobbianum elegans* with Silver Cerastium; Scarlet Geranium or Crystal Palace Scarlet Dahlia with Silver-Leafed Cineraria; Heliotrope with variegated Mint. In fact, so many different and pleasing arrangements may be made in regard to the plants named, that we do not consider it necessary to detail them here, as they will readily suggest themselves to those who bestow a few moments' thought on the subject. Bordering beds seldom answers, if the beds are very small. The border, to be effective, should be about one-third the diameter of the bed.—*Scottish Horticulturist*.

**STRAWBERRY CULTURE—STIRRING THE SOIL.**—At a late meeting of the Brooklyn Hort. Society, Mr. Fuller said that he had grown at the rate of 600 bushels per acre, on a small plot of the Bartlett strawberry, and by the same mode of treatment, 400 bushels of Triomphe-de-Gand. The best treatment I have ever given strawberries when grown in hills, was to stir the surface a little every day. Some varieties grow best in stools, the Wilson, for instance, and others do best when they all run together. I have great faith in lightly stirring the soil among strawberry plants. The best Delaware grape vines I ever grew I produced by stirring the soil regularly every Saturday evening, with a rake, and I believe it would pay to rake the ground among the strawberry plants every day, and cut off all the runners. I can grow strawberries by this process upon poor soil, without manure. I am satisfied that surface soil stirring is the most important of all modes of cultivation. But in a strawberry bed you must be careful not to dig too deep. There is no process that can be applied to the cultivation of cabbage and cauliflower, equal to stirring the surface every day."

**RENEWING PEACH TREES.**—Peaches are never borne twice on the same wood, but always on the new wood of the previous summer's growth; hence peach trees soon get beyond our reach, if not cut back, or "summer pruned." The bearing wood each year gets farther from the ground, until we only find a little fruit on the ends of the branches. Mine were in that condition in the spring of 1861, when, as the sudden cold snap of November, 1860, destroyed all the fruit

buds, so there would be no fruit for the trees to nourish in the summer of 1861, the growth of wood would be very great, and the trees still farther beyond control. To subdue them, I sawed them off about two feet from the ground, in April, and covered the wounds with gum shellac, (not a good article;) a mixture of one-third each of beeswax, rosin, and tallow is a much better covering. They all pushed out numerous shoots, which grew from 5 to 8 feet in length, and every twig is full of fruit buds, so that I have a good prospect of a crop the coming season, unless the mercury falls to 8 or 10 below zero, a degree of cold the peach blossom bud cannot stand in this section.

The conclusion arrived at is this: with the treatment named, (barring the excessive cold,) a crop of peaches can be obtained every year, by sawing down every other tree in the row, or alternate rows, every year. Let half the trees be producing wood and the other half fruit, and the following spring saw down those that had fruited.

Should the frost kill the fruit-buds, then saw all back to the stump again.

The method of cultivating low gives us control of the trees, to thin out fruit, cut back, or summer prune.—*J. C. Thompson in the Horticulturist.*

### The Cultivation of Wild Flowers.

Those who wish to cultivate flowers, yet cannot well afford to purchase them, and others, also, who would add some native growing varieties to their fine parterres of rare and important plants, may find in our woods and fields many beautiful kinds well worthy of removal and careful cultivation. Foremost of these in simple loveliness, are the white, blue, and yellow Violets; they are readily transplanted, and when arranged in large beds or borders, are exceedingly effective, growing much larger and longer-stemmed under garden culture, than in their native haunts.—Then, there are the Anemones, with their tender white or pinkish flowers, threaded with crimson. These, also, grow finely in large patches, and may be transplanted either in the spring or early autumn. The writer has succeeded in transplanting many kinds of wild flowers, even while they were in full bloom, by keeping them well watered and carefully shaded for the first ten days.

For extreme richness of colour, the Scarlet Lobelia (*Lobelia cardinalis*) is unequalled. This is very easily cultivated, and, under the gardener's care, throws out its vivid flowers in grateful profusion. The native Asters are susceptible of great improvement under garden culture. Then there are the Gentians, the wild Honeysuckle, and the Climbing Cle-

matic, all hardy and graceful; and, among shrubs, the Laurel with its waxen clusters peering from branches of glossy green—the most exquisitely-wrought of all the wild flowers.

The Lilies, Lupins, Sweet Briars, Geraniums, Iris and Hepaticas, are well worthy of a place in the flower garden. The Dragon Root (*Arum triphyllum*) is extremely graceful, and grown in large patches, as the writer has seen it, has the effect of some rare tropical plant. The Yellow Snakeleaf or *Erythronium*, is very pretty with its long green leaves, spotted with red, and its delicate bell-shaped flowers, and in many localities is the earliest vernal flower we have. Like most wild flowers, it requires to be kept very moist when first transplanted, and completely shaded from the sun's rays.

The list given above, of wild flowers susceptible of garden cultivation, is necessarily incomplete—their name is legion—and in no book yet written, can a complete catalogue of Nature's floral treasures be found. On her own glowing page, lying invitingly open to the hand and eye of man, each may find for himself an endless variety; and by observing the habits and localities of the various kinds, there need be no difficulty in adapting soil and treatment to their wants. Some are found nestling deep in the shadow in the wood, some, more light-loving, cluster in the fields and along the roadside; some love the ponds and brooks, and bloom amid the tall grass on the banks, and some climb the mountain side and hang their graceful festoons across the jagged rocks. In each and all there is beauty, and Nature, in her prodigality and consciousness, will not begrudge us a few to nurse and tend in our gardens. We can never make them appear half as beautiful as they do in their original surroundings—for the Gentian on our faultless trellis, fuller in its flower, and richer in its dye, is still but the city sister of the blue-eyed Gentian, climbing up the rocks—but we can turn them into very respectable garden flowers, "improved" and "double," if we wish—and certainly we will find them well worth the trouble.—*Working Farmer.*

ROSE LEAF PICTURE FRAME.—A writer in *The Home and Garden* thus describes how to make a pretty, ornamental style of picture frames:—"The leaves of the multiflora or climbing rose, are best suited for this purpose, as they have a greater richness and variety of colour than most of the rose family. At the time when there is the greatest variety of coloured leaves, strip them from the bush, and put them to press in any old book you do not wish to use; change them as often as every other day, until sufficiently dried; then take any picture you wish—an engraving is gener-

ally used—fasten it on to a paste-board, and leave a margin of the width you wish for your frame, outside the engraving. Sew the leaves on to the paste-board frame, either in knots or groups, or simply overlapping each other, and varnish with furniture varnish. When dry, suspend with cord and tassels, and you have a very pretty picture-frame." Other leaves of variegated colours, as maples, &c., or several sorts showing different shades of green, may be used in the same manner.—*American Agriculturist*.

### Indoor Gardening.

One of the prettiest ways of having flowers in rooms is perhaps the fashion of little hanging baskets. In flower stands and on tables, and even in boxes, it is often difficult to arrange climbers nicely; they either require height in the way of trellises, which we find it hard to give, or they droop down in an ungraceful fashion. In the use of hanging baskets neither of these things happen. The climbers may if they like twine up the wires or cord, or they may still more prettily droop down over the basket. One of the prettiest things for this is the little *Campanula*, its bright blue flowers trail down neatly and yet closely into a lovely carpet, and if in the midst we place a pretty fern, its fronds wave over and make quite a perfect centre. I was told the other day that the *Adiantum cuneatum*, one of the very loveliest sorts of Maiden Hair, did well for such a purpose, and this would be, I think, the prettiest kind to try; although it is a stove fern it has been kept for years in a room window, and, in fact, it seems one of the most easy of its class to manage.

The wild pink geranium is another delightful and very aromatic basket plant, and the little blue *Lobelia* and the beautiful *Torenia asiatica* are also amongst those which droop down gracefully and show their beautiful blue flowers.

In arranging these baskets the grand thing, I think, is to give enough drainage. I always put broken charcoal, covered with a thin layer of moss, adding afterwards the soil that the plants require, and the charcoal occupying a space of perhaps 2 inches, a little water generally collects there. Any one used to watering these baskets soon comes to know by weight if they are dry or wet; and if by any chance one morning the soil should seem still moist, the daily watering ought to be then omitted.

Common black hair-pins are excellent pegs to use for fastening down the runners of creeping things, when we want not to show a quantity of sticks, and for tying up window plants the narrow dark green ribbon often used for book marks is the best and neatest substitute for bass when a thin stripe of it is not found suitable. I have often tried tying up plants with worsted, but

that holds water too much and is also untidy looking, and threads of netting silk, though invaluable for trainers (on which the plants twine themselves), are too apt to cut the stems to be safe for tying.

Any baskets that are to be hung up ought to be fitted with an inner lining to contain the roots, and this should be surrounded by something calculated to prevent over dryness to it. I do not generally like wire stands for plants; but when they are used, and when some means is found of protecting the pots sufficiently, they may be made really beautiful by pink and white and blue *Ipomœas* climbing all about them. The different varieties of *Quomoclit* I think are the best to use for this, with the exceedingly pretty "rubro-cœrulea," which I have often grown, and consider a charming annual. It will not, however, bear a great deal of sun, and is especially injured by the hot summer rays striking upon the stem or collar when it is exposed. In placing it in a window box I therefore always manage to have some plant in front of it to give a little shelter. *Mignonette* thus proves a capital foster nurse to a great many plants.

The wire stand that I had last year was one of those in steps—three on each side, and a wide shelf beneath. Very green and spreading *Ipomœas* were placed in the lower steps, roses, or geraniums, or fuchsias, in the others, and two or three more *Ipomœas* with *mignonette* below. The leaves and tendrils entwined themselves most gracefully round every wire, and ran round every edge, while the varied flowers that opened every morning and closed up at night looked extremely gay. Each of these pots of climbers contained several plants—the pots were 32's and the soil leaf mould. They required generally very abundant watering at the roots; indeed, a day's dryness at any time caused some of the leaves to assume a yellow and faded look.—*E. A. M., in Gardener's Chronicle*.

### Domestic.

#### Approved Domestic Receipts.

\* GINGERBREADS, PIES, JELLIES, &c.

*Soft Molasses Gingerbread*.—Mix with a pint of molasses, a teacup of melted butter, a pint of flour, 2 eggs well beaten, spoonful of ginger dissolved in a tumbler of milk, and stir in 2 teaspoonsful of saleratus; add flour to make it stiff as pound cake; bake half an hour.

*Hard Gingerbread No. 1*.—Rub half a pound of butter into a pound of flour, then rub in half a pound of sugar, 2 teaspoonsful ginger, 1 spoonful rose water; mix it well, roll out, bake in flat pans in a moderate oven half an hour.

*Hard Gingerbread No. 2*.— $3\frac{1}{4}$  lbs sugar, 2 lbs flour, 3 eggs, half pound butter, 1 teaspoonful saleratus, 2 spoonfuls ginger or nutmeg, wet with half cup of milk.

**Circle Gingerbread.** 2 cups of milk, (sour if you like), a cup of molasses, 1 of sugar, 1 of butter, 2 eggs, 5 heaping teaspoonsful of saleratus, flour enough to make it stiff as pound cake, essence lemon, and nutmeg.

**Hard Gingerbread.** 1 cup of butter, 1 of sugar, 3 eggs, 1 nutmeg, or ginger, a small teaspoonful of saleratus dissolved in a little milk; as little flour as will roll it out well.

**Alum Gingerbread.** 1 cup molasses, 1 of milk, half cup butter, 1 teaspoonful alum, 2 of soda, large spoonful ginger, flour enough to roll out, bake in sheets.

**Good Gingerbread.** 1 cup molasses, 1 of milk or water, 2 eggs, half cup butter, 1 teaspoonful saleratus, 1 of cream tartar, nutmeg or spice to taste.

**Gingerbread.**—1 cup sugar, 1 of molasses, half cup of milk, 1 cup butter, 2 eggs,  $3\frac{1}{2}$  cups of flour, half teaspoonful of saleratus, ginger to to your taste.

**Sugar Gingerbread.**—2 cups sugar, 1 of butter, 1 of milk, 1 egg, 1 tablespoonful of ginger, 1 teaspoonful of saleratus, flour enough to roll.

**Gingerbread.**—2 cups molasses, 1 of butter, 2 eggs, 1 cup sweet milk, 5 cups flour, 2 teaspoonfuls soda, 1 teaspoonful ginger.

**Molasses Gingerbread.**—1 cup molasses, 1 cup milk, 2 eggs, butter size of an egg, 1 spoonful of saleratus, flour and spice.

**Sugar Gingerbread.** 1 cup butter, 2 cups sugar, half cup boiling water, tablespoonful ginger, 1 of saleratus.

**Muffins.** 1 pint of warm water, 1 egg, half cup sugar, half cup of yeast, half teaspoonful saleratus, a little salt, flour enough to make a stiff batter; mix at noon and fry in morning.

**Muffins.** 4 cups of flour, 2 of milk, 1 egg, 2 tablespoonfuls of sugar, 2 teaspoonfuls cream tartar, 1 of soda; bake in a quick oven.

**Muffins.** 1 pint of milk, 1 pound of flour, 3 eggs, half cup yeast.

**Doughnuts.** 2 cups white sugar, 3 eggs, 2 cups milk or water, piece of butter size of an egg, 1 teaspoonful cream tartar, 1 of saleratus, 1 nutmeg, a little allspice.

**Doughnuts.** 2 cups sugar,  $1\frac{1}{2}$  cup milk, 3 eggs, 1 teaspoonful saleratus, piece of butter size of a hen's egg; roll very soft.

**Doughnuts.** 1 cup of sugar,  $1\frac{1}{2}$  of milk, 1 egg, small piece of butter, 2 teaspoonfuls cream tartar, 1 teaspoonful soda, spice to taste.

**Doughnuts.** 2 cups of sugar, 1 cup butter,  $1\frac{1}{2}$  cups sour milk, 5 eggs, half cup sweet milk, one teaspoonful of saleratus.

**Buckwheat Cakes.** Mix one quart of buckwheat flour with 1 pint of lukewarm milk or water, half cup of yeast, and set it in a warm place to rise. When light, which will be in eight or ten hours, add 1 teaspoonful of salt, and if sour, 1 teaspoonful saleratus dissolved in a little milk; if too thick, thin them with just

sufficient cold milk or water; fry in enough fat to prevent sticking to the pan.

**Little Plum Cakes that keep long.** 1 pound flour, mix with 6 ounces sugar, beat 6 ounces butter to a cream, add 3 eggs well beaten, half pound currants, the plums and sugar; beat all half an hour, then drop the butter on tins or buttered paper size of a walnut; bake in a brisk oven.

**Rye Drop Cake.** 1 pint of milk, 3 eggs, 1 tablespoonful sugar, little salt, stir in rye flour till it is as thick as pan cakes. Bake in buttered cups or saucers half an hour.

**Mince Pies.** 3 pounds chopped meat and suet, 6lbs. chopped apple, 1 lb. raisins, little more than 1 quart molasses, more than 1 quart cider, 1 cup spices.

**Lemon Pie.** 2 lemons, 3 crackers, 2 eggs, 3 cups sugar, 1 of water, small piece of butter. This will make three medium sized pies.

**Lemon Pie No. 1.** 4 lemons grated, all but the rind of two, 3 cups sugar, 3 eggs, all beaten together will make three pies.

**Lemon Pie No. 2.** The juice of 1 lemon, 1 pounded cracker, 1 cup sugar,  $2\frac{1}{2}$  cups water.

**Lemon Pie No. 3.** 1 lemon,  $1\frac{1}{2}$  cup sugar, 2 eggs, 2 spoonfuls cream, 1 cup flour.

**Lemon Pie.** 1 lemon, 2 eggs, 2 spoonfuls cream, 1 spoonful flour,  $1\frac{1}{2}$  cups sugar.

**Nice Dish for Breakfast.** Beat 1 egg, add one teaspoonful salt, pour in about two-thirds of a pint of water, slice some bread, dip it in, and fry in a little butter. Serve warm.

**Brown Bread, or Togos Cake.** 3 cups Indian meal, 1 of flour, 3 of sweet milk, 1 of sour milk, half cup molasses, small teaspoonful soda, steam three hours, (bake 20 minutes;) half teaspoonful of ginger improves it.

**Brown Bread.** 1 cup sour milk,  $3\frac{1}{2}$  cups of meal, 1 of rye, 1 of molasses, 3 of sweet milk, 1 teaspoonful salt, 1 of saleratus. If large cups, steam 4 hours and bake 2.

**Icing for Cake.** White of 1 egg, 9 teaspoonfuls sugar, 1 of starch.

**Ginger Snaps.** 1 cup butter, 2 of sugar, half cup milk, (sour if you have it,) 1 teaspoonful ginger, half teaspoonful soda.

**Cookies.** 1 cup of butter,  $1\frac{1}{2}$  of sugar, 4 eggs,  $2\frac{1}{2}$  cups of milk, 1 teaspoonful saleratus; melt butter, put the sugar to it; do not beat the eggs.

**Kisses.** Half pound of sugar and the whites of four eggs, beat to a froth, mixed and flavored with rose; put in the oven on a board covered with white paper, drop with a teaspoon on the paper and bake light brown, then slip them off with a knife, and stick two together.

**Charlotte Russe.** Half box gelatine; dissolve in 1 coffee cup of milk; cooled, add 1 pint

of cream, whites of seven eggs, beat to a hard froth, 1 cup sugar; line the mould with sponge cake, pour in the jelly, set away to cool; when served, turn on to a flat dish—vanilla.

**Italian Cream.** Take 3 pints of milk or cream, sweeten it with white sugar, flavor with vanilla or lemon. add 1 paper of gelatine; stir constantly until it boils; beat well the yolks of 8 eggs, stir them well into the boiling cream, strain into moulds, stand on ice 5 or 6 hours; to be served with cream and sugar.

**Yeast.** 3 potatoes, washed clean and put into 1 quart of water, with half a pint of dry hops, boil together till the potatoes are done then peel and wash; one third of a cup of salt, half cup sugar,  $1\frac{1}{2}$  cup flour, mix with the potatoes, strain the hops when hot upon the above—strain the whole through a calender, when milk-warm, add a cupful of yeast, and put to rise, after which put down cellar; to 1 quart of water two-thirds of a cup of yeast is suitable to raise bread.

**Potato Yeast.** Take 6 good sized potatoes, boil them in 2 quarts of water; when well done, take them out and mash them fine. Then put them back into the water, and add a handful of hops. When well boiled, strain it through a sieve into a little thickening, a tablespoonful of flour, a cup of sugar, half cup of salt; if you mix the bread with water a little shortening will improve it; if you use milk, it is not necessary.

**Wine Jelly.** To one-half of a 25 cent box of gelatine add 1 pint of cold water. the rind of 1 lemon cut, not grated, juice of 2 lemons; let it stand for an hour and a quarter, take out the lemon rind and add a little less than  $1\frac{1}{2}$  pint of boiling water,  $1\frac{1}{4}$  lbs. sugar, a good half pint of wine, then pour into moulds; straining is hardly necessary; stiff in 4 or 5 hours.

**Wine Jelly.** 1 box of gelatine,  $1\frac{1}{2}$  pint boiling water, 1 pint sugar, 1 stick cinnamon, 1 lemon, 1 pint of wine; stir the ingredients together and then strain it.

**Currant Jelly without Boiling.** Squeeze the currants through a thin cloth, take a pound of sugar to a pound of juice, rub sugar into juice with hands, set it in the sun 2 or 3 days.

**Currant Jelly.** Wash the currants, then squeeze them through a thin cloth; to 1 pint of juice add 1 pound of sugar; heat the juice well, then put in the sugar and boil about 15 minutes; strain and put in cups.

**Apple Jelly.** Quarter the best quality of apples and stew till soft; strain out the juice, boil it to the consistency of molasses, then weigh it and add as many pounds of crushed sugar, stirring it constantly till the sugar is dissolved; add 1 ounce of extract of lemon, to every 20 pounds of jelly; when cold set it away in close jars; it will keep good for years.

**Crullers.** Dissolve a teaspoonful of saleratus in four tablespoonfuls milk, or leave out one spoonful of milk and substitute one of wine; strain it in o half a pint of flour, 4 tablespoonfuls melted butter or lard, and a teaspoonful of salt; beat 4 eggs with 6 heaping tablespoonfuls of rolled sugar; work them into the rest of the ingredients, together with a grated nutmeg; add flour to make them stiff enough to roll out easily—about an inch thick.

**Crullers.** 4 eggs, 3 cups sugar, butter the size of an egg, 4 large spoons of milk, 1 salt spoonful saleratus, nutmeg or lemon, salt; roll out hard.

**Sauce.** 2 eggs well beaten, 9 teaspoonfuls sugar, a little butter and flour; pour boiling water upon it; butter and flour together; sugar and eggs together.—*Mvine Farmer.*

### Recipes for Hard and Soft Soap.

A correspondent in the *German town Telegraph* offers the following recipe as one to be perfectly relied on:

Take ten pounds of soda ash, and dissolve it in twenty gallons of soda water, with twelve pounds of fresh lime and three-fourths of a pound of rosin, by boiling them all half an hour, stirring the while to keep them from setting or burning; then pour all the contents into a tub to settle, washing your kettle clean. After these contents have settled, take the clear water that comes on the top and put it in the kettle; now hunt up all your fat and skins till you get about twenty-three pounds—if clear fat not quite so much—put over the fire to boil till all the fat is eaten up; perhaps it will take two hours, or not nearly so long; then take fine salt to divide, and add salt till the hard soap comes on the top. It will at first look like froth, and the waste will look very dark in the bottom of the kettle. Pour all out in a tub. I forgot to say, fill up your tub with cold water after taking on the first clear lye, ready to boil your soap froth with the second time; put two good bucketsfull of this clear lye in the kettle, then with an iron ladle take all this soap froth off the top of the tub and put it in with these two buckets of lye-water, to boil again a few minutes, to make your hard soap clear and nice, adding salt till it separates well. Then pour all over in a tub, to remain undisturbed over night. In the morning you will have over thirty pounds of as white soap as you will wish, for either washing or toilet use, which will not chap the hands at any time. Again, if you would wish a half barrel of nice white soft soap, fill up this said lime tub again with cold water till it settles, then take the hard soap that sticks to the kettle and the pitcher that you dip out with, and three or fourth ladles full of your hard soap, with two pitchers full of this lye-water, and let it boil a

few minutes till it looks like soap, then fill up your kettle nearly full of the lye-water, and let boil a few minutes, then pour it into a vessel, and you will be much pleased with the result of your labor. This soft soap will be thick and solid, and it is very nice for boiling clothes or washing as it makes a very nice froth.

In order to have plenty of soap fat, you must begin at the beginning to save all the skins of meat, and all the fat scraps that come from your table, which in warm weather, should be put in some of this clear lye until you get enough to make some soap. By this course, in an ordinary family, you will always have enough soap without buying.

### Killing Rats—A Novel Trap.

The premises of a good many farmers are often infested with rats, and we are often asked for modes of destruction. A resident of Brooklyn is vexed with an increasing family of rats that seem to grow fat on arsenic and rat exterminators. He doesn't like rats, and refers his case to the *Sunday Times*. That journal recommends a trap made as follows:

"Take a mackerel barrel, for instance, and fill it to about one-third its height with water. Then place a log endwise in the water, so that one end of it will just remain above the surface. Make the head of the barrel a little too small to fit, and suspend it by two pins to the inside of the top of the barrel, so it will hang as if on a pivot and easily tip by touching either side. On this head, thus suspended, secure a piece of savory meat. The first rat that scents it, will, to get the meat, leap on the barrel head. The head will tip, or tilt, and precipitate him into the water, and resume its former position. The rat in the water will swim to the log, get on the end of it, and squeal vociferously. His cries will bring other rats, all of whom will be tilted into the water, and all of whom will fight for the only dry spot in it—viz., the end of the log. As only one rat can hold it, the victor will drown all the rest, and can, in the morning be drowned himself. We have seen twenty rats caught in one night by such a trick.

**How to Cook Eggs in the Shell.**—A correspondent of the *Agriculturist* writes:

One way to cook eggs is to drop them into boiling water, and let them remain there three minutes—the water all the time boiling. This hardens the white next the shell to almost leathery toughness, while within it is still not cooked. Another and preferable mode is, to pour boiling water upon the eggs; let them stand five minutes; pour off this, and add more boiling water, and immediately bring them to the table in the water. Those taken out at once will be somewhat cooked through; and those left in five minutes will be "hard boiled," or nearly so, and thus the taste of every one may be suited, and no toughness of the whites be observed.

## Veterinary Department.

(Conducted by A. Smith, V. S.)

### Sore Shins.

This is a disease affecting both the fore and hind shank bones of horses, and of most common occurrence in race-horses. It arises from inflammation set up in the periosteum or covering of bone, and as a consequence there is an effusion of the lymph between the bone and periosteum, also on the surface of this membrane. A diffused tender swelling rises on the front of the shank bone, by-and-by ulcers form on the skin from which matter freely exudes. The outer surface of the bone dies, shells off and comes away in small pieces, and if recovery takes place new bone forms underneath.

The reason that this disease most commonly occurs in well bred fast young horses, can be accounted for thus:—For instance a young thorough-bred horse is frequently put into training when two years old. Perhaps he may be of a weak constitution, and the bones at this period in a growing state, and not sufficiently consolidated and therefore not adapted to the wear and tear to which they are subjected. The consequence is, inflammation is set up, which leads to all those results.

In treating sore shins the great object is to give the animal rest, apply poultices, and administer a dose of laxative medicine. After some time cold applications are useful, and a blister may be applied; but before blisters are had recourse to all inflammation must be subdued.

### A Substance to supply the partial loss of Hoof.

(Translated from the French for the Veterinarian.)

Accidental breaches and loss of hoof in the horse being not only unsightly, but also causes which render shoeing unsafe, and prevent the horse from doing his usual work. M. Defays has endeavored to discover a substance that will not only conceal these defects, but be of such solidity as to bear the nailing on of the shoe, and of such consistency that it can be moulded into shape, so as to be easily applied to the parts, while at the same time it will not be affected by exposure to moisture. Of all the substances the author experimented with, gutta percha was the only one which offered any chance of success. When the fabrication of gutta percha soles were introduced, the author conceived the idea that means similar to those employed to fix them to boots and shoes would be equally efficacious for the purpose of attaching the material to the horses' hoof, but the experiment proved a failure, although he was assisted by M. Ledow a celebrated manufacturer of boots and shoes.

Notwithstanding all the care and trouble they took they could not obtain the slightest adherence between the substance and the hoof. After several failures it was found that an admixture of gutta percha and gum ammoniac offered some chance of success. Two parts of gutta percha with one part of gum ammoniac, melted together over a slow fire, and well incorporated by frequent stirring was found an excellent agent for the required purpose.

To apply it the hoof should be perfectly dry and free from grease. The composition after being warmed is to be applied with a spatula, and smoothed by a heated piece of iron. M. Defays adduces several instances in which this substance has been applied to horses, which have been able to work when they otherwise could not have done.

### Pleuro-Pneumonia.

We find the following address of the Massachusetts State Cattle Commissioners on the subject in a late number of the *Boston Cultivator*.

To the Farmers of Massachusetts.—The disease termed pleuro-pneumonia has appeared in several herds of cattle in the eastern portion of the State during the present season. The State Cattle Commissioners have adopted the most effective measures to prevent its dissemination. All cattle that have been exposed, with the exception of four, have been destroyed. The Commissioners have been forced to this mode of action by the logic of facts. These have been scrutinized with the utmost care and vigilance. No opportunities have been suffered to pass without improvement, and no efforts have been regarded as vain which promised to throw light upon the origin and characteristics of the disease. Two of the three Commissioners commenced their labours with a feeling that by careful inquiry and by thorough examination, they should be enabled to demonstrate to the public the expediency of the action of the former Board of Commissioners, as well as the groundlessness of the apprehensions of many in regard to the fatal character of the disease.

A number of persons had published treatises to prove that pleuro-pneumonia was generated in poorly-ventilated barns, and was not infectious. The facts as developed to the Commissioners, have constrained them to discard their first impressions, and to deny the positions of the various writers before alluded to. They have, moreover, thoroughly convinced themselves that the worst apprehensions in regard to the disease are well founded and wise. They have found the disease prevailing in barns of every variety of structure, and of all degrees of ventilation, and even in the open fields. They have traced it from root to branches, whither it flows as surely as the sap flows in trees. They do not find a single case outside of the line of trans-

mission. As surely as every rivulet tends towards the sea, does each case connect itself with its fountain head. The conclusion is irresistible, that if any disease be infectious this one is. In Massachusetts the disease was introduced by four Dutch cattle imported by Mr. Cheney, of Belmont.

But it is said the same disease exists in New York, New Jersey and Pennsylvania. The Commissioners determined to see for themselves. They went to New Jersey. They were met in Bordentown by a veterinary surgeon of that place, Dr. Jennings, by a large stock-breeder and noble-hearted farmer, Adolph Mailiard, and by others, members of a Committee of the Agricultural Societies. They visited herds which had been infected with disease; found some where a large portion had died. They killed and examined a sick cow, and identified the disease with that in Massachusetts. In all instances where it existed, it had been introduced by cattle brought from Philadelphia. The apprehensions of the farmers in that region had been aroused, and the Commissioners found that a species of isolation had been resorted to; but this was far from being thorough and efficient. Cattle were allowed on the highway, even in some of the infected districts. Very erroneous impressions existed in regard to the character of the disease, even among those who were called to treat it. Attention was given only to such animals as had come down with disease, and attempts were made to treat these by various remedial processes, and those which lived and recovered their vital energies were regarded as safe—an error, than which none more fatal exists. It has been demonstrated to the Commissioners for Massachusetts, that the last state of this disease is more pernicious than the first,—in other words, that recovery is worse than death. We say to the farmers of Massachusetts, when the disease appears in your herds, separate the sick from the well, and both from all other cattle; fatten the cattle, if you can, for beef, and kill all of them. This is the only safe and effective remedy.

The Commissioners followed the trail of the Bordentown disease to Philadelphia. There the disease had committed great ravages; one man was reported as having lost his entire herd of sixty cattle. Treatment was here resorted to as in Bordentown, but the disease had evidently become an *institution*, and was looked upon with apathy by all classes. They neither looked for its origin nor contemplated its future. Hence, as in England, many regarded the disease very much as they do those diseases which affect various kinds of fruit trees; as an evil to be endured, which will have its course and then disappear. In the mean time they must drink the milk and eat the meat of animals whose inflamed or putrid lungs cannot supply the due and healthy proportion of oxygen to the blood. From Philadelphia the Commissioners proceeded to Brooklyn, N. York., to visit the herds

said to be infected with a milk-disease similar in its character to the pleuro-pneumonia of Massachusetts. They went directly to Skillman Street, to the place described by Frank Leslie in his illustrated paper. Near the cattle-sheds were several cows apparently dying from disease whose symptoms did not differ from those of cattle infected with pleuro-pneumonia. Leslie's description had impressed us with the idea that the cows in these places had been fed with offal collected from the city, and that in consequence, and by reason of bad ventilation, the disease had been there generated. This opinion seems to have been endorsed by the surgeons who had visited those places. They had entirely misrepresented the state of the case. By the kindness and favor of Messrs. Wilson and Fletcher, distillers, we were permitted to examine the cattle of various milk-dairies. Mr. Fletcher, who, by the way, is a Massachusetts man and every inch a gentleman, conducted us through the cattle sheds and explained to us the mode of feeding. The "swill," about which so much is said, proves to be nothing more or less than the distillery grains, so highly prized in this region for feeding cattle. In addition to these, more hay of the very best quality is fed out than is generally fed by the farmers of Massachusetts.

It was evident to us that no disease was there generated. Mr. Fletcher kindly procured for us a sick cow, which was killed and examined, and proved to be affected with the genuine, infectious pleuro-pneumonia. One man had lost his whole herd of forty by the disease. Whence did it come? The information was voluntarily proffered. It was brought over by a cow in a ship from England about the year 1850. This cow was taken on board to supply milk, and after the arrival of the ship, was sold to a dairyman near the South Ferry in Brooklyn. This cow had the veritable pleuro pneumonia, which she disseminated and which previously had never been known there. The disease spread with great rapidity, annually taking off more than fifteen per cent. of the cattle. The practice of inoculation was resorted to but without beneficial results. The value of the milk business in that section is nearly destroyed. The cattle that do not die are fattened and killed for beef, which confines the disease, happily, to that region.

Farmers of Massachusetts! be not beguiled into a false security. By efficient regulations and prompt action, this fatal disease may be excluded from the limits of our State. But in this matter, the price of exemption is eternal vigilance. Be on your guard; keep all unknown and suspected cattle far from your herds. See that no stray cows are allowed to wander in your streets, and even take care to know the state of each herd whence come cows to be served by your bulls. Especially be cautious as to the cattle sent to a distance in the country to be pastured, and do not allow them to be re-

turned to your farm in the fall without a clean bill of health. Be not afraid of being thought "fussy," and in particular, place no reliance upon the theories of inexperienced or prejudiced parties who may try and persuade you that this disease is not infectious, or that animals which have once had it and have recovered, are safe companions for other cattle. Total abstinence from all that can contaminate is the only safety. This is our faith, the result of our study and experience.

Signed, James Ritchie, D. F. Thayer, Henry L. Sabine,—Cattle Commissioners.

Boston, June 3, 1862.

### Runaway Horses---A New Check.

A great many patents have been taken out of late years for stopping runaway horses, and in almost every saddler's shop we see engravings of apparatus devised to squeeze a horse's throat, or nose, or to catch up one leg and throw him down. But to all machinery it is objected that if a horse is really running away at a great pace he cannot be stopped suddenly by violent means without considerable risk to man and beast. A very ingenious invention, operating upon the horse's movements by moral force alone, has been recently brought out by M. Leveque, a French officer of the Cavalry School of Saumur. His plan will assuredly not be approved of by those who object altogether to the use of blinkers, for it is but an extension of the blinker system. The partizans of blinkers, however, for horses in harness, are, up to the present time, in an enormous majority. The leading feature of M. Leveque's invention is to induce the horse by his own natural instincts, and without any mechanical force, to hold his head in such a position that the bit shall act properly upon his mouth. Inside of each blinker he places a sort of leather fan, called *lunette d'arret*, which opens or shuts at pleasure by means of a safety rein. When developed, it only partially blinds the horse, and it is in the natural action of the horse to avail himself of the sight left him that the virtue of the system consists. If he throws up his head to run away, and the lunette is opened, he can see nothing but the sky, and he then inevitably brings his head down to the proper position in order that he may see straight before him. If, on the contrary, the habit of the horse be to escape the action of the bit by curving his neck till the chin almost touches his breast, the apparatus may be so adjusted as to prevent him from seeing anything but the ground, and he naturally raises his head. Thus the lunette acts both as a bearing-reign and a martingale, but more certainly, and without the dangers and inconvenience of those contrivances. For horses addicted to shying, the apparatus is particularly useful. As soon as the horse pricks his ears to shy at any object lying in the road, the driver has

only to raise the lunette, and the animal, seeing only the distant horizon, and nothing immediately about him, will go by or even right through the thing which frightened him without taking the least notice. At an exhibition on the Champs de Mars in Paris, horses went unhesitatingly through the flames and smoke of lighted lumps of straw, which a moment before, when the lunettes were folded, they could not be made to approach.

The apparatus is intended chiefly for horses in harness, but there is a form of it adopted for saddle-horses. Of course a hard-mouthed horse can not unfailingly be prevented from running away merely by the use of this lunette, but a great deal is done towards diminishing the danger when his head is got into a proper position, because he will then surely be pulled up before long, and in the meanwhile the driver can guide him.—*Ann. of Scientific Discovery.*

### Cure for a Jibing Horse.

J. R. S., writing to *Wilkes' Spirit* from Pittsburgh, Pa., thus describes an occurrence to which he was witness :

I noticed a novel cure for a fit of "balks" applied to a horse yesterday. A fine iron gray horse, about 16 or 17 hands high, and weighing probably 1,200 or 1,300 pounds, with a fine, large, open forehead and bright, clear eyes, showing no signs of vice or stubbornness, was coming up street harnessed to a light, open, express wagon, and at a corner suddenly balked, and could not be persuaded to move: his driver then tried the usual remedy of careless, brutal drivers, viz., a tremendous flogging with a barrel stave. The poor animal evidently could not understand the operation, and showed no sign of vice, but stood still, with his head turned back, and his ears put forward, starting at each blow, but not rearing or kicking. The brute who was driving him kept up his cruelty for at least ten minutes, until a bystander stepped forward and offered to start him, and the drive rather surlily consented. The gentleman went up to the horse and quieted him by patting and soothing, and then stooped down, and gathering a handful of dust from the roadway, thrust it into the horse's mouth, and then taking him by the head, the animal, whom coaxing, pounding, and flogging failed to move, stepped off as quietly and docile as a lamb. The cure was entirely new to me, and I thought it quite a valuable one. The almost universal mode would have been to flog, and hammer, until either the two-legged or four-legged brute got tired.

### Artificial Hoofs for Horses.

It is impossible to calculate the various useful purposes to which gutta-percha may be applied. One of the most ingenious applications re-

cently made of this valuable substance, is that of making artificial hoofs for horses' feet. Many ingenious devices have been resorted to, to attain this result, but the adoption of gutta-percha will, doubtless, supersede all others, as soon as its efficacy becomes recognized. What is required by the veterinary surgeon, is a substance possessing the consistence of horn, to retain the nails of the shoe; that will readily soften by heat, so as to mould itself to the required form; that it will be indissoluble in water, seeing that the horse's hoof is generally in contact with moisture; and, lastly that it be capable of uniting perfectly with the hoof. No known substance possesses all these qualities except gutta-percha. For the purpose under consideration it is prepared by being cut into fragments the size of a nut and softened in hot water; the pieces are then mixed with half their weight of powdered sal-ammoniac, and melted together in a tinned saucepan over a gentle fire, keeping the mass well stirred; the mixture should assume a chocolate color. When required for use it should be melted in a glue pot; the surface of the hoof must be scraped clean, and the gutta-percha applied as required. The application may be facilitated by the use of a glazier's knife warmed, by which also the surface of the artificial hoof may be smoothed and polished. In this manner many a valuable horse may be rendered useful, which, otherwise, would only remain fit for slaughter. On the score of humanity, also, this application of gutta-percha is to be welcomed.—*Ann. of Scientific Discovery.*

### Miscellaneous.

#### About Keeping Goats.

Many persons who cannot conveniently keep a cow would find it profitable to keep one or two common goats. They require but little care, may be supported at small cost, and yield a good supply of milk of superior quality. A goat, well kept, will yield from three pints to two quarts of milk daily, for a large part of the year, the quantity diminishing in the cold weather as the time for kidding approaches. It is much cheaper to keep a goat in town than to pay a milkman, and families everywhere will find the milk very nutritive and wholesome, and especially good for children in most cases. An English writer estimates that two goats are equal to a small Shetland cow.

Goats may be very cheaply supported. If picketted in a pasture in warm weather, or allowed to be at large, they will pick up their own living, eating readily almost every sort of green thing. Grass, weeds, twigs of bushes, vegetables, fruits, nearly everything that grows, will suit their taste. They are fond of dry leaves, corn-stalks, horse-chestnuts, and even eat poisonous plants with impunity. If con-

fined in a yard, or in closer quarters, they will take the scraps and waste of the kitchen—Some persons allow them to feed out of the swill-pail, but this practice cannot be commended. Cobbett says, in his "Cottage Economy:"

"When I was in the army in New Brunswick, where, be it observed, the snow lies on the ground seven months in the year, there were many goats that belonged to the regiment, and that went about with it on shipboard and everywhere else. Some of them had gone through nearly the whole of the American war. We never fed them. In summer they picked about wherever they could find grass; and in winter, they lived on cabbage-leaves, potato-peelings, and other things flung out of the soldiers' rooms and huts. One of these goats belonged to me, and on an average throughout the year, she gave me more than three half-pints of milk a day. I used to have the kid killed when a few days old; and, for some time, the goat would give nearly, or quite, two quarts of milk a day. She was seldom dry more than three weeks in the year.

The same writer adds, that "goats will pick peelings out of the kennel and eat them. They will eat mouldy bread or biscuit; fusty hay and rotten straw; furze-bushes, heath-thistles and, indeed, what will they not eat, when they will make a hearty meal on paper, brown or white, printed on or not printed on, and give milk all the while? I may add to Cobbett's list of odd delicacies by stating that my own goats have gnawed smooth the rough sides of my pile of hemlock bark, and have cleaned out all the powder-post from the sills of the woodshed!

But goats like most other animals, prefer clean food, and will not devour all the above-mentioned things if a supply of more desirable edibles are at hand. In the winter, it is well to lay in a few hundred pounds of hay—second crop is preferable—a few carrots and some fine feed. Indian meal is sometimes given to them, but it is too drying. They need water occasionally, but do not drink much.

The goat is one of the most hardy of our domestic animals, enduring easily all extremes of heat and cold. It needs the shelter of a shed or barn in wintry and stormy weather, and will lie anywhere on the floor, preferring a board to a bed. Its natural activity and nimbleness, together with a capricious disposition, fit this creature to enjoy a state of freedom. When roaming wild, on its native mountains, it loves to climb the most dangerous and inaccessible places, clinging on the verge of precipices by its wide-spreading and sharp-edged hoofs, and defying the pursuit of the hunter. This inclination it manifests in domestic life, by scaling sheds, walls, wood-piles, &c., with great agility. But the goat will bear confinement extremely well, continuing in good health and yielding the usual quantity of milk. On shipboard it is healthier than any other domestic animal, and is highly

valued on account of its sportiveness, its familiarity, and its ability to give milk upon such waste food as is there obtainable.

The milk of the female goat is sweet, rich and nourishing. It has the body and smoothness of cream, is viscid and strengthening, little productive of oil, but abundant in the matter of cheese. In tea and coffee it is far superior to cows' milk, and will go at least as far again in imparting color and flavor. In all kinds of cooking it is equally excellent. It has no peculiar or unpleasant taste and is not affected by what the creature eats. Onion tops have been given to the females, by way of experiment, without imparting an oniony taste to the milk. I consider two pints of goat's milk to be as good to a family, in every way, as three pints of cows' milk.

For most feeble and sickly children, as well as those in health, it is invaluable. It does not tend to form curds in the stomach, as cows' milk does, and is therefore frequently prescribed by physicians in cases of extreme weakness. It is sold for this purpose in Salem at twenty-five cents a quart. Invalids abroad often resort to the mountainous districts of Ireland and Scotland to derive benefit from the use of this article, which is there known as "goats' whey." Mr. Colman noticed that the Irish mountaineers, about the Lake of Killarney, kept from one to thirty goats apiece, for the sake of the tourists to that delightful region. In Spain and Portugal, goats are abundant, and in Lisbon, their milk is more commonly used than that of cows. The goats in those countries are driven into the cities in the morning, and milked at the doors of the houses. The district in France most celebrated for goats is the Canton Mont d'Or, where, in a space not exceeding two leagues (six miles) in diameter, upwards of eleven thousand are kept, chiefly to supply the city of Lyons with cheese. There are several other interesting particulars relating to the goat, which I will give in another paper.

G. L. STREETER.

—*New England Farmer.*

Salem, Jan., 1862.

HINTS TO FOWL KEEPERS.—B. S. H. gives in the *Prairie Farmer* his method of keeping fowls, thus: "The way I keep my hens laying and healthy, is in the first place, by giving them plenty of corn and oats, also some buckwheat. Last fall I commenced throwing out ashes from my stoves in a pile near my yard, so as to use with compost in the spring. I soon discovered my hens came to the pile every morning as soon as light, (cold or heat,) through the winter. They would pick up and eat coal, from the size of a wheat kernel to a thimble. My hens commenced laying in November, and have laid ever since. They are last harvest's chickens. If they cannot have access to wood charcoal, pick up and burn all the bones you can find and pound them fine, and place them where they can have easy access to them."

## Editorial Notices, &c.

LETTERS FROM CANADA, with illustrations. Tenth edition, printed at the "Morning Chronicle" Office, Quebec.

We are indebted to the author for a copy of this interesting and useful little work. It is of a kind to convey a great deal of useful information to persons in the better classes in the British Islands, thinking of emigrating somewhere; and we should be glad to see it distributed extensively with that object.

MANUAL OF AGRICULTURE, for the School, the Farm and the Fire-side, by George B. Emerson, and Charles L. Flint. Boston: Swan, Brewer, & Tileston, 1862.

We have received from the publisher a copy of a new edition of this work. Having noticed it on a former occasion, (December 1861), we will merely repeat that we consider it admirably adapted for the use of Schools, and a valuable hand-book to all interested in rural affairs.

REPORT OF THE MASSACHUSETTS BOARD OF AGRICULTURE.

We are in possession of the Ninth Annual Report of the Secretary of the Massachusetts Board of Agriculture, together with Reports of Committees appointed to visit the County Societies, with Appendix, &c., for 1861. This is a handsomely got up volume, and the Secretary of the Board, Mr. C. L. Flint, who is known as the author of several able treatises on agricultural subjects, has embodied in it much useful and interesting matter, amongst which we may mention a Report on Cattle Breeding and Feeding, a Report on the Wastes of the Farm, a Report of Committee on Wheat Culture, a Report on the Native Animals of the State, &c., &c.

## WANTED!

A THOROUGH BRED DURHAM BULL not over two years old. He must be from stock of good milking qualities. Apply, stating pedigree, price, &c., to the Editor of the *Agriculturist*, Toronto.

Toronto, June 20, 1862.

3t.

## A Thorough Bred 2 Year Old AYRSHIRE BULL

FOR SALE, by Mr. Denison, Dover Court  
Toronto.

April, 1862.

## THOROUGH BRED STOCK FOR SALE.

THE SUBSCRIBER has for Sale Durham and Galloway Cattle, male and female. Leicester, Cotswold, Lincolnshire, Down and Cheviot Sheep; Cumberland and Yorkshire improved Pigs. All imported stock.

GEORGE MILLER.

Markham, June 3rd, 1862.

6t.

## FOR SALE.

A LOT of thorough bred improved Berkshire Pigs of various ages.

R. L. DENISON,

Dover Court.

Toronto, Aug., 1861.

## Notice of Partnership.

THE Undersigned have entered into Partnership as Seedsmen and dealers in all kinds of Agricultural and Horticultural Implements, under the firm of James Fleming & Co.

JAMES FLEMING.

GEORGE W. BUCKLAND.

No. 14.

The New Wheat Insect.

We find the subjoined letter in a late number of the *London Free Press*, under date of July 12th. We have received several communications on the same subject, accompanied with specimens of the insect, from various parts of the country where it has been seen. In some districts where the wheat *midge* has not yet made its appearance, the farmers have supposed that the new insect is that dreaded visitant. Thus however, it is almost unnecessary to say, is not the case. The new insect is an *Aphis*, nearly resembling in appearance those often found upon garden or green house trees and plants. We are inclined to think from specimens sent us, that there may be more than one variety or specie of them, as they differ considerably in size and colour. They are all however very nearly allied, if not of the same species. Some of the specimens on opening the letter in which they were received have appeared of a bright scarlet or orange color, and very minute in size, a few of them with wings, the majority apparently without, and most of them alive. On opening the same letter the following day, all the insects are found to be changed to a brown or green colour, many of them dead, a few still living. Other specimens received have been considerably larger in size, varying from brown to a light green in colour, and apparently of a different form to the smaller kind. Some of the orange-coloured aphides with wings certainly resemble the per-

fect fly of the wheat midge a little in appearance at first sight, and this may have given rise to the impression that they were the same. The insects are, however, quite distinct. The *aphis* has appeared this year over very extended areas of the country. From what accounts have yet been given of it, it does not seem to cause any very great amount of injury to the wheat, although it must undoubtedly affect it to some extent:—

(To the Editor of the Free Press.)

DEAR SIR,—I had placed in my hands, by a gentleman in the market, an ear of wheat covered with insects very much resembling, at the first glance, the common "*Aphis*," found on the soft stems of roses and other garden flowers. My friend told me that the ear of wheat given to me was one out of a field taken without any special selection, every ear appearing to contain a great abundance of similar insects; the one I had contained about 100 insects, and many must have been shaken off in previous handling of the ear. Some of the insects possessed wings rather imperfectly developed, others had no wings, probably the not fully developed animal. On placing the insects under the microscope, they appeared to me to belong to the order "*Hemiptera*," or half-winged insects. The common tree bug is a fair example of the order. The insects had a largely developed "*rostrum*," which is the underlip of the insect, jointed, hollow, prolonged, and tapering to a point—in short, like the upper lip of the elephant called its trunk, but more horny and piercing at its point. Those insects which had not been disturbed were situated at the junction of the grain, with the ear stalk, and had their rostrums securely entered into the grain, which, in the specimen I had, was just formed, that is, the grain

was in its early membranous state with its white centre discernable. The result of the operation of such innumerable enemies as these insects must be the utter exhaustion of the grain. As the white kernel of the grain is secreted, it must be sucked into the hungry stomachs of these destructive animals; and the whole crop, supposing them to be as numerous throughout as on this specimen, must be shrivelled, half-grown, with very little flower in the grain, even if it ever reaches maturity. A more perfect boring apparatus, at the same time hollow, with great powers of suction, capable of drawing into the stomach of the animal every fluid particle in the grain, could not be devised or imagined. So soon as the grain hardens, the crop must be safe from this insect, unless future observation shows that it can derive subsistence from the fluids of the stalks as well as from the grain itself. Not one of the insects I have seen on this ear had attempted to penetrate the stalk, but that may be because being, as the saying is, "sworn at Highgate," it likes the juicy grain better, and when the grain becomes hard, they may turn their attention to the stalk. I do not think this very probable. But if I were a farmer and found my field covered with them I should be very much inclined to cut it down for hay, and wheat makes good hay when cut green, (I have cut many acres of it for hay when in Australia,) and sow the field for another crop of hay with any grain, such as rye or millet, or anything likely to yield a crop of this season. It would be found almost impossible to shake the insect off the ear. I doubt if a storm of wind and rain would do much to wash or shake them off, for they are possessed of good holding legs and feet and grasp the plant very tenaciously, and in addition to their legs, they have their "rostrum" to hold on with. Rain would only wash off the unattached; whether it would kill them I do not know, I should think not, unless the temperature fell very considerably. What other means the farmers possess for destroying the insects must be left to their own judgment. I doubt whether a grain of wheat once penetrated by the "rostrum" of these creatures can ever develop into good wheat, and whether grain so damaged as the ear shown to me would ever be worth so much as an average hay crop. But this is a matter for the judgment of each farmer. I shall be happy to show any farmer the insect and the penetrated grain, if he will bring specimens with him, for when once killed, the insect will not long exhibit its peculiarities. It soon loses its plumpness, and the shape of the rostrum is lost. Those I now possess will not be worth looking at on Monday, when your impression appears.

I think the prevalence of this insect is due to the continuance of dry weather, and may not be expected in ordinary seasons. If this country possessed the small birds of Europe, they would flutter about the ears of a wheat field, and pick

all these insects off before they would become so destructive. It is much to be regretted that small birds are so scarce. Every insect-eating bird should be amply protected by every farmer.

I remain, &c., HENRY LANDOR.

[The following is one of several letters addressed to the Editors of this Journal on the same subject.]

*To the Editor of the Canadian Agriculturist.*

DEAR SIR:—Enclosed you will find three specimens of wheat of the same variety infected with a kind of insect previously unknown in this section of the country.

As the wheat midge has of late years been committing serious havoc, in various parts of the Province, some farmers are of opinion that the insect above mentioned is the wheat-midge; but after a careful examination of this insect, and comparing it with Professor Hind's description of the midge, I am satisfied it is not the same. When first seen upon the wheat the insect was of a red fleshy colour; after a while it changed to a light green colour, probably caused by the animal's praying upon the ascending sap. The insect is very common throughout the County of Waterloo. If you could afford me any information in regard to the nature and habits of the insect,—if injurious to the wheat crop,—or if previously known in other parts of the country,—you would much oblige me as well as a large number of inquiring farmers.

Yours truly,

A. BARRIE.

Galt, July 14, 1862.

**The International Exhibition.**

LONDON, ENGLAND, June 11, 1862.

*Editors of the Canadian Agriculturist.*

Since my last there has been rain almost every day. There is a great deal of hay cut, and, although the weather is so precarious, the people manage to get it cured by close attention. I speak of course of the small fields in the immediate vicinity of the city, which I have had the opportunity of occasionally seeing. The races of last week seemed to be very much enjoyed by the population of the city of London. Situated as we are on the Clapham Road, we had a full view of the crowd, in astonishing numbers and in all sorts of vehicles, going and returning.

On Monday last, being Whit-Monday and a general holiday, the number at the Exhibition increased up to 60,000, or thereabouts. Yesterday the crowd was very great, and to-day they fill every vacant space. Looking down from the galleries, the movements of

the crowds of people give them a curious appearance, which suggests to one's mind the comparison to hardly anything so much as to that of a busy swarm of bees.

We (the jurors) have, we hope, got nearly to the end of our labours. For six weeks we have been nearly the whole time engaged in the examination of the products of the various countries of the earth from which articles of human food come; and there are few in which the Almighty has not made ample provision for his creatures. We find that the advantages of any one country over another are not so great as people are apt to imagine.

But of all the countries that have made an exhibition of their products none equal the colony of Victoria. Her wheat, her wool, and her gold proclaim her to be the richest country in the world, and the people have been active in their exertions to make a good appearance at the great exhibition. They have been late in getting all their things in their places, but they have eventually succeeded in making a very creditable display, both of the useful and ornamental. The samples of wheat, barley, and oats prove that the country is foremost of all in the growth of the cereals, while their paintings and photographs show that the fine arts are not neglected.

Samples of wheat weighing 66, 67, and one of 68½ lbs. per bushel are shown, and these of the most beautiful white varieties I have ever seen. Our grains are much admired, but I am compelled to admit that we are beaten by Victoria in the exhibition. We shall get a fair share of medals. There is no competitive examination, but the products of each separate country are compared with one another by themselves, and circumstances of climate and soil taken into consideration.

June 19th.

I had hoped by this time to have been able to give you some detailed account of the many interesting articles in the Exhibition; but the business of the jury has kept me so constantly engaged that I have been only able to take an occasional stroll from one court to another. We are now, however, almost at the close of our labours, and hope to finish to-day. It has been a much more tedious business than I at first expected, but I find that here as well as elsewhere the few that will work must expect to have the most to do. The numerous articles to be examined weary the examiner, and often exhaust his patience. The importance of our class makes it necessary to be particular. I think I have stated that there is but one class of medals. Our awards, therefore, expressive of the different degrees of merit, are either "Medal," "Highly Commended," or simply "Commended."

I shall not now have much time to devote

to a critical examination of the other departments of the Exhibition, as to-morrow I hope to do what I have been for some time desirous of doing, viz., go with my friend Mr. Prout to his farm, about thirty miles distant, to see his steam plough at work. He has an engine that works his ploughs and scarifiers, and he seems to be well satisfied with the results. This is his first year of putting the steam machinery into operation. He is carrying on farming on a large scale, at least we in Canada would think it so. He has forty acres in Swede turnips and mangel wurzel.

The month of June has so far been exceedingly wet. It has rained less or more every day, several days all day, and frequently heavily. We Canadians find it cold and uncomfortable, still the fruits of the earth are coming to maturity; strawberries are abundant; peas and young potatoes also are in the market in plenty. It is amusing to see the immense loads of rhubarb, asparagus, early cabbage, lettuce, and spinach, piled on the great heavy wagons, like loads of hay, and drawn by generally three and sometimes four heavy horses. I see them in the evenings, or early in the mornings, wending their way to the principal markets, where they are soon disposed of to the crowds of customers who have to be supplied.

Next week the meeting of the Royal Agricultural Society takes place. One of our jurors, Lord Portman, is the President, and has succeeded in having all the Jurors made honorary members of the society, so we shall have all the advantages of that position. The meeting is looked forward to with a great deal of interest. It takes place in Battersea Park, between where I am living and the Exhibition. I shall give it all the attention I can. The trial of implements, which will be very numerous, takes place some twenty miles off, and will be a very interesting part of the exhibition. I will endeavour to give the whole affair as much attention as I can, and communicate what I think will interest my Canadian friends. It is to be hoped the weather will be fine, but this morning is still lowering and threatening rain, but it will surely be fair soon. This continued rain surprises me the more because when I was here in 1851 the weather during the month of June was very fine indeed, very like Canadian weather.

I learn that much of the grass that has been cut is seriously injured, and will only be fit for litter.

June, 26th.

Since my last date I have been down in Hereford at Mr. Prout's farm, and seen his plough at work. His farm, of upwards of 400 acres, is admirably adapted for its operation, and it was doing the work in the most effective manner. The farm is a stiff clay,

and the steam machine worked it up to a depth of seven inches, and moved at the rate of about four miles per hour, or twice as fast as an ordinary horse team. The whole is so admirably arranged and all the parts so complete, that the time required to start from each end of the field is not longer than is required to turn a team of horses, and it takes four furrows at once. The estimate is, that it does the work in the stiff clay that would require thirty-two horses. The only drawback to its complete success is the occasional going wrong of some part of the apparatus, and the consequent stoppage of the work. This is the case sometimes, but not often. Upon the whole I am of the opinion that upon a farm of four hundred acres, which lies favourably, steam cultivation can be employed with advantage.

The Show of the Royal Agricultural Society, is now going on here. I was in the stock yard yesterday and was much pleased with the arrangements. There is a splendid show of animals. The Short Horns are of excellent quality. The Devons, Herefords, and another very long-horned breed from some of the counties, are all very fine. The Gallo-ways, and red Suffolk polled cattle are also very good. The latter breed are much like the Devons, only without the horns. I admire them much; they are noted for their milking qualities.

All the different breeds of sheep are here represented by specimens of the most approved form, and of the finest quality obtained by the art of breeding. There are some majestic-looking rams from the Highlands, of the blackfaced breed, with horns of imposing proportions, and with carcasses of dimensions far beyond anything I ever supposed they attained to. The Oxford, the Shropshire, and several other varieties of Downs are all excellent of their kinds, but for beauty and symmetry of form none beat the Leicesters and the old South-Downs. Swine are well represented by the Berkshires, large and small, the Sussex, Yorkshire, Suffolk and Dorsetshire breeds.

I have not mentioned the Welsh, Irish, and Jersey cattle. Numbers of all these are on exhibition, and also foreign cattle from France. There are Ayrshires that compare favorably with any from Scotland, and there are some good ones from there. Some of the Dutch cattle are excellent animals, and from Switzerland there are many of the native cattle that are by no means bad. But the Short-Horns still maintain their superiority, and are on this occasion well represented. There are animals amongst them that would repay one for going a long distance to see them.

Horses are exhibited of all classes, from the Shetland half starved poney, to the monstrous Clydesdale, the Suffolk and dray horse. There

are some of the most noted thorough-breds, hunters, roadsters, carriage horses, and useful ponies of fine shape and substance. The Suffolks are the most popular of the large breeds, and are really good animals. Some of the Clydesdale breed are very much superior to any I had ever previously seen. One mare of that breed and which took the first prize is a remarkably fine animal and is held at 600 guineas.

I have not yet been in the Implement Yard where the Implements are in motion, but I have been in that where they are on view not in motion, and will reserve the description until I have seen all in both yards.

We have now concluded our duties as jurors of the International Exhibition. Canada will receive a goodly share of medals and commendations. I perceive that the season has been very dry in Canada. It has been quite the reverse here, as I have already stated. There have been two or three fine days this week, and a good quantity of hay will no doubt be secured.

It seems to stand the rain better here than with us, I suppose because the sun is so constantly obscured. Your's, &c.,

E. W. THOMSON.

## The Season in Huron.

*Editor of the Canadian Agriculturist.*

SIR,—I see by the Newspapers that other parts of the province are blessed with fruitful showers which we very much need here. Since the latter part of April we have had but two or three light showers, which damped the ground to the depth of an inch or two, when it would be dry again in a day or two. No one here ever remembers to have seen such a dry time.

The Spring wheat, sown early, is about shooting out, and is hardly a foot high. There are no meadows fit to mow, many have turned their cattle into them; late oats is just peeping up among the clods. Not only has the weather been dryer than usual, but the Spring frosts have been more severe also. The Fall and Spring wheat sown on new land were never injured so badly by Spring frosts as they were this Spring. Other Springs we generally had a light frost after rain, but this Spring we had the frost without the rain. Nearly all the currants, cherries and plums were killed by the frosts.

A dry time injures comparatively new settlements like this, where the land cannot be or is not cultivated deep among the stumps, more than older parts of the country, where a better system of cultivation can be followed.

Yours respectfully,

A WAWANOSH SUBSCRIBER

Wawanosh, July 4, 1862.

Written for the *Canadian Agriculturist*.

## Hints for an Agricultural Report of the Township of Hamilton.

*Continued from page 395.*

Passing from stock to crops, in which a large proportion of our farmers are more directly interested, we would notice first, Fall Wheat. The method pursued with this crop when it was cultivated extensively, was either to summer-fallow the land, giving it generally three ploughings; or else to sow it after a pea crop, giving it one or two ploughings, as was found convenient, or the state of the ground required. In the early settlements of the township, fall wheat was the only kind grown, and when so much of the country was covered with wood there was little danger of winter-killing—the *fly* had not then been heard of; the *rust* was the enemy most dreaded by the farmer. We have frequently heard old settlers remarking how much easier they could get a good crop of wheat *then* than they could *now*—“every thing they put in the ground seemed to grow well; if they could only get the seed sown they were sure of a good crop, &c., &c. With the clearing away of our forests, the ground became more exposed, so that the snow, (the great natural protector of our wheat and of our fields in winter), disappeared more rapidly under the influence of the wind and the sun, and the wheat plants were weakened or destroyed by the spring frosts. Then the plants that were left tillered too much—became too rank in their growth, and the rust and mildew finished the crop. Notwithstanding all the increased skill and care of our farmers so much did this become the case that the cultivation of fall wheat has been given up in the front part of the township, and is now grown in the middle and rear parts in yearly decreasing quantities; the land in these parts being higher and dryer, and the soil lighter than the front.

The varieties grown here have been various. When we first came to the township the White Flint was a favourite kind; then the bald red chaff white wheat was common; then the Hutchison white became the favourite for some time, but we think the Soule's white wheat has become the most valuable variety, and, since its introduction, has almost driven all others out of cultivation. The blue stem has been grown to some extent, and has done pretty well. The Mediterranean and the Kentucky May wheat have been tried, but with no very marked success. The second prize for the 25 bushels, and the first prize for the two bushels have been taken in the township at the Provincial Exhibition.

The repeated failures of fall wheat no doubt at first induced our farmers to try spring wheat; like most new things it was tried but sparingly at first, but as its cultivation became better un-

derstood and better varieties were introduced, it became more popular. By the last census it appears that four acres of spring are now grown for one of fall wheat in this township.

Spring wheat is sown after all kinds of root crops and Indian corn—it is sown after peas. The land is generally ploughed twice in the fall, when the manure, if any is used, is put on, and then cultivated in the spring, or else simply harrowed in. In this way good crops of wheat are often obtained, and this method is extensively practised. Sometimes land is *rag* or *bastard* fallowed—that is, the land is ploughed and harrowed immediately after the hay crop is taken off, and then allowed to lie till after harvest, when it is cross-ploughed and harrowed; it is then ridged up before the frost sets in, and sown in the spring, without any further preparation, or else cultivated and sown—manure may be applied at any of the ploughings, as is convenient; when applied before the first or second ploughing it becomes well mixed with the soil. Sometimes a field that has been mown for one or two years is ploughed up with a Michigan Sod-and-Subsoil plough, and sown with wheat; but this method seldom produces such good crops as the other, but there is less labour by this way. Spring wheat is often sown after fall wheat; on land that had been summer-fallowed for the fall wheat the crop is often very fair; it is sometimes sown on the same ground two or three years in succession, but this is not often profitable, as it seldom yields well to sow wheat after wheat; sometimes land, when very dirty, is summer-fallowed for spring wheat; the crop in this case is apt to be too strong. The great breadth of land under root crops in late years, and the increased quantity of peas grown, render the use of other preparations for spring wheat almost unnecessary.

*Varieties*—The kind first grown here, as far as we know, was the Italian Spring Wheat—a heavily bearded variety, which though it hardly yielded so well to the acre as some varieties that came after, was, on the whole, a good hardy wheat, and made good flour. The variety next introduced was the Siberian—a fine bald or very slightly bearded variety, with a bold plump berry, so much so that it was sometimes mistaken for fall wheat. This kind gave a great impetus to the growth of spring wheat, for the first few years after it was introduced it yielded extremely well, and its fine sample made it much sought after,—but, after a few years, it became very subject to rust, which, in the season of 1848, caused a great failure of this kind, and led to the abandonment of this variety.

About the time the Siberian spring wheat was failing, two other kinds were introduced—one called the Bald and the other the Bearded Club. The Bald Club is an excellent variety, still much grown on our light soils, where it can be sown early, so as to escape rust and fly. It

always commanded the highest price of any of our spring wheats: it is, as named, a bald variety; and in favourable seasons, a very fine sample with large bright berries. The bearded variety grew a very short ear, resembling a *club* with six or eight rows in the ear; it was best adapted for low, strong land, as it was not subject to rust, it yielded middling well, but was very hard to thrash—no fear of its shaking—it was rather fine and weak in the stem, very apt to lodge, which made it troublesome to harvest—there has been none of it grown here for many years. The Black Sea wheat, and the Tea wheat, were tried to some extent, but with no marked success. These two varieties were very similar, if not identical; rather soft in the straw, very apt to lodge and crinkle down; there has been none of them grown lately. But by far the most valuable variety that has ever been tried here is the "Fife Wheat;" it began to be introduced into this township in 1849, having been grown in the neighbouring township of Otonabee for six years previously, and on all low wet strong land has entirely superseded all other kinds. Its most marked quality is its being always free from *rust*, and its bearing to be sown so late in the season as to escape the *fly* in a great measure; it is a bald variety, moderately productive, is reckoned rather hard to grind, but makes good flour. Its introduction was providential, as without a variety with its properties it is hard to say what the farmers on the low wet lands in the township would have done.

It does not reflect much credit on our farmers that they have not ere this bestowed some public testimonial on the gentleman who was the means of introducing it into the Province—he certainly has been a public benefactor, and we hope he will not be allowed to pass away without some mark of esteem for his public spirit; would all our farmers who have directly benefited by it (not to speak of other classes who have been indirectly benefited) contribute only one dollar each, we feel assured it would make a handsomer testimonial than was ever presented to any man in Canada.

There is a variety called the China wheat that has been tried of late; it is a heavily bearded kind, said to be best on light land; it has not been sufficiently tried to see whether it will prove valuable or not. The first prize for spring wheat has been twice awarded to this township at our Provincial Shows.

Before passing from the cultivation of wheat we would notice briefly the insect enemies by which it has been attacked in this township; in doing so we will confine ourselves chiefly to our own observation and experience. During the years 1840 to 1844 a fly that somewhat resembles the Hessian fly in the manner it damaged the wheat crop; it did considerable damage, but it soon passed away, and we have not observed it in any considerable numbers until

the past two seasons, when it has again made its appearance. We are inclined to think it is not the Hessian fly, but some one or other of the species of Joint flies. The larva of this fly we have found in the first or second (very rarely in the third) joint from the ground; when the larva makes its escape it eats through one side of the stem of the wheat, thus causing it to crinkle and fall down. The larva is of a dark brown colour, tapers to both ends, and is rather more than the eighth of an inch long; its ravages have never been very extensive, therefore the fly has been little noticed.

The next insect enemy to the wheat that made its appearance was a caterpillar, which we first observed in 1843, and in that and the two following years it was rather prevalent, and caused considerable alarm among farmers at the time; after 1845 it passed away, and was not observed till 1853, when it again made its appearance, and was to be found in most of our wheat fields till 1856; since then we have not seen a single specimen, nor heard anything of its ravages. This caterpillar is called, in the New York reports, "Gaylord's Wheat Caterpillar," and we believe the fly that deposits it has never been ascertained. Asa Fitch, the New York State Entomologist, to whom we sent specimens in 1856, states so, and was very anxious to have the parent fly ascertained. We have, on one or two occasions, attempted to preserve them through winter, but have always failed. There was mostly only one or two caterpillars in a head of wheat, (occasionally we have seen three,) they completely destroyed the grain of wheat they were bred in; and, when numerous, might be found crawling about the barn in great numbers, after the wheat had been taken in. When cleaning up the wheat after thrashing, the screenings would appear alive with them; and, when disturbed, would roll or coil themselves up. When the caterpillar was first seen, they were not more than one-tenth of an inch long, those we kept grew till they exceeded  $\frac{3}{4}$  of an inch in length. On their first appearance they had a soft cylindrical body of a tawny colour; the head much darker than the body, with the appearance of five dull stripes along the body and at least six pairs of legs; they destroyed the wheat soon after it was put in the barn—those we kept gnawed hard grains of wheat, beginning at the seed end; they seemed to prevail alike in early or late wheat, as we have found them in the fall wheat harvested in July, and in spring that was not sown till after the middle of May.

The damage done by this enemy of the wheat was trifling, compared to what was done by the wheat fly or Midge, (the *cecidomyia tritici*) which first made its appearance here in 1853, and has ever since injured our wheat crop less or more. This insect is too well known to all our farmers to need any description. It is now well known the fly comes first out from about

the middle of June to the 1st of July, according to the season, as it is late or early, and remains some weeks; it deposits its eggs in the ears of wheat as they emerge from the sheath—that is, just as it is shooting out—calm moist weather being favourable to them; they mostly deposit these eggs in the evening and during the night; dry windy weather in a great measure prevents their ravages. From a knowledge of their habits and the time of their appearance, we have been led to sow spring wheat late, so that the flies may have passed away before it heads out; for this purpose the Fife wheat answers admirably, as it is not subject to rust even when sown very late. The last season our wheat has been attacked by two other enemies—the Army Worm, and what may be called, an *army of aphides*. The army worm made its appearance here about the first of August, and remained about a fortnight, destroying the wheat and other crops; it was worse in spots of lodged and green wheat, and very partial, in some fields doing serious damage, and in others but a short distance off, doing little or no damage at all—in fact not one to be seen. They caused great alarm at the time, but did not do near the damage that was anticipated. The worm was from an inch to an inch and a half long, striped with bright yellow stripes along the body, with eight pairs of legs, and had altogether a formidable appearance; it could travel easily from one field to another, taking the grass clean off on its route. We secured some specimens in a glass, when they soon passed into the *pupae*; in this state they remained fifteen days, when they emerged into an ordinary looking moth of a tarnished yellow or drab colour, inclined to russet, with a small white dot near the centre of its fore wings, and a dusky oblique stripe at their tips; a full scientific description of it may be found in most of the agricultural journals of the past year from the pen of Asa Fitch, New York.

The other destroyer of our wheat alluded to had quite a different look; it appeared about the same time as the army worm, at least we did not observe it until examining our wheat for that worm; it was an aphid, or plant louse, and in some cases filled the ears of wheat and oats; it was small, of a dull red colour, with two long dark colored antennæ, which it had the power of laying along its back, giving it the appearance of a black line along each side, with these it usually kept feeling forward; close behind the antennæ were two dark spots or eyes; it had three pairs of legs, the hind pair much longer than the others; it had dark protuberances on the hind parts, and a short tail-like appearance behind; the body was smallest before, and gradually became larger till past the last pair of legs, when it tapered off rapidly; they were pretty active, and could run from one part of the ear of grain to another. Our magnifier was too small to enable us to say what its mouth

was, but we judged it was adapted for sucking, and not for cutting or tearing; they were always in clusters, and appear to multiply rapidly. On putting some in a glass they became, in a few days, a small clear-winged fly. We are inclined to think they did considerable damage to spring wheat.

The grasshopper has occasionally attacked our crops; the greatest damage done by them was in 1858, when they seriously injured late spring wheat, oats, root crops, clover seed, and pastures. In 1859 they were numerous, but the damage done was not so extensive, as they were that year destroyed in great numbers by a parasite. From their great importance we have dwelt thus particularly on the wheat crop and their enemies; we will now pass over our other crops more rapidly.

**Barley.**—This crop is not grown extensively in the township. It appears from the last census that only 300 acres were in this crop; its cultivation has fallen off, and spring wheat taken its place; on the heavy clay land the two-rowed variety is mostly sown, and the six-rowed on the lighter soils; it is mostly sown on wheat stubble; often one or two ploughings. The best crops are raised when sown after a root crop. It is a favourable crop to seed down with. It is sometimes attacked by the wheat-fly or one very similar. The first prize for Barley has come twice, and the second twice to this township, at the Provincial Show.

**Oats.**—This crop is only grown in sufficient quantities for home use, little or none for export. They are mostly sown on wheat or barley stubble, but sometimes on green-sod and clover lea; they are, on the whole, a pretty certain crop, not much subject to blight or the ravages of insects, though they were attacked by the grasshopper, (as stated above) some years ago, and to some extent by the Army Worm and aphid last year. The white varieties are mostly grown, though the black ones are to some extent; the Potato, Hopetown, Berlin, and other heavy kinds have been tried, and though they yield very superior samples, yet we believe they are found not more profitable than the common kinds. At the Provincial Shows, the first prize twice, and the second prize three times, have been awarded to this township.

**Peas.**—This is an important crop, not only for feeding purposes, and for export, but also as a preparatory crop for wheat. They are sown after all kinds of crops, but mostly on land that has been in hay or pasture the previous year. Generally the land for peas is ploughed in the spring; they are often the first crop sown. They are sometimes damaged by mildew, never much by insects, though some years they are a little *buggy*. Of this crop there are many varieties, the Whit's Creeper being most common. Some of the early varieties are sown by some farmers for the United States market. The large Marrowfat peas were grown largely at

one time, but they have not been so much sown lately. The Black-eyed Marrowfat is at present a favourite and productive variety. The first prize for Marrowfat Peas was taken once in the township at the Provincial Show.

**Rye.**—Of this crop very little is grown; what is is generally sown on some of our light soils. Its cultivation is rather fallen off in late years. We believe it is not subject to the attacks of insects.

Of *Buckwheat* still less is grown, and that generally in small patches for family use.

**Indian Corn** has not been much grown, as it is not a crop on which our farmers place much dependence; what is grown is mostly for family use, and for feeding purposes, for which it is very useful and convenient. We think it deserves more attention at the hands of our farmers than it receives, as it is a good preparatory crop for wheat or barley, and can be used as a fallow crop for cleaning the land with.

### Canadian Timber at the International Exhibition.

The following description of the woods of Canada in the International Exhibition, is from the *Gardener's Chronicle* of June 14th, and probably from the pen of its accomplished conductor, Professor Lindley. Our readers will perceive that a permanent mine of wealth is to be found in our forests, if properly managed, and that our commissioners to the great Exhibition have executed their duty in an efficient and praise-worthy manner. That with our cereals and other productions, natural and artificial, notwithstanding the very small and inadequate sum of money given to the enterprise by our colonial government, enough has been accomplished by economy and good management, to show the world that Canada is not that country of ice and snow, with which it has too long been associated in the popular mind:—

"The visitor to the International Exhibition who shall seek for timber will see on his right in the distance, as soon as he enters the Eastern Dome, a noble pile reaching nearly to the roof of the transept. When he approaches the pile, he will find that its base is surrounded by most admirable examples of what Canada can produce; for he is within our great North-East envy American Colony, the pride of England, the of the United States. There is not such another display from the New World; and when we consider how near is Canada to our own shores, the rapidity of intercommunication between us, and the enormous wealth which this "trophy" represents, it is difficult to avoid feelings of something like triumph at such a demon-

stration of British power. And yet there are those who would pull the trophy down, because, forsooth, it is thought to stand in the way of a painted window. We have not, however, sunk to such effeminacy as to prefer tinsel to iron, or to sacrifice the interests of millions to degenerate taste. For ourselves, we own that we admire the work of the Almighty, even in the rude form of timber, very much more than any combination of blue, red, and yellow glass in the cathedral window. And so does the intelligent part of the public.

To planters in this country the exhibition of timber in Canada, is particularly interesting, because not a tree is represented in it with which we are unfamiliar. We can grow them all on our own estates if we think it worth while; and, given time enough, we can grow them as well. More especially does it concern those who already possess old specimens of Canadian trees to study here the evidence of what they may come to. Take, for example, Black Walnut, which grows magnificently even near London. There is one specimen (No. 53) which is four feet seven inches in diameter, exclusive of its bark. Such timber can be had in Quebec for £71 per 1,000 feet cube. The specimen to which we now refer must be about 400 years old.

North American Elms thrive perfectly with us. They are, however, we believe, exclusively *Ulmus Americana* and *fulva* that have been introduced. We now see that another kind, called the Rock Elm, or *Ulmus racemosa*, is superior to them and to our own; the wood being finer in the grain and less brittle. Of this there is a specimen, about 2 feet 8 inches in diameter.

Weymouth Pines are among the commonest of our hardy conifers. They yield the "Pine-wood" of carpenters. Little, however, do our foresters know of the huge specimens that swarm in Canada. "Average height 140 to 160 feet; average diameter, 3 to 4 feet; but common near Lake Erie 5 to 6 feet in diameter and 200 feet high; or even in some cases 22 feet in circumference, 220 feet high, bare of branches for 120 feet to the first limb." Such monsters are, however, too big to exhibit, and Canada modestly limits herself to about 2 feet 10 in. or three feet in diameter.

Then there is *Pinus resinosa*, or the Red Pine, which dislikes our eastern climate, 3 feet 6 in. in diameter, which is about twice its usual size. But there is no encouragement to plant it here.

The Ash of Canada (*Fraxinus Americana*) famous for its toughness and strength, invaluable for the handles of axes and other implements, is displayed in its small forms as well as in the giant proportions that it assumes when full grown. One round, with 305 circles of annual growth, is 2 feet 10 in. in diameter, an admirable example of timber.

There is Oak, too, (*Quercus tinctoria*), red (*Q. rubra*), and white (*Q. alba*), the latter little inferior to British heart of Oak, and not far off 4 feet in diameter. This tree, as much at home with us as with Canadians, is said to be sometimes 21 feet round! in Western Canada.

Then we have Occidental Plane, or Button Wood, 4 feet through; Tulip tree or White Wood, 3½ feet, and Bass wood or American Lime, more than 2 feet, all excellent for cabinet and joiners' work, though unfit to bear exposure to weather.

Add to these numerous specimens of the fair growth of American Chestnut, Hickories, Maples, Beech, Birch, Hornbeam, Hemlock, Spruce, Tamarac, or American Larch, and he who would thoroughly understand the nature of Canadian timber has a field for serious study hitherto unexampled: how serious in a mercantile point of view, may be gathered from the fact, that Canada exports annually about 30,000,000 cubic feet of timber in the rough state, and about 400,000,000 feet, board measure, of sawn timber. The revenue derived by the Province, during 1860, for timber cut in the forests, amounted to about \$500,000." It appears that of the 60 or 70 varieties of woods in its forests, there are usually only five or six kinds which go to make up these exports so vast in quantity; the remaining fifty or sixty timber trees are left to perish or are burned as a nuisance, to get them out of the way. The Commissioners truly observe that by showing in the markets of the world, that it has these valuable woods, and can furnish them at unprecedentedly low prices, will secure additional purchasers, a result that the capital display in the Exhibition building is admirably adapted to secure. The Commissioners from the Colony state that in extent, and in the value and variety of its woods, the great forests of deciduous trees of North America surpass all others; the most remarkable of this great mixed forest being that grown in the valley of the St. Lawrence. The western coasts, in high latitudes, furnish only or chiefly the Coniferae. High summer temperature and abundant summer rains, are unquestionably, the conditions necessary to produce the deciduous forest trees. Western coasts, in high latitudes, have the necessary moisture, but not the high summer temperature; Western prairies, east of the Mississippi, and the vast deserts west of it, have summer heat but not moisture; hence the absence of all trees in one region, and of the deciduous trees in the other. In this country we have probably all the conditions, except time, under which the Canadian timber has been produced.

All the hardy trees belonging to the Canadian Exhibition are capitally shown, by the production of both "rounds" or transverse sections, and planks, so that the grain may be examined in each direction; and we only do justice to the Canadian Commissioners when we point out the

skill of their arrangements; not forgetting their excellent Catalogue, which has afforded us some part of the information now laid before our readers.

In the other North American colonies the timber exhibited is merely in the form of hard specimens if produced at all. That of Vancouver and British Columbia is still at sea, with the exception of a few examples from the form, among which will be found the unsurpassable Douglass Fir, to which we have lately drawn attention on several occasions, and the Cypress of the settlers, a beautiful white wood would be produced, we believe, by *Thuja gigantea* (*Libocedrus decurruns*.)

#### OPINION OF THE DUKE OF NEWCASTLE.

Subjoined is a circular letter addressed through Dr. Lindley, Colonial Superintendent, to the several Colonial Commissioners, by His Grace the Colonial Secretary, which will be read with interest.

"DOWNING STREET, 4th June, 1862.

"My dear Dr. Lindley, Now that the Colonial Department of the International Exhibition is very nearly completed, I must express to you, first, my thanks for the trouble you took in showing me the various productions, and, next, my extreme admiration of the spirited and successful manner in which the colonies, with scarcely an exception, have responded to the invitation of the Commissioners to send specimens of their natural produce and industry for the information, and, I may well add, the instruction of the nations of Europe.

"It is impossible that such a display of what the Colonial portions of the British empire can produce should be without a very material influence upon the future prospects and prosperity of each of them. In gold and other metals, in cereal produce, in timber, in wool, above all in cotton, the visitors of the International Exhibition will find the English colonies eclipsing all competitors; and I am much mistaken if foreigners will not find in the department allotted to them more to excite their admiration and wonder than in the more showy and artistic displays, which do so much credit to the taste, energy and manufacturing power of the mother country.

"I assure you that not only officially but individually I am delighted at the position before the world which the Colonies have assumed at the Exhibition.

"I am, my dear Dr. Lindley,

"Your's very sincerely,

"NEWCASTLE."

The seed of winter wheat retains its germinating powers from three to four years, of spring wheat two to three years. oats two years, beet-root six to seven, swedes five to six.

### Irrigation for Grass Lands.

We are again amid the fervid heats of July, the hottest and oftentimes the driest month of the year. One now only needs to look over the parched fields, especially in a dry season, to understand the need of irrigation. Even in seasons of average moisture we could use to advantage many times the quantity of water that falls from the clouds. It would always make the hay crop a certainty, and often quadruple the yield of grass in the irrigated fields. It was not strange that the Romans living under the bright skies of Italy, early found the advantage of damming their mountain streams, and turning them at pleasure upon the meadows below. It would seem from the account of Virgil, that whole districts were famous for the crops procured mainly by this method. Irrigation must have been an art well understood long before the Christian era. Is it not strange that in a climate quite as much subject to drouth as that of Italy, irrigation should be almost unknown among us? With a climate that demands it, and with unrivalled facilities for its practice, in most of the northern States, not one farmer in a thousand has availed himself of the treasures of water within his reach. Nothing could better show the neglect of agriculture among us as an art than this fact. Few people are more ingenious than ours, or more quick to take advantage of the facilities which Nature offers to save labour and to create wealth. We abound in all useful inventions and labour-saving machines.—We dam the streams to turn innumerable wheels for manufacturing purposes; to make fish-ponds and adorn our ornamental grounds; to make model lakes and raise our annual crop of ice, for the delight of Europe and the Indies. But how rarely is a stream turned from its course to fertilize the land and increase our harvests.

Few have any conception of the value of water as a fertilizer. Many turn the streams made by rains in the highways into the adjacent fields, but they attribute all the increased luxuriance of the grass to the matter deposited. No doubt street refuse, such as the rain washes into the meadow, is an excellent fertilizer, but the rain itself contributes to the result. Far beyond the line of deposit, you see the effects of the water.

Just how the water operates to fertilize the soil we may not be able to state. Of the fact there can be no doubt. We see the power of water to make crops in every drouth that comes. There are fields of light gravelly soil, whose crops of grass are nearly doubled in wet seasons. It is pretty safe to infer that water made the difference. Water is a powerful solvent, and helps the decomposition, not only of vegetable fibre in the soil, but of its mineral constituents. You can not wash a stone so clean that water will not act upon its surface, and after a few hours wash away something more from it. It is prob-

able that the water is all the while preparing plant food from the soil where it is present, and of course the more of it we pass through the soil, the more nourishment the roots of plants are enabled to take it up.

We have recently examined two small valleys, flowed for skating during the winter, and drawn off in early spring. In both you can detect the water line in winter by the greater luxuriance of the grass. Both streams that fed these ponds are dry, or nearly so, in summer, and never carry any very large volume of water. The basins that contain the water are small, and mostly covered with grass, so that they are turbid even in rains. There is little appearance of sediment when the water is drawn off in the spring, and it is nearly certain that the beneficial effect is mainly owing to the presence of water in the winter season. If the water helps the grass crop under these unfavourable circumstances, it must help it much more when it bears a rich deposit, and is applied at the growing season.

We have in this State two examples at least, of the successful application of irrigation to farms—that of A. B. Dickinson, of Steuben Co., and L. D. Clift, of Putnam Co.; accounts of which were published in the *Agricultural Transactions* for 1855. In both these cases, the method is simple and the expense not beyond the means of the most thriving farmers who have streams convenient for this purpose. In both, the results are all that could have been anticipated. The method is to dam the stream at a point above the lands to be watered, and to turn it on at pleasure, by means of a gate and channels of distribution. These main channels are furnished with side conduits which are merely furrows made with the plow, and having just descent enough to carry the water. When the water is turned on, these channels overflow, and the water is distributed over many acres.

Mr. Clift pursues his irrigation even in winter, and it is this feature probably that will be looked upon with more hesitation than any others. The water freezes sometimes as it flows, making a broad field of ice a foot or more in thickness, where it remains until dissolved by the suns of spring. It is probable that the ice affects the soil thus protected just as the ice-covered pond does. It is completely shielded from the alternate thawing and freezing; the frost does not strike in deeply, and comes out very early in the spring. It is his testimony that "the grass in all such places is first in spring, and grows with great rapidity." He also improves other seasons when the stream is charged with sediment, and spreads it over the land as a top dressing. Besides the sediment which is carried in the water, a good deal collects in the bottom of the pond, which is carted out when the water is drawn off, and makes excellent manure. This is spread upon portions of the field that receive the smallest supply of water. He cuts above a hundred tons of hay on forty acres of land,

which is certainly double the average for the mowing land of the state, and uses no other manure.

Mr. Dickinson makes great account of increasing the natural deposit of sediment by artificial means. He plows and harrows land that is to be overflowed, and stirs up the soil after it is under water to make it very muddy. Even the subsoil that is thus spread over grass land is found to be an excellent fertilizer. His grass crops are enormous, and the best possible commentary upon his method of irrigation.

Now we have thousands of farms all over the country quite as well, or even better situated for artificial watering than these. In many cases a few days' labour by the ordinary working force of the farm would make a pond and the necessary channels for watering a few acres. The work once begun would demonstrate its economy and lead to the watering of all the available portions of the farm. Lands that are now an incumbrance, hardly paying taxes, might be brought into a high state of productiveness. We call the attention of our readers to this very important topic at this season, when the scythe sweeps so many acres prolific in five-finger and briars, but poor in grass. Cheap and careless irrigation pays, and the more systematic and perfect it is, the better it pays, as a general rule. Use our streams rightly, and we shall find them richer than Pactolus, plowing over golden sands. —*Agriculturist*.

### Economy in the Preservation and Storing of Manure upon a Farm or Garden.

The following statement will, it is hoped, be found interesting to your readers. It is based entirely upon experience gained during the last 10 years, in which the following practice has been observed, viz. :—

In the autumn in each year, immediately after harvest, all the hedges and ditches upon a farm of about 500 acres of mixed gravel and clay land are trimmed and cleaned, and the whole consumed in one or more large heaps by charring or smother-burning, great care being taken that the wood, rough grass, and weeds, of which the heap is composed, is sufficiently covered from time to time with earth to prevent the escape of any flame; and as the heaps are consumed, daily additions of a further quantity are made, as much earth being charred as possible. The whole having been thus converted into a well-burnt mass, by which means the weeds and waste are cleared up and the farm made neat, a most valuable heap of material for the preservation and economical storing of manure applicable to root and other crops is obtained at a very trifling cost.

When the heap is cold it is carted and placed under an inexpensive shed made of very rough materials, viz., oak posts fixed into the ground,

with rough larch poles for the plating and rafters. The covering is composed of the chips obtained from the hoop-maker, but the roof may be covered with any material most easily and cheaply obtained. The advantage of chips or straw is, that the covering is warm for the fowls, which are made to roost in the roof, so that the powerful manure from them may be economised and preserved for use.

It is probably well known to all your readers that charred or burnt earth, cinders, ashes, &c., are complete deodorisers, and all offensive substances thrown into the heap become, in the course of a few hours, entirely free from smell. The first shed erected for the purpose above described did not cost more than £5. It was constructed of a few poles with a roof of thatched hurdles put up by a hedge carpenter. This fact is mentioned to show that no one need be deterred from adopting the system by reason of expense. When the ashes have been placed under the shed, all the refuse of the house and premises, which in most cases is entirely wasted, is thrown upon or amongst them. The urine from the house is removed in a vessel kept for the purpose. All the blood and animal refuse, &c., are thrown into the heap, as also the soil from privies, and in the course of a few hours any offensive smell is entirely destroyed. The manure thus made during 12 months has been found sufficient to provide a good and cheap dressing to be drilled in with the root crops, and excellent results have been obtained—as many as 40 acres in one year have been thus manured.

Having by experience ascertained the complete deodorisation of all offensive substances by being mixed with burnt earth, the material has since been used for destroying all unpleasant smells in stables, cow-houses, and pig styes, with entire success. Buildings which would otherwise smell very strongly are rendered as free from offensive savour as any dwelling-room. The burnt earth is placed all over the floors to the depth of about  $1\frac{1}{2}$  to 2 inches, and is occasionally moved up with a pointed tool. All liquids are absorbed and deodorised, the solid portions of the excrements are daily thrown into the adjoining yard. When the burnt earth is fully saturated it is removed to the shed, and another covering is substituted. Not only is all the liquid manure thus secure and economised, but the health of the cattle is better provided for. Although scarcely necessary to refer to the expense of the above operations, it being exceedingly small, yet it may be satisfactory to some to have data from which the cost may be calculated :—

1. The clearing of the hedges and ditches is a necessary work upon all well managed farms, whether the rubbish is burnt or not.

2. The carting into heaps for burning, and the subsequent removal to the shed, is done with the odd horse or pony and an old man.

3. The collection of the refuse and waste of the house, &c., is easily done. The household servants place their portion of the refuse in a vessel provided for the purpose, and the cowman or odd man removes it to the heap once or twice daily.

4. The distribution over the land is done by means of the drill, as any other manure of a like kind is spread.—*Gardener's Chronicle*.

### Hydropathy in the Garden.

We gave our readers some suggestions in a late number, on the importance of Irrigation in the growth of farm crops, and inviting further inquiry and experiment. We now wish to direct the same kind of inquiry to the management of the fruit and vegetable garden.

The application of water artificially appears to have a useful effect on all crops that grow better in moist than in dry seasons. Meadows, for instance, as every one is aware, produce the largest growth of grass when we have plenty of rains, and are light when the early part of the season—the period of most rapid growth—is dry. Farmers are familiar with the fact that wet swales give a heavier crop of grass, than dry knolls. And some have witnessed examples where the streams from clear springs, flowing in a slow current downward over meadow land, have marked a heavy growth on this watered streak. Rain or spring water, clear or turbid water, will always increase the growth of grass, if not in excess. (Wet, cold, water-soaked places, are often observed to give little else than coarse or sedge grasses—and they furnish examples of the evils of excess). An example is familiar on our own grounds where a meadow lay between the fork of two large creeks—partly flats and partly upland. One stream was always very turbid at the time of high water, the other clear. That portion of the meadow washed by the former was uniformly the heaviest, yielding usually three tons of hay per acre, and often more; the other about two and a half. The higher land, similar in quality, but not overflowed, yielded rarely over half a ton, and the line of demarcation between them (the line between the flowed and unflowed,) was as distinct as possible. The whole proved conclusively the benefit of water alone, and the superior benefit of a thin deposit annually of simple mud, which had no fertility in itself greater than other soil.\*

These remarks do not however apply to the subject in hand, for heretofore to illustrate general principles. We may add, that discrimination is essential in watering different crops. The wet

swale, for example, which will afford the heaviest grass, may produce the poorest corn; yet there is still a certain amount, but much less quantity of moisture essential to corn, for it may be parched and dried by extreme drought.

All vegetables which will receive high manuring, are improved by irrigation—such for instance, as celery, asparagus, rhubarb and cabbages. But the amount must be determined by judgment or some experience, and vary with the nature of the season. All who are familiar with the culture of the strawberry and raspberry, will remember the reduced size and inferior quality of both these fruits when a severe drought has occurred during the time of their ripening. We have known a heavy rain at such time, to double the size of the ripening Franconia raspberries, in two or three days. We have also seen ripening strawberries, placed accidentally under the slow drip of a water cart, doubled in size in twenty-four hours. The artificial watering has this advantage over the irrigation of rains—in being accompanied with no exclusion of warmth and sunlight—an exclusion usually attendant on natural watering, and rendering some of these fruits sourer and less palatable in wet seasons. As a general rule, fruits of a high and concentrated flavor are rendered more pleasant by the diluting which they receive by irrigation; and seedy fruits, as some kinds of raspberries, are rendered more pulpy in the same way.

A late number of the Boston Cultivator contains an account of some experiments reported by Artemus Newell, of Needham, Mass., to the Norfolk Agricultural Society, on irrigating strawberries growing in a pear garden. A few acres of dry gravelly ridge were planted with dwarf pear, nine feet apart. Between each row, a bed for strawberries was formed, by back-furrowing very deep to the centre, thus making the bed three feet wide, with a furrow between each bed and row of trees, for the water to run in when needed. The water was let into a main channel which passed on the higher side and nearly at right angles to these rows. Between this channel and the rows a plank was placed, set on edge, with a hole bored for each furrow between the pear rows and strawberry beds. A cork placed in each hole regulated or excluded the water at pleasure. The water passed off at the lower side, and irrigated a meadow.

The results were, the pear trees made twice the growth of wood when well irrigated. The difference in the luxuriance of the trees could be seen at a long distance. "The best trees are where there is irrigation on the surface, and drain pipes laid directly under them, four feet below." We copy the statement of the mode of planting the strawberries, and the effects of the water upon them:—

"Strawberries I plant between the rows of pear trees, in deep, light beds three feet wide only. By this arrangement the soil is never

\* The same principle,—the benefit from a thin surface coating of soil on grass, has been proved by scattering fine soil over the surface artificially. Farmers are familiar with the strong and early growth of grass along the borders of corn and other cultivated fields, where earth has been scattered accidentally in turning the harrow or cultivator at the ends of rows.

trodden down either in planting, weeding, trimming, or picking the fruit, and they are much more easily kept from weeds. The beds are liberally supplied with strong manure, placed in one deep furrow in the bed, at least one foot below the surface. One row of plants is set directly over the manure, the plants fifteen to eighteen inches apart. They are set in the month of May. The hole for the plant is made with a tool like a marlin-spike, reaching down well into the manure. The roots are let down and the hole is carefully filled with fine earth without pressing, then soaked with water, and dry earth placed over the top to prevent baking. The effect of placing the manure so deep, is to carry the roots of the plant through the manure to the soil in a dry time, to entirely cover the beds by autumn with the most vigorous plants, and to keep the seeds of weeds and grass so low that they will do no harm. The fruit is mostly grown on the new plants, which have derived their vigor from the manure chiefly through the roots of the original plant, the runners of which are cut off in the spring for the purpose of weeding, &c.

Most of my strawberry beds are watered liberally by a constant flow of water along the channels, which have been described. The results are, that the berries are large and fair; they do not ripen quite as early, but continue in bearing much longer; the crop is certain, even in the driest seasons, when those on dry land are cut off—sometimes before half the crop is matured. In fact, I deem irrigation almost indispensable for the successful cultivation of strawberries in dry seasons."

The irrigation of the meadow doubled the amount of hay.

We may remark in conclusion, that while Irrigation cannot supply the place of manure and good cultivation, it will doubtless prove an excellent auxiliary, where it is practicable to introduce it; and so far as gardening is concerned, deep and enriched soil, and thorough and mellow culture, will go far towards preventing the effects of drought, where irrigation cannot be introduced. A combination of both would, if managed with judgment, produce excellent results.—*Country Gentleman*.

### Short-horns in France.

The short-horn breeders in England have every reason to be satisfied with the Poissy show—not that their herds were by any means well represented, but that no show in France has yet so thoroughly established the utility of the Durham breed as the last. Not only was every intelligent spectator convinced of the valuable results which had followed the introduction of foreign blood, but it was plain to them a continued importation is as essential to the

maintenance of the results as the original importation was to their inauguration.

The trade has now risen to considerable dimensions. The managers of the Government Dairy Establishments of Pin (Orne) and du Champ (Mayenne) were amongst the first to try the milking qualities of the breed. After this private enterprise commenced a spirited competition for pedigree short-horn cattle, the honour of the initiative belonging to M. le Marquis de Torey (Orne) and M. de Behague (Loiret). These gentlemen, however, were neither of them well placed to give much of a lead to public opinion: for one resided in a very backward neighbourhood, where the farmers had neither spirit nor money to follow a good example, and the other was placed in the vicinity of an indigenous breed, whose esteemed character rendered any effort to displace it most unpopular. In the departments Mayenne and Maine-et-Loire lying west of the great Oolitic basin of Paris, and composed generally of old red sandstone and granite rocks, this breed has made more way. Whether it has done so because the farming is better and the root crop is more attended to, or whether the improvement in culture has been the consequence of its introduction, it is difficult to say; it is sufficient to remark that these departments have lately made great progress, and that the Durham cattle have well nigh driven out the Mancelle, a local breed, or absorbed it, and are now to be found as much at home in the homesteads of the mere farmers as they are in some of the most thrifty parts of England.

It must not be forgotten that the result is much owing to the enterprise of Mr. Jamet, who, aided by the manager of La Vacherie du Champ, and M. de Falloux, a landed proprietor of considerable repute, and a successful exhibitor at Poissy, has maintained quite a crusade in favour of the Durham. Following this example, the proprietors of Anjou emulated each other, attended our sales, and carried back some of our finest types with which to found the true stock so well represented at Poissy. Attention has been already called in our report of Poissy to the Herd Book of France, with its 1,500 entries, and of the 143 established breeders; but we have yet to speak of the care exercised by these gentlemen in maintaining the purity of their standard. No animal is admitted to a place amongst the upper ten thousand save such as can show a descent on both sides from pure bred stock; both parents must be unexceptionable in their descent, or there is no admission amongst the privileged order for their progeny. This rule was strictly enforced at Poissy; for the jury displaced several aspirants to the peerage because they lacked, on they dam's side, a proof of nobility, and gave them rank amongst a lower, but very large class designated *Croisements divers*. This care is even carried further by the Emperor, who has directed that in future no

short-horn shall be purchased for the Imperial farms whose pedigree cannot be traced on both sides to the second volume of the English Herd Book.

All this precision proving the intense interest which is taken by our neighbours in the race, must, if correctly interpreted, be to the English breeder the source of the greatest satisfaction. Those who have returned from Poissy to tell their neighbours that the French are now so much masters of their business as to need no further tuition from us may be correct; but those who add to this assertion that the perfection of the pure breed of short-horns established across the Channel renders unnecessary any further importation of foreign blood, and henceforth closes our trade in that quarter, must have used their eyes to little purpose, or reasoned negligently upon the facts placed before them.

We know very well in England that no breed of sheep or cattle reaches the same development in the situations to which it is foreign as it does in those natural to it. We know that great mistakes are made in removing stock from one county to another where the circumstances of life differ, or from one side of the island to the other, where the conditions of climate are various. No short-horn breeder is unacquainted with the fact that certain parts of Yorkshire are better adapted to the short-horn than others, and that he is seen in richer bloom in his home pasture than he is anywhere else. It is for this reason that most prudent men when they want new blood like to go north for it. Now, theoretically, if these observations have any force as regards England, they must have much more when applied to France; and, in fact, we find they have. The English exhibited nothing very wonderful at Poissy, but yet the contrast was unfavourable to the French pure Durham. The latter wanted that development which characterised our own. There was nothing, for instance, at three years of age which could compare with Mr. Crisp's ox, or, unsatisfactory as he might be as the only representative in the steer class, with Mr. Holland's steer. We entertain the belief that many years must pass before the short-horn becomes so naturalised in France, should this ever occur, as to render the breeders there independent of a recourse to our herds. Were these gentlemen less particular than they are, ordinary development might suit them; but being so particular, nothing short of absolute perfection will please them, and to obtain this point they must continually return to us for new blood to counteract some certain effects of climate and soil disadvantageous to the growth of the imported breed.

Although the French were unmistakably proud of having accomplished so vast a stride in so short a time, and having arrived at such proficiency in the use of the weapons we placed in their hands, we met no breeder skilful in his art who was not ready to acknowledge, if judi-

ciously questioned, that a pretty frequent accession of English blood was requisite to preserve the French Durham from degenerating.

While, however, this enthusiastic attention to his art tends to make the French breeder a constant and large purchaser at our pedigree sales, it must be remembered that he comes as a discerning purchaser, and that if his custom is to be retained special attention must be here given to preserve the high character of the attraction which draws him.—*Agricultural Gazette.*

### Surface Manuring.

The practice of top dressing, or of surface-manuring, has long been the favorite method employed by all intelligent gardeners within the circle of my acquaintance. We have long ago learned that masses of rich, nitrogenous manures are not what plants require about their roots, but that manures are applied much more successfully (and less injuriously) by top-dressing, either in solid or liquid form. Nature never manures her plants with crude masses of concentrated fertilizing substances, but imparts her stimulating and mineral food in a state of the most minute division—almost infinitesimal!—chiefly from the surface of the earth. No wonder so many fruit trees have been killed, so many grape vines destroyed or rendered barren by excess of wood, in consequence of the heavy manuring at the roots so universally recommended by writers on gardening and horticulture.

The great objection to surface-manuring is founded upon the probable loss of ammonia, caused by the exposure of decaying manures upon the surface of the earth. But this loss has been shown, by sound reasoning and by facts deduced from practical experience, to be much less than is commonly apprehended; while the benefits arising from surface-manuring, in other respects, more than counterbalance any possible loss of ammonia from this practice.

In the first place, when manures are exposed upon the surface of the earth, even in hot weather, decomposition no longer goes on so rapidly as when the same manures are kept in a heap, and the ammonia that is produced is gradually carried into the soil by rains. The other soluble substances, as potash, lime, the phosphates, &c., are of course not lost, because they are not volatile.

Nor are these soluble and valuable substances lost to plants by being carried into the soil before they are needed by growing plants. It has been conclusively shown by eminent scientific authorities that any good soil, containing a fair proportion of clay and carbon, is capable of taking up and retaining effectually ammonia, lime, potash, soda, &c., in a soluble form, so that little, if any, passes off in the under-drainage water of such soils. These substances, it is true, may wash from the surface, but they can-

not pass through a good soil and go off in the drainage water.

By surface-manuring we mulch the ground, and render it cooler in summer and warmer in winter. More shade is an important element in culture—so important that some writers have thought shade alone to be equivalent to manure. A piece of soil heavily shaded by surface-manuring actually decomposes like a manure heap—that is, it undergoes a sort of putrefaction or chemical change, which sets free its chemical constituents, unlocks as it were, its locked up manurial treasures, and fits its natural elements to become the food of plants. Darkness, moisture and air are the conditions required for vegetable and mineral decomposition. These conditions are produced in the soil by surface-manuring.

Then, again, when the surface-manure decomposes, its elements are washed into the soil in a state of solution precisely-fitted to meet the wants of plants, and they become themselves active agents in promoting further decomposition and chemical changes in the entire body of the soil.

Manure, then, I say, chiefly upon the surface. Do not waste your manures by mixing them deeply with the soil. Plant shallow. Keep roots of all trees, plants, and vines as near the surface as possible. There are weighty reasons for the position assumed in the last sentence, which I have not space now to enumerate. I say again plant shallow, Let your soil be deep and dry, but plant near the surface as much as possible. Top-dress your grass, after mowing in July and August, under a burning summer sun; top-dress in the fall, before and during the autumn rains: manure the surface while snow is on the ground, while the March wind blows, and while the April rains fall. Manure your grass, instead of your corn and wheat, broadcast, at any time when you have manure and leisure, and I will guarantee that you will be abundantly satisfied with the result.

To fruit-growers I would say: Do not fill your soil with manure before you plant trees, grapevines, &c. Plant in good natural soil, and manure from the surface, spring and fall, liberally and properly, and I will guarantee you success far greater than if you plant in holes and trenches filled with manures, as the custom is. Surface-manuring and mulching are the true doctrines. I am sure of it.—*Gardeners' Monthly*.

### Natural Food v. Medicine.

What, then, are the medical plants comprised in the natural food of our cattle? What are the medicinal or active principles of such plants? And what are the functions such principles perform in the animal economy?

Owing to the very limited progress which organic chemistry has made in the analysis of the

plants consumed by cattle as natural food, on the one hand, and in the analysis of the beef, mutton, and pork into which such natural food is converted on the other hand, only a very general answer can be given to these three questions, especially the latter two. As to the first the conclusion, in a general sense, is manifest; for as all plants contain medicinal principles, it consequently follows that all the plants eaten by cattle are medical plants. It is only, however, when plants possess active medicinal principles in sufficient quantity to produce certain observable effects upon individual organs—as the kidney, the liver, or any other specific function—that they are acknowledged as medicinal, and are adopted into the *Materia Medica* of the medical profession. Thus, oak-bark contains a large per-centage of the astringent principle, and is consequently adopted into the *Materia Medica*; whereas many grasses contain the same astringent principle, but in so small a per-centage as to be unsuited for medical use, and are therefore not adopted. Along with astringent principle, other barks possess aperient and diuretic properties, as the bark of the ash and elm, and are adopted; but the grasses that contain similar properties, but in small quantity, are not adopted. Again, many of the condimental plants of our natural pastures that are eaten in small quantity by cattle, and relished by them as condiment, are adopted into the *Materia Medica*, because the per-centage of active principles is sufficient to produce specific action. Thus, tansy is a bitter tonic diuretic, and is eaten by sheep, but shunned by the horse and ox. Tormentil possesses even more astringent principle than oak bark and is eaten by sheep and pigs. There is, in short, a long list of medical plants possessing astringent bitter, tonic, aperient, diuretic, and diaphoretic properties, that are eaten, but only in small quantity at a time, the purposes they serve in the dietary of cattle being evidently condimental; indeed, there are very few medical plants that are not comprised in the natural food of our domesticated animals.

With regard to the peculiar functions which the different medicinal principles perform in the animal economy, such as tannic and gallic acid, bitter extractive matter, &c, little is yet known, chemically speaking; but that the all-wise Creator has given them a chemical purpose to serve is manifest from the fact that when the food of cattle is deficient of those principles they lose health, the different organs which are affected by such principles, when present in the food, ceasing to perform their functions normally when such principles are wanting, or are deficient in the food. Until chemistry makes the necessary discovery in the laboratory, so as to be able to solve satisfactorily the chemical question, we must rest contented with the medical solution of the olden time, as acquired by ex-

perience, viz., that those principles that produce cathartic action are cathartic, and are required for some wise purpose in the process of digestion, assimilation, preservation, and defecation in small quantity in the daily food of every animal—that tonic principles are required to keep up the tissues in a normal state of tonicity, so as to enable them to perform their functions. Thus the muscles of the stomach and intestinal canal and the muscles of the heart require tonic principle to counteract the relaxing principles of the respiratory elements of food, so as to preserve their contractile powers at the normal standard; that the kidneys require diuretic properties, the skin diaphoretic, the fluids antiseptic and refrigerant, to prevent abnormal change; and so on throughout the whole list of medicinal properties and their innumerable combinations. Because man is not so well informed in organic chemistry as his Maker is no valid reason for him becoming a sceptic to the chemical solution of what we see daily solved at the bar of experience, in the natural providence of things, and which can be thus solved at the bar of experience as often as we please, in accordance with the established deductions of medical science, especially since the progress now being made in chemical analysis is annually approaching nearer and nearer to a satisfactory solution of the chemical question itself at its base.

In the common language of practical farmers, the medicinal principles of the grasses and other plants eaten by cattle are their odorous and sapid properties. All attempts hitherto made to classify them under such heads as bitter, saccharine, saline, astringent, acid, aromatic, foetid, acrid, alliaceous, musky, &c., &c., have failed. When several of them are combined or present together in one plant, as they generally are, such as saccharine, saline, bitter-acid, and aromatic, it is not very easy distinguishing the one from the other, or saying which may predominate, or how many may be present in one plant. But, with the peculiar smell and taste of such plant farmers are familiar; and also with the fact that the quality of these odorous and sapid properties are very different under different seasons, and under different modes of management and circumstances connected with the harvesting and using of them. They are also familiar with the fact that the value of these plants as feeding materials is dependant upon the fineness of the quality and the largeness of the quantity of the odorous and sapid properties, or natural condiment which such feeding materials contain when given to cattle. There are, in short, no facts in connection with farming that are based upon a more solid foundation than the medicinal properties of the food of cattle, and their dietic value.—*Mark-lane Express*.

Fully one-half of the money value of rape and the best cotton-seed cakes is obtained back again in the manure.

## Agricultural Intelligence.

### Agricultural Exhibitions this Autumn.

#### PROVINCIAL AND STATE.

Upper Canada, at Toronto, September 22nd—26th.

Lower Canada, at Sherbrooke, 17th, 18th 19th September.

New York State, at Rochester, September 30 to October 3rd.

Illinois State, at Peoria, September 29 to October 4.

Ohio, at Cleveland, September 16 to 19.

#### COUNTIES.

Stormont, at Cornwall, Oct. 8th and 9th.

North Simcoe, at Barrie, Oct. 1st.

Brockville, at Brockville, Sept. 18th and 19th.

South Simcoe, at Bradford, Oct. 2nd.

Durham West, at Newcastle, Oct. 9 and 10.

North Lanark, at Almonte, Sept. 16th.

Russell, at Osborne, Sept. 30th.

### Importation of Cattle.

We learn with pleasure that Mr. Simon Beattie, of Markham, who left here for Scotland in the beginning of last winter, has returned with a good lot of picked cattle, and other kinds of stock, for the improvement of the breeds in this country. Mr. Beattie had a very rough and tedious passage out. The weather was very severe and squally, with head winds and a good deal of rain. He left Annan, Scotland, on 14th April, and was nine weeks and two days from that port to Quebec, reaching home from thence on the 21st ultimo. The cattle, however, we understand, fortunately escaped any serious damage. The stock brought over by Mr. Beattie is as follows:

A thorough bred stallion, 5 years old, sired by Grey Plover, gr. sire Irish Bird-Catcher, g. gr. sire Sir Hercules: dam by Corona, gr. dam Repartee by Pantaloon, g. gr. dam by Touchstone, &c.

Two Durham 2 years old heifers, bred by Mr. Robert Syme, Red Kirk, Dumfriesshire, both sired by General Havelock, (16130), and out of pure short-horn dams of Mr. Syme's breeding.

Six head of Ayrshire Cattle, viz: 1 cow, 2 two years old heifers, and two bull calves. The cow and one of the bull calves from the stock of Mr. Anderson, near Ayr; the heifers and the other bull calf from the herds of Mr. McKirdy, and Mr. Hamilton, Lanark.

Thirty-four head of sheep, consisting of 22 Leicester rams, and 10 ewes of the same breed, all from some of the principal breeders in Yorkshire; and two Southdown ewes from Mr. McConnell, Dumfriesshire, bred from the Duke of Richmond's stock.

Of pigs, two sows and one boar of the Yorkshire breed, about six months old.

Poultry, about a dozen of the best Dorking and Black Spanish fowls.

### Adulteration of Manures in France.

The adulteration of artificial manures and guano has attracted the attention of the French government through the efforts of M. Adolphe Bobierre, who has been appointed chemical analyzer of manures for the department of the Loire Inferieure, an institution established by the government. The gentleman has addressed a detailed report, in the highest degree interesting, to agricultural science and to the body of cultivators. He was the first to call the attention of the authorities to the flagrant frauds perpetrated in the manufacture of manures, and to the numberless deceptions to which the trade gave rise. In consequence of his representations, the administration, in order to protect the ignorant and credulous husbandman, founded the institution alluded to, and justly appointed M. Bobierre the first analytical chemist; and the report that distinguished savan has drawn up fully justifies the selection. In it he has laid bare the fraudulent tricks of the manufacturers to deceive both the analytical chemists and the agriculturists. For instance, in the article of animal charcoal, they profess to sell it as containing 40 per cent. of phosphate of lime. They send the article *weighed*, in a dry state, to the chemist, who accordingly finds it contains the alleged proportion. But with the dry material the merchant mixes water, according to the tenderness of his conscience, and then *sells it by the hectolitre (or measure); instead of the kilogram (or weight)*; and thus the buyer and the chemist are both mystified beyond any redemption. But, in order more effectually to conceal the fraud, light, spongy substances, such as carbonized peat and other similar substances, are mixed with the animal black, and absorb the water, making it impossible, without another analysis, to detect the fraud, which, as shown by M. Bobierre, reduces the proportion of phosphate of lime to 19 per cent., instead of 40. We trust this report will be translated into English, and circulated through the agricultural journals, amongst the farmers, who cannot be too much instructed as to the set of harpies by whom they are assailed, in the shape of artificial manure manufacturers.

—Mark Lane Express.

### To Improve Sandy Soils.

The defect in such soils is chiefly of this sort: They are mechanically defective, being so light and porous that they cannot retain moisture, or manure, if applied. Besides, they are generally wanting in various important elements of plant growth. Therefore, to improve them, we must endeavour to supply these radical defects. The first point can be gained by spreading a coat of clay over the surface and dragging it in. This will improve its texture, and will also impart fertility. Adhesiveness and strength having been gained, manure from the barn yard may be applied as fast as it can be procured. Another method is to dress such lands with rough composts. Prepare the heaps at leisure, in the barn-yard. The ingredients may be such as these; ten loads of stable dung mixed with five loads of clayed soil, twenty bushels of ashes, and the same amount of lime. After these articles have been well incorporated, let the mass lie for a month or two; then it will be ready for use. Such a compost, it is easy to see, will be more enduring, and better in all respects, than the same bulk of barn-yard manure. It will improve the quality of the land permanently, and will enrich it with a fertility which will be very lasting. On every farm of the kind here supposed, there should be one or more compost heaps of some sort *constantly* building—*Agriculturist*.

### An Agricultural College Bill in the United States.

The recent U. S. Congress has passed three important acts for the encouragement of agriculture. These are the Homestead bill, the Bill creating a "Department of Agriculture" and the recently passed Bill providing for the establishment of Agricultural Colleges.

The latter bill in brief is as follows. It provides a grant of public land to be proportioned to each State, in quantity equal to 30,000 acres for each Senator and Representative in Congress, provided that no mineral lands are selected or purchased under the provisions of the act. The proceeds of these lands go to the "endowment, support, and maintenance of at least one college in each State, where the leading object shall be, without excluding other scientific and classical studies, and including military tactics, to teach such branches of learning as are related to Agriculture and the Mechanic Arts, in such manner as the legislatures of the States may respectively prescribe, in order to promote the liberal and practical education of the industrial classes in the several pursuits and professions in life." The further provisions of the act are, that the capital of the fund shall remain forever undiminished, and the annual interest be regularly applied to the purpose above

specified; that no portion of said fund, nor the interest thereon, shall be applied, directly or indirectly, under any pretence whatever, to the purchase, erection, preservation, or repair of any building or buildings: that any state claiming the benefit of the provisions of the act, shall provide, within five years, at least not less than one college, as above stated, or the grant to such State shall cease, and said State shall be bound to pay the United States the amount received of any lands previously sold, and that the title to purchasers under the State shall be valid; that an annual report of the doings of each college shall be published, such report recording the improvements and experiments made, with their costs and results, and such other matters, including state industrial and economical statistics, as may be supposed useful, that no State while in a condition of rebellion or insurrection against the Government of the United States, shall be entitled to the benefits of the act; and that no state shall be entitled to the benefits of the act, unless it shall express its acceptance thereof by its legislature within two years from the date of its approval by the President.—*Maine Farmer.*

**WOOL EXHIBITION.**—The Ohio State Agricultural Society has made arrangements to have a great exhibition of wool at its Fair, which is to be held at Cleveland, September 16th to the 19th. —The Ohio Farmer says, "Four classes have been arranged, comprising Felting Wools, Delaine Wools, Cassimere Wools and Combing Wools. In each class there are to be three premiums, of \$20, \$10 and \$5, respectively. None but actual growers are allowed to exhibit, and competition is open to all parts of the United States and Canadas. Samples must not contain less than twenty fleeces. The awarding Committees are partly composed of experienced Eastern manufacturers and practical Western wool men. A capacious building will be erected for the convenience of exhibition, and a wool sale at auction will close the Fair on the Friday afternoon."

## Horticultural.

### Black Wart in Cherry Trees

TO THE EDITOR OF THE AGRICULTURIST.—I have this day cut down about the last of my common tame cherry trees, on account of the fungus or black knot, similar to that which grows on the plum trees. It has killed nearly all the cheery trees in these parts. I would like to know what the cause of it is. Some persons think it is an insect, but on examination I find the suspected insect to be the grub of the curculio, which works into the wart, in the same way as into the plum. But this is not the real cause

of the diseased growth. From whatever cause it arises. I believe it is contagious, for if let alone it spreads very rapidly. I have kept it back for several years, by cutting off the diseased parts. But this spring it burst out on every limb and twig, and there was no other alternative but to cut the tree down. Any information respecting it or how to prevent it would be thankfully received.

R. B. WERDEN.

Picton, C. W., June 1862.

### Florists' Flowers.

The following is a recent report of the Floral Committee of the Hamilton Horticultural Society, which has been handed to us for publication:—

HAMILTON, April 15th, 1862.

*Mr. President and Gentlemen*—Your Floral Committee, in presenting this their first Report for the season, have much pleasure in remarking that they are hopeful, from the favourable winter that has passed, and the preparations that are now being made, that Flora will this year come forth shining in all her beauty and splendour. Your Committee cannot but express the gratification they have in perceiving a greater taste for the finer beauties of nature growing up amongst the people. Although now, as it were, but emerging from the embryo, it will spring up and grow until it embraces the whole land, refining and delighting all minds, beautifying and adorning our country and our homes.

The only flowers your Committee have been called upon to examine are a collection of seedling Cinerarias, raised by Mr. T. Buchanan, gardener to W. P. McLaren, Esq., Oak Bank, in this City. During the past month, and up to the 10th day of the present month, your Committee, at different times, visited Mr. McLaren's green houses, and carefully examined the plants when in flower, blooms of which have been laid before this Club at its meetings during the period alluded to. Those which your Committee have considered worthy have been named by Mr. Buchanan, and described by them as follows:—

*Mrs. MacLaren*, No. 13.—Light crimson, with white ring and purple disc, flower  $1\frac{1}{2}$  inch diameter, good habits.

*Distinction*, No. 14.—Purple self, flowers  $1\frac{1}{2}$  inch diameter.

*Marginata*, No. 18.—White, with dark magenta belt, purple disc, habit good, a beautiful flower.

*Helen*, No. 21.—White, with shaded crimson edging, and purple disc; a fine flower.

*Exquisite*, No. 24.—White, with narrow light crimson edging, purple disc; habits good.

*Standard Bearer*.—White, with maroon edging and plum disc.

*Neatness*, No. 31.—White, with narrow crim-

son edging, and lavender disc; size of flower one inch.

*Perfecta*, No. 32.—White, with crimson edging, lavender disc; habits good.

*W. P. MacLaren*, No. 33.—White centre, broad crimson belt, lilac disc; size of flower,  $1\frac{1}{4}$  inch.

The preceding nine named Cinerarias, are, in the opinion of your Committee, First-Class Flowers, and entitled to a First-Class Certificate, and we recommend the same to be awarded.

Your Committee heartily congratulate Mr. Buchanan in his good luck, and their desire is, that he and all others engaged in the same kind of work may go on and prosper.

GEO. LAING.

### The Pansey.

Read before the Hamilton Horticultural Club by Mr. J. W. Sinclair, Gardener, of that City:

*Mr. President and Gentlemen.*—In attempting to write an article upon the Pansey, I do so with the greatest diffidence, aware of my inability to do the subject that justice it requires, and which it would have received at the hands of one more conversant with its nature, and consequently more competent to give the information such a paper is expected to convey, for the guidance of the amateur and others in the proper and successful cultivation of this flower.

Among the long and still increasing list of florist's flowers, I know of no one more entitled to a prominent position in the flower garden than the Pansey. If we look at its colour, is it not truly excellent? Its form, is it not surpassing fair? While the imagination of the poet is alone capable of picturing its sweet unassuming modesty. It would be a useless waste of your time for me to attempt to trace the history of the Pansey from its obscurity to the prominent position it now enjoys in the favour of all who are interested in the truly ennobling pursuit of Floriculture. Suffice it to say that from having no pretensions to any of those qualities required in florist flowers, viz., size, form, and colour, it has assumed, and in a very marked degree claimed all those properties as its own.

It would be a very easy matter for me to give you the opinion of eminent growers on the best named sorts for competition, or to state their opinion and experience as to the proper mode of cultivation; but as any gentleman present can ascertain all this information for himself I will now give you my own opinion as to how I think the Pansey may be grown to advantage, if not to perfection in this country.

First, select a spot having either a north or eastern exposure, north is best, mark off your bed any size to suit fancy or convenience; I prefer three feet six inches wide by eight feet long: this done, remove the top soil to the depth

of one spade, and keep it close by for future use. Having removed all the loose soil from the bottom you will now proceed to the formation of a new bed; in the bottom place two inches broken stone, upon the top of that throw five inches of old cow manure, adding a portion of the soil already taken from the bed, and thoroughly incorporating the one with the other, (a three flat-toed fork is the best for this purpose.) Now apply a top-dressing of the following proportions, four-fifths leaf mould and one of sand—this done, and your bed neatly dressed, you may begin to plant; this I would do by placing the plants in three rows, at equal distances, slanting the Pansey on the outer rows, and, as far as practicable, a row of selfs in the centre. The plants must now receive a good watering round the roots, and be kept closely shaded for two or three days, when they may be exposed to the morning and evening sun, but not to that of mid-day, more especially when the plants are flowering, else it will either partially extract the colours or cause them to run, a consumption diligently to be avoided. If intended for competition care should be taken to have all suckers removed from the roots, and all flower buds nipt off with the exception of four or five; by so doing, the strength of the plants is not so heavily drawn upon, and much better flowers are obtained. For shading, I would recommend that four stakes be put down at the ends of the bed and a shade of factory cotton attached to a roller suspended between the top ones, with loops so attached that they could be hooked on to the other two. For the protection of the Pansey during our severe winter months, I would recommend a covering of brush or light litter.

To give a list of the best named varieties I think would be useless, as that can be best obtained from the nurserymen known as the most extensive and successful growers. I will merely name one which I think should be in every collection: *Eclipse*—a dark maroon, self-measuring three and one half inches through. A stand containing twenty-four such Pansies could not fail to be a centre of attraction in any exhibition—yet I have no doubt that by following the plan laid down in this paper we may ultimately attain to the same standard of perfection.

### June-Berry as a Pear Stock.

We have heretofore recommended, upon the practice of several eminent pomologists, the use of the June-berry or shad-bush, (*Amelachier Canadensis*), as a pear stock, and from farther evidence we are inclined to believe that it has been too much overlooked, both for this purpose and as an ornamental shrub of itself. It usually attains a height of from fifteen to twenty-feet, and is of graceful form. In the spring it is covered with snow-white flowers, and in autumn

the round purple berries, nearly as large as a mazzard cherry, giving it a beautiful appearance. The berry is sweet, not at all disagreeable to the taste, and we should judge could be easily improved so as to form a most useful fruit for many domestic uses. The berries, as indicated by the common name, are ripe in June, and much before other fruit is in a condition to be eaten.

Our attention has been called anew to this subject by the remarks of Charles B. Ott, a well known nurseryman of Pennsylvania, in the *Agriculturist*, who says he has used this shrub as a stock on which to graft the pear for eighteen years, and after this length of experience is well satisfied with it for most varieties of pears, while other sorts fail after ten or twelve years. The Seckel does very well on a stock of the June-berry, bearing fine fruit. Mr. Ott worked his trees four feet from the ground, but later experiments prove to him that it is best to work them close down, as low as on the quince stock. —*Maine Farmer.*

[We recollect seeing very fine pears growing on the June-berry stock, at a nursery, in the Township of Etobicoke, some thirty years ago. —*ED. AGRICULTURIST.*]

### The Profits of Fruit Growing.

In a report made to the Agricultural Society of Kentucky, we find some statements worthy of consideration.

Four or five years ago, a peach orchardist in Ohio was offered \$18,000 for the fruit on twenty acres of peach trees, while it was yet growing, and more than a month before the period at which the earliest part of it would ripen. He declined the proposition, and realized about \$20,000 from the same fruit by gathering and selling it to customers himself. This, however, was a most extraordinary instance of a good combination of circumstances, viz: fine fruit, a ready market, and high prices. It is one of those happy accidents which occur only once in a very long while. And, besides, four or five years of labor and care had preceded this crop, which was the first borne upon the trees.

Some vineyards near Cincinnati have in favorable seasons, produced nearly \$1,000 per acre; but a much more common yield, one year with another, is about \$250; a sum for about which good land in the Ohio Valley, easily accessible to the best markets, may be bought, trenched planted, (the price of slips included,) staked (with oak) and cultivated to its fourth year. The fourth year brings a crop—though not a full one. Let the avails of this go for interest and contingencies, and the account will then stand thus: Cost of a bearing vineyard per acre, \$250; value of crop, fifth year, \$250. Account balanced. (capital, interest and expenditures for labor being repaid,) and closed.

Within the succeeding five years, the equivalent of four crops may be counted upon. This is equal to \$1,000, which, divided by five, gives \$200 per year as the product per acre. This looks a great deal better than growing twenty bushels of wheat to the acre, or ten barrels of corn. In Washington Co., Ohio, snug little fortunes have been made in raising one kind of apple (the small Romanite, and shipping it southwest for the supply of New Orleans. Strawberry growers near Philadelphia have often pocketed \$500 to \$800 per acre for that delicious fruit. And a plantation of three acres of raspberries on the Hudson river, is stated to have yielded as high as \$1,500 in a single year.

### Domestic.

#### On making Soap.

*To the Editor of the Agriculturist.*

SIR,—I observe in your July 1st number a receipt for making hard soap which I consider of very doubtful utility, for I see no reason why the rosin should be put into the kettle until after the lye is formed, nor is the quantity of salt given, which is important, as too much salt defeats the object. From the following receipt as much or more soap can be made, than from the one you published, and with less material.

Take 6lb. of sal soda, 3lb. of good unslaked lime, put into a kettle, add 15 gallons of rain water, simmer over a slow fire two hours, let it settle, dip off the liquid, clean the sediment out of the kettle and put back the liquid; add 6lbs. of clean grease and boil slowly two hours; after it has boiled one hour add 2lbs. of melted resin and one coffee-cup full of salt, and you will have 30 to 40lbs. of soap. I have tried it, and if properly managed, soap can be made very cheap. If the liquid is simmered in the evening it can settle over night.

I have given the above receipt to at least half a dozen persons, and, with one exception, all have succeeded in making beautiful soap. Cost of material,—Sal Soda, 30 cents; lime, almost nothing; grease, the same; resin, 13 cents.

Yours, &c.,

A SUBSCRIBER.

Brampton, July 11, 1862.

#### Coffee Substitutes.

The love of coffee is an acquired taste. Perhaps nine-tenths of the people using it "burn" it almost to a coal, so that, in reality, any other burnt bitter would answer quite as well. In fact, multitudes in the far West, removed from markets, have become accustomed to use burnt bread-crust as a substitute, which

certainly is not injurious, but it is a known fact that a cup of some mild, hot drink at meals is a positive benefit, while a glass of the purest cold water is as certainly an injury, especially to invalids and to all who do not have robust health.

The following substitutes for coffee have been collected, in all of which it is suggested, first, that the substitute be mixed with the genuine articles, half-and-half; second, that in order to know what you are drinking, roast and grind your own coffee. In this way only can you know that you are not imposed upon, or may not be drinking some cheap material, either filthy or poisonous.

1. It is said that three parts of Rio, with two parts of old Government Java, well prepared, is quite as good, if not superior, to that made of the latter alone.

2. **WHEAT COFFEE.**—Wheat coffee, made of a mixture of eight quarts of wheat to one pound of real coffee, is said to afford a beverage quite as agreeable as the unadulterated Rio, besides being much more wholesome.

3. **RYE COFFEE.**—Take a peck of rye and cover it with water, let it steep or boil until the grain swells or commences to burst, then drain or dry it. Roast to a deep brown color and prepare as other coffee, allowing twice the time for boiling. Served with boiled milk. Wheat coffee probably could be made the same way.

4. **ANOTHER.**—Take some rye; first scald it; second, dry it; third, brown it, and then mix it with one-third coffee and two-thirds rye, and then you will have as good a cup of coffee as you ever drank.

5. **SWEET POTATO COFFEE.**—Take sweet potatoes, cut them fine enough to dry conveniently, and when dried, grind in a coffee mill; dry them by the fire or stove, at this season of the year, or by the sun when that will do it; grind and use one and a half tea-cupfuls for six persons, or mixed with coffee in such proportions as you like. Some omit half of the coffee, some more.

6. **BARLEY COFFEE.**—Take common barley, or the skinless, if it can be obtained, roast as you would coffee, and mix in such proportion as suits your taste. It is very good.

7. **PEA COFFEE.**—It is probably known to many that a very large percent. of the ground coffee sold at the stores is common field peas, roasted and ground with the coffee. There are hundreds of thousands of bushels of peas annually used for that purpose. Those that are in the habit of purchasing ground coffee can do better to buy their own peas, burn and grind them, and mix to suit themselves.

8. **CARROT COFFEE.**—It is recommended by an exchange. Cut up, dry and grind, and mix with coffee in quantities to suit the taste.

9. **CHESNUT COFFEE.**—Chesnuts, also, are said to make excellent coffee.

10. Dandelion root, dried and slightly scorched, never burned.

11. **CHICORY COFFEE.**—Equal weights of chicory and coffee, dried and roasted in the usual manner. The chicory is raised as easily as carrots, and in exactly the same manner. To prepare the root, wash it clean, slice it lengthwise in four to six pieces, according to size, cut in two-inch lengths, dry and keep in a dry place until wanted. Chicory is largely used to adulterate coffee in this country, and especially in Europe, twenty five millions of pounds being used in England and France alone.

12. **EXCELSIOR COFFEE.**—(our own.)—Half a cup of pure, new, farm house milk, and while boiling hot, add to it as much boiling water, and sweetened to suit, call it "coffee," and drink it down.—*Hall's Journal.*

## The Dairy.

### Milk and Butter from Ayrshire Cows.

H. H. Peters of Southborough, who has twenty-seven Ayrshire cows, weighed the milk yielded daily by several of them from the 15th to the 25th of June—ten days. The produce of six was as follows: Jean Armour, six years old, calved May 20th, an average weight of 54 lbs. per day; greatest quantity in one day, 58 lbs. Her milk was set separately for three days, and the cream from it produced upwards of six lbs. of butter of the finest quality. Corslet, five years old, calved June 3rd, an average of 38 lbs. per day. Duchess, five years old, 35 lbs. per day. Miss Miller, six years old, calved April 7th, 36 lbs. per day. Jane, six years old, calved May 27th, 36 lbs. per day. Queen, eight years old, calved February 1st, 34 lbs. per day. Nineteen cows, whose ages ranged from two to eight years, and whose period of calving extended from December to June, averaged 22 lbs. each. The milk from eighteen being set for one day, gave 20 lbs. of butter. Most of the milk is usually sold at the farm. None of the cows were milked more than twice a day, and all, with the exception of three, travelled a mile and a half to pasture and back again every day. Excepting the first-named, which had two quarts of corn and cob meal per day, none of them had anything in addition to pasture feed. Mr. Peters has lately sold two two-year old heifers and a cow, at \$150 to 200, each. They are the first females which he has allowed to leave the herd.—*Boston Cultivator.*

### Butter.

BY CUTHBERT W. JOHN<sup>SON</sup>, ESQ., F. R. S.

The examination of the milk of animals exhibits to us many marvels. We find here the benevolent arrangements of our Divine Author

on every side. It is true that to most of us these are unknown phenomena. Milk is merely regarded by many persons as a useful article in domestic economy: it improves our tea and coffee, it yields us butter and cheese; and that is the ordinary extent of our knowledge. Very few of us have leisure to reflect upon its uses to the young of animals. We often do not consider how that milk supplies the entire wants of the young—he growing calf; how the flesh and bones of the young bovine are all built up as it were by the materials found in its mother's milk, the carbon of the air it respires being also supplied from the same source.

Then again, the *composition* of that milk varies in a marvellous way with the wants of the calf. It is needful, for instance, that the dark-looking matters found in the intestines of the newly-born animal should be removed: to this end, the *first milk* of the cow is found to possess aperient properties. The young calf needs at its birth milk of a better quality than when it has acquired a certain degree of strength. Now let the reader compare in the following table the different degrees of richness of (I.) 100 parts of the milk of a cow in a pasture, examined by Dr. Playfair, with (II.) that of a cow, analyzed by Boussingault, before the calf had been allowed to suck, and mark the far greater richness of the *first milk* of the cow.

|                     | I.<br>Ordinary milk. | II.<br>First milk. |
|---------------------|----------------------|--------------------|
| Casein or cheese... | 4.0                  | 15.0               |
| Butter .....        | 4.6                  | 2.6                |
| Sugar of milk ....  | 3.8                  | 3.6                |
| Ashes .....         | 0.6                  | 6.3                |
| Water .....         | 87.0                 | 78.3               |
|                     | <hr/> 100            | <hr/> 100          |

It was Mr. Lyon Playfair, who some time since drew our attention to the composition of milk, its adaptation to the wants of the young animal, and the materials which it contains to supply every demand of the calf. As he told his hearers, in one of his eloquent lectures on the rearing and feeding of cattle, the casein of milk is precisely the same in composition as animal flesh, and hence supplies the matter adapted for the growth of the body. Its butter and sugar are destined for the support of respiration and the consequent maintenance of animal heat. Butter is indeed a substance admirably suited for the purpose, for it yields much heat by its union with oxygen. Sugar, also, is well adapted for the support of respiration. The ashes or mineral portion of milk consists chiefly of common salt, and the phosphate of lime, or earth of bones. In milk therefore, added Playfair, we find united all the conditions for the life of a young animal. Its rapid respiration, and the high temperature of its body, are supported by the butter and sugar of the milk. The casein

furnishes matter for its growth, and the ashes the materials for the formation of the bones, and the necessary constituents of the blood.

All such facts—and there are many other marvels to be met with, in our researches in the vegetable and animal worlds—cannot fail to stimulate our thirst for knowledge, and excite our gratitude to, and our reverence for their Divine Architect.

It is to only one of the chief constituents of milk—butter—that I propose to direct the reader's attention on this occasion. It is a branch of the economy of the farm, to which more and more attention is now paid. This is a natural result of the increasing demand for our dairy produce. After a considerable interval, the attention of the chemist has been again directed to this important subject. Two able lectures upon milk, and on the production of butter, have been delivered within a very recent period—the first, by Professor Voelcker, before the members of the Royal Agricultural Society; the second by Mr. James Dumbrell, of Ditchling in Sussex, at the April meeting of the Central Farmers' Club. It is some time since any public discussion of importance has occurred on dairy management; and it is a little curious that two lectures should at last have been delivered within a few days, on so increasingly important a theme. The operations of the dairy have not hitherto had the same justice done to them, as other branches of Agriculture. The incessant attention necessary in feeding the cows, in milking them, in the management of that milk and cream when it reaches the dairy, the ill effects upon the butter of only occasional neglect, are all sources of loss, that too often discourage the farmer from keeping a dairy. In fact, like most other pursuits, with care and persevering attention, dairying is a very profitable branch of Agriculture; but, it must be made a part of the never-neglected business of the farm, to ensure success. It was formerly essential that the situation of an extensive butter dairy should be near to populous places; now, however, the increased rapidity and cheapness of railway transit has brought almost all places into sufficiently ready communication.

One of the chief points in dairy management advocated by Mr. Dumbrell, is the tethering of the cows, and the frequent movement of the tethering stake, so as to allow the cow to quite consume the fresh grass without even slightly trampling on her food; for this purpose, the stake is moved in his pastures only about 18 inches at a time, and thus the cow always stands upon turf from which she has already cleared the herbage.

It must be remembered that the Jersey breed, of which Mr. Dumbrell's fine herd is composed, are a singularly docile race, and when he adopted in their case the tethering system, he merely followed a custom universally practised in the Channel Islands.

The management of these excellent lit'e cows in Jersey, was some time since described by Colonel Le Couteur of Belle Vue, in that island. There is no doubt that the soft air and sea breezes of Jersey add to the health of these cows, and to that opinion the Colonel inclines; for he observes, that it is a general opinion that cattle are generally more healthy and more free from epidemics there than in most countries. This may be attributable in some measure to the saline particles which, being so frequently in suspension over the island, are afterwards deposited on the herbage, and tend to its salubrity. After heavy gales, it is frequently found that the grass all across the island has a strong saline flavour. So partial are cattle to this flavour, that they will eagerly devour grass which has been watered with sea-water which they had previously rejected. Two pipes per acre, spread from an ordinary watering-cart, or from a pipe which may be made to pour into a long deal box perforated with holes, will be found of great utility where sea-water or salt can be obtained at a small cost.

"The Jersey farmer treats his cow with gentleness and care; it might be more correct to say that his wife does so. On good farms she is usually housed at night after the end of October to the end of February, if heavy rain, hail, or snow prevail. It is deemed to be healthful to give a cow a short run daily through the winter, excepting in stormy weather. At this season, which is usually several degrees warmer than in the mildest part of Devonshire, she is daily fed with a certain portion of straw, from 10lbs. to 20lbs. of hay, with about 10lbs. to 20lbs. of parsnips, white carrots, turnips, or mangel-wurzel. The grass which she may pick up in the winter, with the above quantity of food, enables her to produce a rich and well coloured sample of butter till within six weeks of parturition. At this period, which is usually regulated to take place about the month of March or April, just when the cow, being in full milk, may soon be placed on the fresh spring pasture in April or May, she is an object of extreme care. On calving she is given a warm potation of cider, with a little powdered ginger. Quayle hints that pet cows are further indulged with a toast in their caudle. The calf is taken from the cow at once and fed by hand. It may be well to advise that on the first occasion of calving, the calf should be allowed to draw the cow fully; for no milking by hand will so completely empty the udder, nor cause the milk-veins to swell to their full development, as will the suction of the calf.

Some of the early meadows produce rich grass in March; but the general flush of grass, which comes on generally late in April, is the period when the Jersey farmer looks forwards with anxiety. The cow is then tethered to the ground by means of a halter five or six feet long: this

is appended by a ring and swivel to a chain, which encircles her horns, closed by a ring and bar; the other end of the halter is fastened to a chain 6 or 8 feet long, which is connected by a swivel and ring to a stout iron stake a foot long; this is driven into the ground by a wooden mallet. The cow having this circular range of 12 feet or more, is compelled to eat it clean. She is usually moved twice a day, and milked morning and evening; on many farms at mid day also.

Under this system, the Colonel owned furcows that produced eight-and-forty pounds Jersey, or above 50lbs. imperial weight, of rich yellow butter per week to the month of May and part of June.

In hot weather, in July or August, it is deemed advisable to shelter cows from the heat and flies; otherwise these tease the cows to such a degree, by forcing them to run about incessantly, that they have no time for repose or for chewing their cud; they, in consequence, afford much less milk or cream.

It was anciently thought that cream from the Jersey cow was too rich for making cheese. M. Le Feuvre of La Hague, who has a fine breed of cows, tried the experiment some years since, and succeeded to admiration. It was made from the pure milk, cream and all, as it comes from the cow. It was found that the quantity of milk that would have produced a pound of butter afforded 1½ lbs. of cheese.

From the quantity of milk which produced a cheese of 20 lb. weight, the *drainings* of the curds and whey, on being churned, yielded 4lbs. of butter. This butter was of an inferior quality when eaten with bread, but was superior to any other for the making of pastry; it was peculiarly hard, and of excellent texture for such use in hot weather (*Jour. Roy. Ag. Soc.*, vol. v. p. 43).

In winter we have seen the Jersey farmers commonly feed their cows with a portion of parsnips, which is a favorite root in that island. In September or October, when the fine aftermath of their pastures begins to appear, from twelve to twenty pounds of these roots given to the cow at milking time produces a fine effect on the cream and fine yellow butter (*ibid.* vol. i. p. 421). In Jersey the parsnip is successfully cultivated on any deep land, whether stiff or light. It is a crop which from its easy cultivation, its freedom from disease and the attacks of insects, might be more extensively cultivated than at present, in many districts of our islands. Parsnips do not appear to be used by Mr. Dumbrell. His system of feeding has been given at length, in a previous page of this volume (see *ante* p.); and in that series of valuable observations he remarks, when decribng his mode of tethering:—"The grass should be eaten so close as to have the appearance of being mown. The cows must be led or have water

brought to them twice a day. The Jersey breed are so docile that a man can lead five or six at one time. By the time a dairy of say twenty or twenty-five cows have been staked over eight acres of meadow land, it will usually be found that the grass upon that part of the field where the first began will be sufficiently grown to be gone over again; indeed, the same ground may be pastured three times in one season, particularly on a farm where the liquid manure is utilized, and which can be used nowhere with so much advantage as following the cows when tethered. Eight or ten acres of fair meadow land will be found sufficient, in an average of years, for twenty-five cows, from the time they leave the stall until after haymaking. A great assistance to this system is the addition of some artificial green crops, as rye, trifolium, tares, &c.; for, during very hot weather, and when fly is troublesome, milk cows are much better under cover in their stalls than out of doors; they should then be tethered during the night and the cooler parts of the day. We suppose that our tethering carries us to quite the end of June or middle of July, and now is the time, just before the growth of the after-grass, when some care is required, and from which time some artificial provision is needed. Backward-sown tares is the best food to meet the difficulty; with this assistance the after-grass may be allowed to get a good head before it is begun. This brings us to the end of July, and the after-grass will carry us well through August, and this is the best month of the whole year for butter-making. Through the month of September mangold leaves will be found serviceable. For the end of September or beginning of October a little hay morning and night is indispensable; and as the weather becomes cold and wet, cows must be taken into stalls at night: lying out in wet weather is detrimental in every way to dairy stock; but no weather is so injurious to the produce of milk, besides being likely to cause abortion or shaking, as white frosts, and the greatest care should be taken that cows in calf should not feed out at that time. White turnips, with the remainder of the autumn grass, will carry us on to the end of November, after which time drum-head cabbage must be provided for at least two months. Cabbage is a very valuable winter feed, as it assists the colour of the butter, and is highly nutritious. Through February and March swedes may be used, and will be found to produce more butter than any other root. During all this winter season a liberal supply of good hay, not heated, is requisite. At the beginning of April mangold comes in, and if the weather is fine, some old grass reserved from the autumn, is very useful, with the addition of spring rape or late-sown white turnips; this, with rye, which must be used sparingly, brings us to our starting point.

To the food of the cow Professor Voelcker

also devoted a considerable portion of his excellent address. There is one error, with regard to cow's diet, which is too common not to render me desirous of briefly repeating, in his own words the result of the Professor's researches. It was when speaking of the effects of oil-cake that he observed (*see ante*, p. 362), that according to theory it would appear that food rich in oily or fatty matter would be extremely useful for producing rich milk, but in practice we do not always find it so. Very rich food has often a contrary effect: it produces by no means, always, a better milk nor a larger quantity; in short it produces fat and flesh instead of milk. Besides the tendency which cows that are good fatteners have to convert rich food into fat, there are some purely practical considerations to be taken into account before we consider the best quality of food which ought to be given to milking cows. It is well known that oily matters pass rapidly into milk. Cows supplied too abundantly with linseed cake produce milk which does not make good butter. A very curious case of this kind was brought under my notice some time ago by Mr. Barthropp. He had milk which furnished cream that could not be made into butter. When put into the churn it beat up into froth; the casein would not separate from the butter. I was informed by Mr. Barthropp that he had given his cows linseed cake in considerable quantities; and this cake, perhaps for want of being mixed with a sufficient quantity of good dry hay, had evidently had the effect of producing too much liquid fat. On trying to separate as much as possible the solid or crystallized fat from the liquid fat, I obtained one-third of solid fat to twenty-three parts liquid fat. In the churn the whole of it made up into a sort of froth. In fact, it could not be churned, the butter remained a liquid even at the cold period of the year at which the cream was analysed, namely, last January. I never before met with another equally striking case, as showing the influence of a great excess of oily food on the quality of cream, and consequently on the butter. In speaking of the quality of cream and more especially the fatty portion of it, I would take this opportunity of remarking that bad oilcake, and particularly bad linseed cake, does a great deal more harm than is generally supposed by dairymen. The inferior taste of the milk of stall-fed cows is well known; but I believe it is not so well known that the wholesomeness of milk is affected by the abominable matters which are occasionally put into linseed cake. Oilcake crushers at the present time seem to have the privilege of incorporating any kind of oily refuse, no matter what it may be, with linseed-cake; and since this has taken place, we have heard more frequently of diseased milk, and of milk which has a disagreeable flavour. Watery food, distillery wash, the acid water of starchmakers, and similar refuse make milk, as

is well known, watery ; and this dispenses with the necessity of mixing it afterwards with water. By far the most common adulterating material is watery food. Water is not so much added to milk as it is incorporated in the animal system before the milk is produced. It is well known that acid water, and especially water that contains lactic acid, has a tendency to produce an abundance of milk. When animals are fed with concentrated food, such as beanmeal or cake, it may perhaps be advisable—in the absence of brewers' grains or distillery refuse, two materials which contain lactic acid—to generate some lactic acid by keeping barley-meal for some time in contact with water, and by letting it slightly ferment, perhaps with some vegetable matter, which has a tendency to hasten the formation of lactic acid from barley-meal. By doing this, I am inclined to think, concentrated food like cotton-cake, or bean-meal, or rape-cake, would be rendered more digestible—more readily available for the production of milk of a good quality.

The owner of a dairy will do well to compare his practice with that of Mr. Dumbrell, and with the valuable chemical inquiries of Professor Voelcker. It is more than probable that the information he will obtain will well repay him for the time he employs in the study. The butter prepared in different districts of England we are all aware, widely differs in its quality ; and yet it is a very reasonable conclusion, that by a little more attention to the dairy and to the pasturage, and artificial food of the cows, the inferior butter produced in several counties may be very materially increased in value,"—*Farmer's Magazine (English.)*

## The Poultry Yard.

### The Best Way to Dispose of Bones.

MESSRS EDITORS :—After reading the various communications which have been published in the *Country Gentleman* on different methods of disposing of bones which accumulate about the premises of the farmer, and converting them into an available manure for agricultural purposes, I will inform your readers how I dispose of my stock of bones. All the bones which are obtained from the meats used in the family, are saved and carried to the hen-house, and deposited there to be used when wanted. Near the bones is placed a flat stone large enough to break them on. At the commencement of winter I begin to break them up, and dispose of them in the following manner:—Laying the bones on the stone, with an old axe, I pound them up fine enough for a hen to eat, and then let my hens eat them. In this way of disposing of bones it requires no sulphuric acid, potash or other costly drugs, which are somewhat danger-

ous for persons to use who are not acquainted with their nature. Neither does it require any fixture to prepare them in, nor time and labor to manufacture the bones into as good manure as any that is made on the farm.

At the present time I do not propose to discuss the comparative merits of the various preparations of bones that are used for manure, neither am I prepared to decide whether bone manure or hen manure is the most valuable for agricultural purposes ; but I am well satisfied as to the value of hen manure for any use that I have made of it. I believe it is an established axiom in agriculture, that the richer the food on which an animal is fed, the richer and more valuable will be the manure. As fresh bones contain much animal matter, as well as phosphates, the manure of hens fed with bones must be much more valuable than when kept in the ordinary way.

But the most profit which I obtain from bones used in this way, is the extra quantity of eggs which my hens produce when fed with the bones. I have found that it is necessary to give my hens a generous supply of animal food, as well as that containing phosphates, if I wanted them to lay well, and other things being equal, the supply of eggs has always been governed by the supply of these articles of food.

As my hens have the run of the farm when the ground is bare, they get a supply of animal and vegetable food, but in the winter season they must be furnished with these things from other sources. I think there is no one thing that furnishes a larger proportion of egg-producing food than fresh bones, as there is always more or less animal substance adhering to them. By making a little calculation with my bones and other animal offal, I give them this food several times a week during the season that they cannot get to the ground. Since I commenced feeding my hens in this way, the average weekly production of eggs has been full as large through the winter, as during any other part of the year. The price at which eggs sell for in this vicinity, is generally one-third more in the winter than in the summer, so that when the eggs are sold it makes a considerable difference to what it does not to have any eggs through the winter, as is the case with many who keep hens, and to sell what eggs are disposed of in warm weather, at the low prices which generally rule at such times. The past winter I kept fifteen hens. Early in the spring, a neighbor, on being told that my hens had laid nearly fifty dozen of eggs since December last, said, that his "hens had not laid an egg then, that he had not commenced feeding them yet to make them lay," their principal food previous to this being boiled potatoes and oats—thus showing conclusively in this instance, that hens must have the right kind of care and food to make the keeping of them pay well.—C. T. ALVORD, in *Country Gentleman*.

## Veterinary Department.

(Conducted by A. Smith, V. S.)

### Draught Stallions and their Selection.

Farmers have by this time made choice of the horses to which to put their breeding mares, and such selection has, we trust, been judicious and sensible. The recent reduction in the price of horses ought to direct more attention to the subject, and increase the production of those first-class animals which are always so saleable at remunerative prices. There is certainly no department of farm management in which the penny-wise and pound-foolish system is more frequently exhibited. Male animals with faulty pedigree, of shapeless appearance, and with obvious hereditary defects are too often used, simply because they are of convenient access, or the price charged is somewhat lower than for more perfect animals. It is too frequently forgotten that in breeding, whether horses or cattle, the first outlay for the use of the sire is but a small item as compared with the subsequent cost of rearing. The extra sovereign for the use of the superior horse is surely well bestowed when it adds in three years four or five pounds to the price of the progeny if he is a cart colt, and possibly double or quadruple the amount if he be a hack or a hunter.

First in importance in the recommendations of a stallion we would place his pedigree. In horses for the turf, and in the breeding of the best Arab steeds, the descent of both sire and dam receives primary attention, and should not be less important in the farm horse. By using animals which have been carefully and judiciously selected for several generations, we obtain good qualities that by repetition and transmission have become firmly impressed upon the stock, are less accidental and more permanent, and greatly more likely to re-appear in the progeny. Every breeder of superior short-horns or first-class sheep admits and acts upon this fact, but too often disregards it in the case of his draught horses. In many parts of the country inattention to the breeding of the cart stallion has led to much disappointment and loss. At present we know of several neat, compact, and tolerably good-looking stallions, once in good repute, which have left, from all sorts of mares, a multitude of undersized, shabby, valueless colts, which undoubtedly owe their deficiencies to the half-bred small parent stock from which the parents sprung. This disregard of good descent, operating with two-fold effect when involving both horse and mare is, we believe, the main cause of the notorious scarcity of first-class horses.

We must not be supposed to advise the farmer to place his trust in pedigree only. It can never be accepted in the room of good and useful

qualities which the well-bred cart-horse must in addition possess. Most of those so called 'points' are so familiar to the experienced eye of the practical farmer that they require little notice here. We would only insist at present upon two most important matters, of which the value is scarcely sufficiently appreciated, namely, a stout, short back, and good action. So intimately connected are the several parts of the animal machine that a disproportion in one respect seriously interferes with the general symmetry and harmony, and especially is this the case if the back be long. The ribs will then seldom arch as they should do, the chest is apt to be shallow, whilst the space between the last rib and the crest of the ilium will tell only too truly of weak digestive organs, and want of hardiness and endurance. If any horse proprietor looks over his stables he cannot fail to realize the fact that, whether in the saddle or harness, the cart or the plough, the well ribbed up, short-backed horse is the one for the hard work and the long day. Many farmers overlook or underrate the importance of action in the draught horse. They prefer the straight and upright shoulder to that which slopes and is well laid back. But good action is almost as requisite in the farm horse as in the hack or the hunter. If he can easily and gaily step out at the rate of three-and-a-half or four miles an hour, the walking which constitutes an important part of his daily labor is materially lightened. The importance of this is very notable in the case of coarse, heavy, under-bred horses, such as abound in some of the midland counties of England, and, indeed, are everywhere too numerous. They plod dully and clumsily along, generally finding it work enough lazily to drag an empty dung cart at the rate of about a mile an hour. It is also amongst horses of this unenviable description that we find the round, rough hairy, greasy limbs, the short pasterns which predispose to ring and side bones, and the flat, brittle feet which so seriously interfere with the usefulness of any animal intended for work upon the roads.—*N. B. Agriculturist.*

### Condiments.

The veterinary profession must feel an interest in the great agricultural questions of the day, and especially in all those that concern the management of stock. We devote upwards of sixteen pages of this number to the report of a meeting of the Royal Agricultural Society, at which cattle condiments were fully discussed. We have one great objection to the discussion, and that is, that Mr. Thorley has had the benefit of a gratis advertisement, for which he could well afford to pay several thousand pounds out of the extraordinary price he induces the British farmer to pay for his medicine. It is a great thing for a dealer in a specific to get a Mr. Beale Browne with his pile of letters, and Ma-

for Munn with his conclusive facts. These gentlemen have done for Mr. Thorley what hundreds and thousands have hitherto done before them for infallible pills and ointments which purify "the tree of life." The recent meeting in Hanover-square affords a striking contrast to the intelligent manner in which such subjects are taken up on the continent. The subjects there are tested by scientific commissions. The Danish government, we believe, was the first to take up the subject of cattle condiments in a systematic manner, and judiciously-conducted experiments led to conclusions similar to those already published by our illustrious countryman, John Bennet Lawes.

How well Mr. Thorley has succeeded is proved by the manner he has raised himself to the position of a martyr in the eyes of Mr. Beale Browne, and similar judges of fact and character. There are two ways to make money in Great Britain out of medicines and other extraordinary preparations. The one is to give an invaluable article, which soon proves an essential commodity, at a small price. The other is to select an article which will not injure, advertise it to any extent, and charge the public for its extraordinary faith in puffs. Many in this world were never born to think much for themselves, and the advertiser has learned that for this class it is essential to assert loudly enough in order to make it believe anything and buy Mr. Thorley will continue to advertise, many will buy and extol his preparations, but the enlightened and provident farmer will think more than twice before he pays for the pretty pictures at the railway stations, and for which the nice manner in which, as the advocates for the food at the recent meeting said, Mr. Thorley's announcements were displayed.

But we have another view to take of the matter, and this not as the result of a prejudice, but from observation. We were once told that the condimental food was concentrated—that was a wrong statement, and we are now asked to look upon it as Worcestershire sauce to the beef-steak. So far as simple condiments are concerned in their effects on man, physicians are at one in urging their very sparing employment. They are useless to those, who, being healthy, are also moderate in their tastes, and are neither intemperate feeders nor drinkers. When a man eats for eating sake, he forces his digestive organs into unnatural work by cayenne and mustard, which he cannot afterwards dispense with without suffering from dyspepsia.

Salt is the material most universally and necessarily employed to render foods palatable, and to aid their nutritious properties. But in excess salt is also very injurious; and Professor Anderson's recent lecture should not be lightly passed over by the man of science and the man of practice. Professor Anderson's statement and recent experiments on pigs by Mr. Lawes, will receive that confirmation by after-experi-

ence which will tend to keep the condiments in their right place, as good property for advertisers, though bad investments for the stock-owner.

To turn more particularly to the somewhat new view we take of this matter, we must mention that condiments, even in the simple form of common salt, but especially aromatic substances, may often kill. The diseases of cattle in Great Britain are undergoing great changes—Deaths from the results of plethora are now far in excess of deaths from other causes. It is not the poor condition, but the extravagantly high condition, of our stock that we must correct. Splenic apoplexy, liver diseases, and other affections due to feeding, and to food grown on rich soil under a forced system of cultivation, are largely on the increase; and if farmers think the medicine, which the Royal Agricultural Society has now helped to advertise, will have as good an effect in these cases as on Major's Munn's six-shilling sheep and his old horse they will be repaid for their credulity by a high mortality. We have frequently been in a position to confirm the observation made by the late Professor Delafond, that condiment, though no more than a small quantity of common salt, is sufficient to turn to death's side the hesitating balance between health and disease in the plethoric animal.

The motto of the English society is, practice with science; and, in accordance with that, let us not have medicine vendors, whose nostrums are wonderful in the mystery which veils their nature and action, puffed to the detriment of agriculture. No British farmer should pay but for that which he thoroughly understands the composition and properties of. Manures are being rigorously tested; they are being sold with analyses, and adulterations are being rendered more and more difficult. Any veterinary surgeon may, for a guinea fee, furnish Mr. Beale Brown, or any other advocates of condiments, with a prescription which will save him hundreds and even thousands, which he might expend in advertised materials, if he wishes *medicine to improve health* (?) Let the drugs be bought in the cheapest market, with open eyes, and mixed by the most careful of old women, and our extensive advertisers must shut up shop. We wish them that share of the good things of this life which they deserve; but we do protest in the interest of the British farmer, and in defence of British common sense in the sight of the world, against the twaddle-talking in the Royal Agricultural Society's rooms in Hanover-square.

—*Edinburgh Veterinary Review.*

## Miscellaneous.

### Paraffin, or Coal Oils

Paraffin—or, as this fluid is frequently termed, coal oil—has been, for some years past, largely used as an illuminating agent. The cleanliness and the economy of the paraffin lamps, with the brilliancy of the light produced, has led to their very general adoption, especially in those places where the conveniences of gas have not as yet been made available. Paraffin, and, indeed, all the varieties of the oils which are sold under this name, are, like it, compounds of carbon and hydrogen. They are produced by the distillation, at carefully regulated temperatures, of coal, of certain carbonaceous shales, and the different varieties of petroleum which are now so largely obtained in America and in Asia. As we have said, from whatever source derived, these oils are hydrocarbons, and, according to the temperature at which the distillation is effected, there result heavy or light oils, as they are termed by the manufacturers. These oils are of variable specific gravities, and their boiling points range all the way from 46 degrees to 600 degrees Fahr. Hence it is that explosions have arisen from the improper admixture of the lighter oils with the heavier ones. In some cases this has arisen from insufficient purification of the oil for burning, and in others (which include by far the larger number of cases) by the mixture of volatile oils obtained from other sources with the less inflammable oils distilled from coal. In the early stages of this manufacture, Cannel coal was almost exclusively used as the oil-yielding material; but since the discovery of the oil wells of Pennsylvania and other places, petroleum has, in a great measure, supplanted the use of coal, some establishments using the natural oil alone. The object of this is readily appreciated. The petroleum being naturally in a liquid state, there is no necessity for a preliminary distillation, as in the case when coal is used, in which event the crude oil must be first produced by exposing the coal to distillation at a low heat, and the resulting product be treated in the same manner as the oil already formed in the wells. By the use of petroleum the retorts for the first distillation are dispensed with, and thus a saving is effected in apparatus as well as in time and labour. When petroleum alone is used in the manufacture of kerosene oil the product contains a much larger proportion of volatile hydrocarbons than when coal is wholly or partially employed, and, therefore, more precautions are necessary, and greater labour is requisite, to effectually get rid of these dangerous substances. Some manufacturers not only neglect to remove these volatile compounds from the oils, but actually purchase the light oils from more conscientious refiners, in order to mix them with heavy oils to make them burn. This is

an exceedingly reprehensible practice, and deserving severe punishment; for the heat generated by the heavy oils in burning vaporises the volatile portion, and renders it liable at any time to explode. The oils distilled wholly from coal, or those with which but a small portion of petroleum has been mingled, are much more easily freed from dangerous portions. By a careful refining, and after distillation, steaming, and a large surface of atmospheric exposure, every dangerous compound can be removed, and no fear need be apprehended from oils which are known to be subjected to a rigid and conscientious refining. In purchasing oils, however, nothing should be taken for granted. They should be carefully tested, and their liability to explode fully investigated. The simplest and most satisfactory test of safety is to place the oil in an open dish in a water bath, and heat it up to 130 deg. to 140 deg. Fahr. If, when elevated to this temperature, and applying a match, it does not ignite, it may be pronounced very safe. If it ignites but slowly or sluggishly it is safe. But any oil that lights quickly in an open dish, at a temperature below the 130 deg. Fahr., may be considered as dangerous. We have seen oil the vapour of which ignited with a smart puff or explosion at 60 deg. Fahr., on holding a lighted match more than one inch above its surface. This was dangerous in the highest degree, and the vendor of such a compound should be held to strict accountability for any accident occurring from its being burnt in lamps. The extensive use of these oil-lamps among the working classes induces us to call special attention to this very simple test. To those who may not be provided with a thermometer to measure the temperature, the following simple rule may be adopted;—Pour into a basin a pint of boiling water, and allow it to stand to cool for five minutes, then pour some of the paraffin oil into a teaspoon, and having floated the bulb of the spoon on the hot water, leave it at rest for a few minutes; then hold a lighted match a little above the spirit; if it ignites quickly, it is dangerous; if not at all, or very slowly, the paraffin may be used without fear of accident. A metallic fountain or reservoir should always be avoided in using any of those hydrocarbon oils. To show the vast difference of the oils now on sale as paraffin oils in this country, Dr. R. Angus Smith, F. R. S., of Manchester, an eminent chemist, has lately found that oil made by Mr. Young, the inventor, and his partners, from coal, and who have really the only right to call their oil paraffin, will not ignite in an open vessel at 154 deg. Fahr.; while a sample of American rock oil, sold as paraffin, exploded at a temperature of 46 deg. Fahr.—*Mining Journal*.

Nine-twentieths of the flesh-forming matters are stated to be found again in the manure of animals fed upon oil-cake.

**ROOT CUTTER AND CLEANER**—A writer in the *Country Gentleman* says :—When potatoes are fed whole, or other roots are cut coarsely, the animal is obliged to hold its head so high to keep the root in contact with its teeth, that gravitation alone will pass it to the gullet, and ordinary it will pass thence unchewed, if not too large but if cut properly and mixed with cut stalks; straw or hay, as they always should be, they will be eaten with the head down, as in eating grass, and consequently be more thoroughly masticated and mixed with other food, and all danger from choking is wholly avoided. Hence the preventive that I have used for five years, and recommended to others to use, is, to cut up the vegetables as finely as possible with a good root cutter and cleaner.

### Pictures from Memory.

The mind of every man has its picture gallery—scenes of beauty or magnificence, or of quiet comfort, stamped indelibly upon his memory. More than half the exile's recollections of home are a series of landscapes. The poor untaught Highlander carries with him to Canada pictures enough in the style of M'Cullough to store an exhibition room—pictures of brown solitary moors, with here and there a grey cairn, and here and there a sepulchral stone—pictures, too, of narrow secluded glens, each with its own mossy stream that sparkles to the light like amber, and its shaggy double strip of hazel and birch—of hills, too, that close around the valleys, and vary their tints, as they retire, from brown to purple, and from purple to blue. He carries them all with him to the distant country. The gloomy forest rises thick as a hedge on every side of his wooden hut; the huge stumps stand up abrupt and black from amid his corn, in the little angular patch which his labor has laid open to the air and the sunshine. These are the objects which strike the sense; but the others fill the mind; and when year after year has gone by, and he sits among his children's children a worn-out old man, full of narratives about the brown moors and the running streams of his own Scotland, his eyes moisten as the scenes rise up before him in more than their original freshness; and he tells the little folks as they press around him, that there is no place in the world that can be at all compared with the Highlands, and that no plant equals the heather. One of Wordsworth's earliest lyrics—a sweet little poem which he gave to the world at a time when the world thought very little of it, though it has become wiser since—embodies a similar thought. The poet represents a poor girl—originally from a rural district, who had been both happier and better ere she had come to form a unit in the million of London—passing in the morning along Cheapside, when a bird, caged against the sun-

ny wall, breaks out in a sudden burst of song. Her old recollections are awakened at the sound; the street disappears and the dingy houses; she sees the meadow tract, with the overhanging trees, where she used to milk her cattle; she sees, too, the cattle themselves waiting her coming; and, in the words of the lyric, "a river flows down through the breadth of Cheapside." Poor Susan! her heart is stirred, and her eyes fill.

Every human mind has its pictures. Were it otherwise, who would care anything for the art of the painter? When standing in front of M'Cullough's exquisite Landscape, I was enabled to call up some of my own—moonlight scenes of quiet and soothing beauty, or of wild and lonely grandeur. I stood on a solitary seashore. A wall of cliffs, more than a hundred yards in height, broken, rose abruptly behind—here advancing in huge craggy towers, tapestried with ivy and crowned with wood—there receding into deep gloomy hollows. The sea, calm and dark, stretched away league after league in front of the far horizon. The moon had just risen, and threw its long fiery gleam of red light across the waters to the shore. A solitary vessel lay far away, becalmed in its wake. I could see the sail flapping idly against the mast, as she slowly rose and sank to the swell. The light gradually strengthened; the dark bars of cloud, that had shown like the grate of a dark dungeon, wore slowly away; the white sea-birds, perched on the shelves, became visible along the cliffs; the advancing crags stood out from the darkness; the recesses within seemed, from the force of contrast, to deepen their shades; the isolated spire-like crags that rise thick along the coast, half on the shore, half in the sea, flung each its line of darkness inwards along the beach. A wide cavern yawned behind me, rugged with spiracles of stalactites, that hung bristling from the roof-like icicles at the edge of a waterfall; and a long rule of light that penetrated to the innermost wall, leaving the sides enveloped in thick obscurity, fell full on what seemed an ancient tomb and a reclining figure in white—sports of nature in this lonely cave. There was an awful grandeur in the scene; the deep solitude, the calm still night, the huge cliffs, the vast sea, the sublime heavens, the slowly rising moon, with its broad cold face! I felt a half-superstitious feeling creep over me, mingled with a too oppressive sense of the weakness and littleness of man. Pride is not one of the vices of solitude. It grows upon us among our fellows; but alone, and at midnight, amid the sublime of nature, we must feel, if we feel at all, that we ourselves are little, and that God only is great.

The scene passed, and there straightway arose another. I stood high in an open space on a thickly-wooded terrace, that stretched into an undulating plain, bounded with hills. The

moon at full looked down from the middle heavens, undimmed by a single cloud; but far to the west there was a gathering wreath of vapor, and a lunar rainbow stretched its arch in pale beauty across a secluded Highland valley. A wide river rolled at the foot of the wooded terrace; but a low silvery fog had risen over it, bounded on both sides by the line of water and bank; and I could see it stretching its huge snake-like length adown the hollow, winding with the stream, and diminishing in the distance. The frosts of autumn had dyed the foliage of the wood; the trees rose around me in their winding-sheets of brown, and crimson, and yellow, or stretched, in more exposed openings, their naked arms to the sky. There was a dark moor beyond the fog-covered river, that seemed to absorb the light; but directly under the nearest hill, which rose like a pyramid, there was a tall solitary ruin standing out from the darkness, like the sheeted spectre of a giant. The distant glens glimmered indistinct to the eye; but the first snows of the season had tipped the upper eminences with white, and they stood out in bold prominent relief, nearer, apparently, than even the middle ground of the landscape. The whole was exquisitely beautiful—a scene to be once seen and ever remembered.—*Essays by Hugh Miller.*

**PLANTED BY NATURE.**—Some seeds when ripe are provided with hooks made to catch hold of passing animals, which after a time, get rid of them by rolling on the ground. Those seeds which are surrounded by a succulent pulp, and are swallowed by birds and quadrupeds, are generally favourably consigned to the earth. Most seeds pass uninjured through the stomach and intestines of all animals, with the exception of gallinaceous fowls. Currant seeds, after having been eaten by man, can germinate. Foxes sow seeds of the cranberry (*vaccinium*) after eating its red berries. Apple and pear trees are often found in ditches and under hedges; proceeding, it is said, from fruit which has been devoured by peasants. Farmers are often astonished when, after having, as they think, perfectly prepared their fields, and sown excellent corn, on reaping they find some places covered only with useless oats. In other cases, mammals and birds devour only a portion of seeds while the rest fall and become productive. When the squirrel shakes the cone of the pine tree to obtain the seeds, a great number fall to the ground and are lost to him. The inhabitants of Iceland call a particular sort of nut "rat's nut," from the circumstance that the rats gather them in great numbers, and hide them in the ground. But as the rats are very often killed by one or other of their enemies, the nuts are often left to germinate. Seeds falling into worm-holes are sure to germinate, as well as seeds which drop into subterranean

passages made by the moles to ensnare worms and insects. The hog by tearing up the earth as with a ploughshare, prepares it for the reception of seeds. The hedgehog passes his life in doing the same service.—*Dickens's All the Year Round.*

**FOREST TREES.**—From the manner in which the Germans preserve and improve their forests, our countrymen might take a valuable lesson. At Hohenheim, this forms one of the most important departments of study. The pupils are instructed in the best method of preserving, propagating, and improving their forest trees, while at the same time a proper estimation of the pecuniary and moral value of those productions of nature is instilled into their minds, which must eventually become the common sentiment. Our people must give attention to this subject sooner or later; and every day's neglect of this practical science will entail evils upon us for which years of labor can hardly make amends. We do not as people appreciate the value of our forest. Negligently, carelessly and wantonly, we are destroying them on every side, not considering that in them lies a mine of untold wealth; for the time comes with every people when they can turn their own natural productions to the most advantageous use for themselves; and this law applies as firmly to the trees as to the coals and various mineral ores. The connection and family health, enjoyment and comfort, with a grove of primeval forest trees about the homestead, never entered the practical heads of our fathers; and their sons, true to the example before them, pursued the same suicidal course. Down came the lofty oak and the beautiful maple, leaving the homestead to parch, and the spring to dry up in the scorching rays of the sun.

If there are any exceptions here and there, you will find the value of the farm increased a thousand fold, simply because the trees have let alone; and what if they have been cultivated with proper care? All along the line of the railroad in Southern Germany, I saw acres and acres of forests trees, from ten to fifteen and perhaps twenty years old, planted in rows as regular as corn is with us, and all cultivated in the most scientific manner.

When will our people learn wisdom in this matter. Will they heed the warning of the Old World—listen to the admonitions and counsels of science, and be prudent in good time? Or will they wait to learn it too late from their own experience?—*Feild Notes*

In a soil unmanured the produce was three-fold, the nitrogenous substances being 9.6 and the non-nitrogenous substances 66.7 in 100 parts. In the same soil manured with potato haulms, the produce was five-fold, the nitrogen being 9.6 and the non-nitrogenous 6.5 94 per cent.

**HISTORY OF THE NORMAN HORSE.**—This horse, known as the Crawford horse, was brought from Lower Canada, about 60 miles below Quebec, in March, 1850, when he was three coming four years old, by T. H. Hussey and Alexander Crawford, of Skowhegan, in this State. Mr. C. has kept him ever since. He is therefore fifteen years old this spring. He is of a light chestnut color, and weighs from twelve to thirteen hundred pounds. He has not been trained for trotting, and yet he has gone at our cattle shows in about three minutes. He was sired by the famous horse Trudell, and out of a Norman mare. He has always done a fair business until within a year or two, in which time it has very much increased. His colts are generally well known all over the county, and are all good size, weighing from ten to thirteen hundred pounds, and they are generally smart travelers, and good roadsters. Norman has got more trotting colts than all other horses that have been kept in Somerset county since he has been in the county. His colts have sold for more money than the stock of any other horse kept in the county. In 1859 at the State Show in Augusta, four of his colts took premiums. Brookside, owned by Geo. Gilman, one of his colts, made 242. At the Show of the Central Agricultural Society, of Somerset, the same year, there were eleven horses entered for trotting and eight were young Normans. The famous Harvil colt, a Norman, was matched against the Crockett horse of Bangor, in which the Harvil colt led in three straight heats. Harvil colt was five years old and weighed eleven hundred and seventy pounds and a gelding. He has since been sold in New York for \$2,000. I think Norman took all the purses where they were matched at this Show. At the Farmington Show the same year, two young Normans took the two first purses—Benj. Baker colt, the other by Samuel Jacobs, called White Stockings. Last fall, at Anson, three purses were offered and one bet made, in which three Normans were entered and took two purses and the bet. Last fall, at Skowhegan Show, one four years old mare trotted in three minutes and three seconds, without making a skip. She was owned by Mr. Walker, and raised by H. K. Knight of Cornville.—*Maine Farmer.*

One hundred pounds of red beet contain of real food 10 lbs., of water 89, and ash 1.

One hundred pounds of oats contain of husk 23.7, of starch gum 46.1 of gluten, albumen, &c. 13.7 of fatty matter 6.7.

One hundred pounds of barley straw contain 1.70 of dry nutriment, and 49.81 of heat and fat producers.

### A Thorough Bred 2 Year Old AYRSHIRE BULL

FOR SALE, by Mr. Denison, Dover Court  
Toronto.  
April, 1862.

### THOROUGH BRED STOCK FOR SALE.

**THE SUBSCRIBER** has for Sale Durham and Galloway Cattle, male and female. Leicester, Cotswold, Lincolnshire, Down and Cheviot Sheep; Cumberland and Yorkshire improved Pigs. All imported stock.

GEORGE MILLER.

Markham, June 3rd, 1862.

6t.

### FOR SALE.

**A LOT** of thorough bred improved Berkshire Pigs of various ages.

R. L. DENISON,

Dover Court.

Toronto, Ang., 1861.

### Notice of Partnership.

**THE** Undersigned have entered into Partnership as Seedsmen and dealers in all kinds of Agricultural and Horticultural Implements, under the firm of James Fleming & Co.

JAMES FLEMING,

GEORGE W. BUCKLAND.

### NOTICE.

**JAMES FLEMING & CO.**, Seedsmen to the Agricultural Association of Upper Canada will carry on the above business, wholesale and Retail, at 126 Yonge-st., 4 doors North of Adelaide-street, until next July, when they will remove to the new Agricultural Hall, at the corner of Queen and Yonge-streets.

**JAMES FLEMING** will continue the business of Retail Seedsmen and Florist at his old stand, 350 Yonge-street.

Toronto, January 1st, 1861.

### Seeds! Seeds!! Seeds!!!

**JOHN GEORGE WAITE**

181 High Holborn, London, England.

**HAS THE LARGEST STOCK** of VEGETABLE, AGRICULTURAL, and FLOWER SEEDS, IN THE WORLD, and can supply dealers on better terms than any other whose sale house, as he makes most extensive arrangements with none but experienced growers do produce his supply of seeds, which are raised and grown from stock selected under his own personal superintendence, and as they are all cleaned and picked in his own extensive warehouses by an auxiliary strength of several hundred men and women, kept for that purpose, he is enabled to recommend, with the greatest confidence, every description of Seed offered by him for sale, and he therefore invites Seed Dealers to apply for his Catalogue.

TERMS—Cash, or satisfactory reference  
England.

March, 1862

6t.

## VETERINARY SURGEON.

**A**NDREW SMITH, Licentiate of the Edinburgh Veterinary College, and by appointment, Veterinary Surgeon to the Board of Agriculture of Upper Canada, respectfully announces that he has obtained those stables and part of the premises heretofore occupied by John Worthington, Esq., situated corner of Bay and Temperance streets, and which are being fitted up as a *Veterinary Infirmary*.

Medicines for Horses and Cattle always on hand. Horses examined as to soundness, &c.

Veterinary Establishment, Corner of Bay and Temperance Sts.

Toronto, January 22nd, 1862.

THE  
JOURNAL OF THE BOARD OF ARTS  
AND MANUFACTURES,  
FOR UPPER CANADA,

Is Published on the first of every Month,

**A**T \$1 per annum for single copies, or to clubs of ten or more at 75 cents. per copy; to members of Mechanics' Institutes, and of Literary, Scientific, and Agricultural Societies, through their Secretary or other officer, 50 cents per annum per copy.

Subscriptions payable in advance.

Printed for the Board of Arts and Manufactures for Upper Canada, by W. C. CHEWETT & Co., King Street East, Toronto.

## IMPROVED BERKSHIRE PIGS

**F**OR SALE by Mr. Denison, Dover Court, Toronto.

Toronto, April, 1862.

## The Agriculturist,

OR JOURNAL AND TRANSACTIONS OF THE BOARD OF AGRICULTURE OF UPPER CANADA,

**I**S published in Toronto on the 1st and 16th of each month.

Subscription—Half a dollar per annum for Single copies; Eleven copies for Five Dollars Twenty-two copies for Ten Dollars, &c.

Editors—Professor Buckland, of University College, Toronto, and Hugh C. Thomson, Secretary of the Board of Agriculture, Toronto, to whom all orders and remittances are to be addressed.

## The International Exhibition.

LONDON, ENGLAND, July 3, 1862.

### *Editors of the Canadian Agriculturist :*

Within the last few days I have made a visit to the implements in motion at Battersea, and am now able to assure you that they were a sight well worth seeing. The many machines in the yard of every description driven by steam were surprising and instructive in the highest degree. In a previous letter I gave you some account of the improved threshing machines. I have now seen them at work, and am quite convinced of their excellence. One in particular does its work effectively, threshing, cleaning, bagging, and weighing the grain, and elevating the straw to a height of some 16 or 20 feet in a most expeditious manner. I really hope that some of our ingenious Canadian Mechanics may be here to witness the operation of many of these machines and introduce amongst us the improvements that have been made in most of them. There is a brick making machine capable of making 20,000 of the most excellent bricks in a day, grinding and pressing all at one operation. The tile making machines are also very efficient. A grinding mill with three run of stones is one of the most simple and at the same time one of the most effective mills that can be imagined. Chaff cutters are brought to the highest state of efficiency, and are doing their work at a rate that is far in advance of previous performances in this line.

The many very useful machines at work, illustrate the power of steam in the most complete manner. It is quite impossible for me to describe the many important and excellent inventions, but I shall forward all the catalogues as well as newspaper reports, which contain a great amount of information of a nature to interest your readers.

I went on Saturday to Farningham, a distance of about 20 miles, to see the last days' trial of implements worked by steam, and was much pleased with the manner in which the work was done. There were some five or six makers who had their machines at work. They consisted of ploughs, scarifiers, and a digger. The mode of working has been much simplified by Mr. Fowler, and his machine is admitted to be the best now in use, and in my opinion is very complete. It was his plough and machinery that I described to you at work last week, and I am quite convinced that I did not over-rate its capabilities.

The cultivator is a very capital implement; it works on the balance principle, the same as the plough, has 14 prongs, 7 on each end of the frame. These prongs penetrate the hard clay to a depth of seven or eight inches, are moved at the rate of four miles an hour, and will do an acre in an hour or even less time.

The digger is a new implement; it is the same in structure as the plough, only the mould board is of a different form. The object is to throw the ground up in a rough state, to be acted on by the frost and sun. This was exhibited this year for the first time, and was by many much approved of. One great advantage of Mr. Fowler's over Mr. Howard's mode of working these implements, is that much less rope is required, Fowler's, being simply passed round a large wheel or pulley, both at the engine and anchor, while Howard's rope is at the engine, wound up on a drum. I should state that the rope is made of steel wire and weighs  $2\frac{1}{2}$  lbs to the fathom. The field in which they were working was nearly a quarter of a mile in breadth, there was therefore half a mile of rope necessary in the case of Mr. Fowler's machine, and Mr. Howard's requires double the length. A full report will be out in a day or two which I will send you. I am now only giving my own impressions from the

observations I made, and from conversation with persons of experience. The official report may or may not confirm my opinions.

You will see in the English newspapers the names of other parties who had implements, and competed. The competition at this trial was entirely for the purpose of proving the merits of the machines and implements, as there were no prizes to be awarded. The contest was for the public favor alone. A traction locomotive was on the ground, moving with several cars attached to it, on the common road, from one part to another of the trial ground, and carrying numbers of the spectators. It seemed to be under the most complete control of the driver, and moved in any direction he willed with the nicest precision, turning corners and stopping and starting with more tractability than the best trained horses could have been made to show. The same machines are to be seen at the Battersea Show, careering around a circle of perhaps 60 feet diameter, crossing and passing each other as if they were going through the figure of a lively dance. It is now an established fact that these engines can be used on the common roads of this country, and their use has been legalized. From their great breadth of wheel they rather benefit than injure the roads, and cannot be objected to on that account.

The street railway has had its day here, and is at an end. The last, which extended from Kensington gate to the Westminster Bridge, has been taken up within the last few days. The agent was fined five hundred pounds for persisting in keeping it in operation after he was required by a decree of court to discontinue it. He claimed the sympathy of the public on the ground that it was the peoples' cheap mode of travel. Public meetings were called and handbills posted up with a view of procuring a reverse of the decree, but all in vain. There had been an infringement of the law, and punishment of the parties attempting to set it at defiance must follow. The annoyance to carriages, and the obstruction of the thoroughfare, was the ground of the complaint, which caused the removal of the roads. Large three horse omnibuses have at once taken the place of the street cars, and therefore the public are still accommodated with the means of travelling on the same route, which is a very important one.

The attractions here now are increased to day by the commencement of the great Rifle Match at Wilberdon Common. I hope to attend this one or two days. Between the Rifle match, the Agricultural Show, the Great Exhibition building, the Crystal Palace at Sydenham, and the somewhat novel entertainment of a Dog Show, also going on, there is scope enough for the exercise of the attention of the sight-seers, of whom the numbers congregated here are not small.

The journals of the day contain articles on the marriage of the Princess Alice, just solemnized,

which are worthy of attention from their tone of heartfelt affection and regard towards the youthful Princess. I believe these articles are the true expression of the national feeling, and surely the people are blessed who can with reason entertain such feelings towards the members of the reigning family. That the prayers of millions of pious hearts in this glorious land have ascended to heaven in the most sincere and earnest manner for the happiness of the youthful pair, I do not in the least doubt.

You will perceive that on the 11th instant the crown labours of the jurors will take place. I shall have to remain here until after that date, and will probably attend the review of the Volunteer Riflemen which is to take place on the 12th, after which I shall immediately take my departure from this great city, and visit some few places in the North of England and Scotland, and thence proceed to Liverpool to embark by the steamer that is to leave on the 24th inst. My stay has been prolonged a week in consequence of the two public events above mentioned.

July 10th.

The Battersea Show is now over. I send you some numbers of the *North British Agriculturist* which contain very correct information on the several departments in addition to what I last week sent you. I was disappointed at not seeing more horses exhibited, but the reason given by the Editor of the *North British* may perhaps account to some extent for the deficiency. The season for which the services of the best stallions are required not having terminated prevented their coming to the exhibition. No matched pairs, gig, or saddle horses were shown, which made the show of horses, taken altogether, much below what I, at least, expected to see.

The principal objects of attraction this week are the International Exhibition and the Rifle match. The latter being at some distance and the weather very rainy, does not draw very many spectators; besides, persons soon tire of looking at the firing at long ranges, where none but the markers have access to the targets. I went one day, but as it was wet and uncomfortable I did not stay long. The targets, to the number of about 30, are all arranged on one side of the common, and the spectators on the other, so that it is rather a dull business for those who are not immediately engaged.

The Exhibition, however, attracts its admirers to the number of from 50 to 60,000 daily, and one never tires of visiting it, for after days of examination there is still something to be seen that is interesting and had not been seen before. The Western Annexe, where the machinery is in motion, is exceedingly attractive. The effect of the vast amount of machinery in motion, and doing all sorts of work, is almost bewildering; the hum is inconceivable by those who have not heard it, and yet all seems to work with life-like and

wonderful precision and nicety. One cannot help being astonished at the many proofs of the ingenuity and industry of man in the displays here to be witnessed.

Numbers of Canadians have arrived within the last two weeks. It is said that there is now an addition of a million of visitors to the population of London.

To-morrow the Jurors of the Exhibition will terminate their services by assisting at the ceremony of distributing the prizes. It will no doubt be a grand affair, and there are to be distinguished persons from every country present. The position that would have been occupied by Her Majesty, had her lamented consort been still alive, will be occupied by the Duke of Cambridge. As a juror I shall have to take part in the procession and ceremony, and the day after I shall be at liberty to leave this great city, to make some brief visits to other parts of the country, preparatory to my return home. The weather still rainy. There have not been two fair days in succession since the first of June. Some people are of opinion that there will be a short crop in consequence of so much wet. There is however a difference of opinion on this subject. As there is a great difference in the weather in the various parts of the country, there is a difficulty in forming a correct opinion of the state of the crops. Mr. Prout, who visited his farm yesterday, only 30 miles distant, says he found there had been scarcely rain enough for the turnip crops, yet the very frequent showers were retarding the hay-making very much. There seems to me to be a great difference in the weather this year from what I experienced in 1851. The month of June that year was fine, and appeared to be very little different from the same season in Canada, but this year it is wet and cold almost all the time. I trust that there has been a favorable change in Canada, and that the crops are coming on well.

Yours, &c.,  
E. W. THOMSON.

### "A. World of Itself."

A correspondent in London thus writes to the *Presbyterian Witness* of Halifax, N. S., of the Canadian Department of the Exhibition:

CANADA.

Canada is a world in itself, anxious to make a show and able to do it. The Canadians have bestowed immense pains on their department and have gone to great expense. They have no fewer than four Commissioners here in charge, besides a number of subordinates. Sir W. Logan is here to look to the mineral and geological section, and assuredly he has made the most of it. They have been able by hook and by crook to exhibit about £500 worth of gold; but they carefully lock it up every night in a safe for fear no doubt that if any one were to run away with it Canadian gold fields could

never replace it. There is a strong force of police inside and outside the building, day and night; and this being the case it is no wonder that the over cautiousness of the Canadians excites amusement. The Lumber of Canada is displayed to great advantage in a pyramid whose top reaches not quite to the clouds but sufficiently near them to be alarming. Canada wheat yields only to that of Australia.

The Photograph department is very superior—indeed it is equal if not superior to anything executed in England—especially in *untouched* portraits. Our friends make the most of their magnificent scenery. Here is Niagara in fifty different forms—in oil, in water, in light, in lead, in ink; Niagara with all the bearding icicles and threatening icebergs of winter; Niagara in all the loveliness of summer—in moonlight, in sunlight; from the American side and from the Canadian side. Many other scenes are here in photograph or some other style.

We must confess it—all the lower Provinces together fail to make the impression that Canada easily produces. The space assigned to her is equal to all the rest, and she occupies it well. Her wooden trophy is overdone however, and it is no wonder the *Times* calls for its disappearance. But her minerals, her manufactures, her lumber and timber, her grain—all demonstrate her wealth and greatness. If the Canadians do not become a powerful and opulent people it is not the fault of the country. By a curious oversight, she has no place in the *Official Catalogue* issued by the Commissioners here. No doubt this will be remedied by and by; but it has annoyed the Canadians a good deal. A similar oversight happened with regard to Prince Edward Island.

THE COW.—When George Stephenson, the celebrated Scotch engineer, had completed his model of a locomotive, he represented himself before the British Parliament and asked for the attention and support of that body. The grave M. P.'s looking sneeringly at his invention said: "So you have made a carriage to run only by steam have you?" "Yes, my lords." "And you expect to run on parallel rails, so that it cannot get off, do you?" "Yes, my lords." "Well, now, Mr. Stephenson, let us show you how absurd your claim is. Suppose when your carriage is running upon those rails at the rate of twenty or thirty miles an hour, if you're extravagant enough to even suppose such a thing is possible, a cow should get in the way. You can't turn out for her—what then?" "Then 'twill be bad for the cow, my lords."

### Agricultural Intelligence.

#### Agricultural Exhibitions this Autumn.

PROVINCIAL AND STATE.

Upper Canada, at Toronto, September 22nd—26th.

Lower Canada, at Sherbrooke, 17th, 18th and 19th September.

New Y. State, at Rochester, Sept. 30 to Oct. 3.

Illinois State, at Peoria, Sept. 29 to Oct. 4.

Ohio, at Cleveland, September 16 to 19.

#### COUNTIES.

Stormont, at Cornwall, Oct. 8th and 9th.

North Simcoe, at Barrie, Oct. 1st.

Brockville, at Brockville, Sept. 18th and 19th.

South Simcoe, at Bradford, Oct. 2nd.

Durham West, at Newcastle, Oct. 9 and 10.

North Lanark, at Almonte, Sept. 16th.

Russell, at Osborne, Sept. 30th.

Peel, at Brampton, Sept. 17th and 18th.

North Leeds & Grenville, at Frankville, Oct. 1.

North Ontario, at Prince Albert, Oct. 7th.

East York, at Markham Village, Oct. 9th.

### Meeting of the Board of Agriculture.

The Board met, pursuant to notice, on 23rd ult at the office, Toronto, at 2 p.m.

Present Messrs. R. L. Denison, A. A. Burnham, W. Ferguson, F. W. Stone, Hon. G. Alexander.

Mr. Denison, Vice-President, in the Chair.

The following communications, reports &c., were submitted and read by the Secretary.

Report of the Building committee of the new Agricultural Hall, dated March 28, 1862, showing that according to statements submitted by the Architect, Mr. Sheard, the work originally let by contract would exceed the estimate of \$12,000 by about \$400 or \$500. Certain additional work suggested as necessary, viz: glass case for shop, counter, hoist, iron shutters, gas and water pipes, would amount to about \$1043 more, while the Architect's commission and incidental expenses would bring up the entire cost of the building to about \$14,000. The Committee decided that these additional details should be proceeded with, leaving the question of any additional rent to be paid by Messrs. Fleming & Co., in consequence of additional expenditure for their accommodation, to be decided at a future meeting of the Board. The report also contained a draft of the lease proposed to be given to Messrs. Fleming & Co., of the portion of the building to be occupied by them: Messrs. Fleming & Co., to pay at the rate of \$800 per annum in half-yearly payments, subject to any additional charges that might be agreed upon, as already mentioned, and their occupation to commence on 1st August next.

Report of the Committee appointed at a former meeting to procure suitable buildings for veterinary stables, submitting draft of a lease of premises on Temperance street, the property of Mr. John Worthington, which the committee had agreed to take for the purpose, and had caused a suitable office to be fitted up upon them for Mr. Smith, the Veterinary Surgeon; the Board to pay Mr. Worthington \$200 per annum in half-yearly payments; the lease commencing from 1st January last.

Circular of an association established in the United States, called the "Association of Breeders of Thorough bred neat Stock," for the

purpose of publishing a record of pedigrees, and soliciting the cooperation of breeders.

Letter from Professor Daniel Wilson, dated April 2nd, 1852, on behalf of the Canadian Institute, requesting to be informed whether the Board would rent a part of their new Agricultural Hall on Yonge Street, for the accommodation of that body. In reference to this application Professor Buckland, on behalf of the committee appointed at a former meeting to confer with the Institute, reported that they had come to the conclusion that the Building was not sufficiently capacious to afford the accommodation desired by the Institute.

Letter from the acting Secretary of the Bureau of Agriculture, Quebec, April 2nd, 1862, stating that the six flax scutching machines ordered by the government from Ireland, had arrived, one of them was presented to the Board of Agriculture of Upper Canada, one would be sent for the present to Kingston, and one to London; the other three would be distributed in Lower Canada.

The Secretary stated in reference to this letter that the mill presented to the Board had been received and experimented with, and that at present it was at Newcastle, in West Durham, where it had been lent to parties to scutch some flax grown in that neighborhood.

Copy of Lease received from Mr. Worthington of premises for Veterinary Establishment, in accordance with the Report of Committee.

Copy of Lease granted to Messrs. Fleming & Co., of part of the New Agricultural Hall, in accordance with the report of Building Committee, these two leases, having both been executed and signed by the President of the Board on April 16th last.

Policy of Insurance of the new Agricultural Hall in the British American Insurance Company for the sum of Two Thousand Pounds, at the rate of half per cent per annum.

Letter from the Hon. Mr. Evanturel, Minister of Agriculture, Quebec, July 19, regretting his inability to attend this meeting of the Board.

Letter from the Acting Secretary of the Bureau of Agriculture, Quebec, July 19, 1862, enclosing copy of letter from Mr. W. Wagner, Canada Government Emigration Agent for Germany, asking for samples of Canadian grain and seeds of forest trees to be forwarded to the Prussian Society of Acclimatization.

Letter from the same, accompanying copies of the first and second Annual Reports of the Board of Agriculture of the colony of Victoria, Australia, for the years 1860 and 1861.

Mr. Denison reported that in accordance with instructions of the Board he had taken measures to defend the suit instituted by Mr. Alexander Campbell, of London, for payment of the sum of about \$600 for work on the Exhibition Grounds at that place, as referred to in a letter from his solicitor, submitted to the Board on January 30th last, and which work the Board considered should have been paid for by the Committee, but that the case had been decided against the Board by the court, and he had accordingly paid the amount.

Mr. Denison also reported that he had recently proceeded to the city of Hamilton, to endeavour to collect the sum of about \$20.00 due to the Association from the Local Committee and the Corporation of that city since the Exhibition of 1861, but had not been able to effect any satisfactory settlement.

It was then moved by Mr. Buckland, seconded by Mr. Stone, and Resolved,—that as early in the season as possible, collections of seeds, &c., be forwarded to the German Society of Acclimatization in accordance with the request transmitted through Mr. Wagner, and that copies of documents of this Board, and specimens of products, be also forwarded to the Board of Agriculture of Victoria, Australia, in accordance with the request of that Board.

*Resolved*,—That the County and Township Agricultural Societies, and individuals, be invited to forward specimens of natural products, seeds of forest trees, grains, &c., for the Museum of this Board in the Agricultural Hall.

*Ordered*,—That the Flax Scutching Mill presented to the Board by Government be exhibited at the approaching Provincial Exhibition, and samples of flax obtained for the purpose of showing it in operation.

The Board then adjourned to 9 a.m. to-morrow.

Thursday, July 24, 1862

The Board met at 9 a.m., in accordance with adjournment.

Present: Messrs. Denison, Burnham, Alexander, Stone, Ferguson, Buckland.

Minutes of yesterday were read and approved.

Attention was called to the circumstance that very few County or Township Agricultural Societies give notice of the time of holding their Exhibitions in the Journal published by the Board, as they are required to do by law, and it was ordered that Societies be requested to give such notices regularly in future.

The Board then adjourned.

#### COUNCIL OF THE ASSOCIATION.

The Board met as Council of the Association at 10 a.m.

Present: The same members as above named.

Mr. Denison, Vice-President, in the chair.

The Minutes of last meeting were read and approved.

The following communications, Reports, &c., were submitted and read by the Secretary:—

Letters from W. Armstrong, Esq., Toronto, March 24th, applying for the appointment of Superintendent of the Fine Arts Department of the Exhibition, and also desiring to be informed whether facilities would be afforded for taking Photographs of objects at the Exhibition.

Letter from the Governor General's Secretary, dated, Quebec 19th April, 1862, enclosing copy of a despatch from his Grace the Duke of Newcastle, Colonial Secretary, conveying Her Majesty's Gracious reply to the Address of condolence from the Agricultural Association of Upper Canada at their Convention in January last.

Letter from Mr. R. L. Denison, dated Quebec 28th April, referring to the days appointed for

holding the Provincial Exhibition of Upper Canada this year, the New York State Agricultural Society having fixed upon the same days, which circumstance subsequently led to a different week being selected for the holding of Exhibition from that first decided upon by the committee.

Report of the Committee for preparing the Prize List, submitting a copy of the List as printed in accordance with instructions of the Board.

Letter from Mr. Geo. E. Pell, Bradford, June 12, applying for appointment of Superintendent of the Fine Arts and Ladies' Departments.

Letter from Mr. A. B. Bennett, Brantford, June 27th, enquiring whether suitable facilities would be given for the exhibition of a Steam Saw-mill, and other machinery, in operation on the ground, at the approaching Provincial Exhibition.

Letter from Messrs. Jacques & Hay, Toronto, desiring to be informed whether the Association would compensate them for the new planed floor laid in the Crystal Palace on the occasion of the visit of His Royal Highness the Prince of Wales, for purposes of the Corporation.

Letter from Mr. W. C. Cain, Wroxeter, Co. Perth, desiring to be informed on what terms the privilege of erecting a tent for photographic purposes within the Exhibition grounds will be given.

Letter from W. Edwards, Esq., Secretary of Local Committee, stating that he had notified that Committee to meet the Council of the Association at the Board Rooms this day, at 11 a.m.

On motion it was then

*Resolved*,—That W. A. Cooley, Esq., of Ancaster, be appointed General Superintendent of the Exhibition.

The names of certain gentlemen resident in the neighbouring States were submitted and approved of to be invited to act as judges of cattle at the approaching Exhibition, and a Committee was appointed for the purpose of selecting judges from the nominations of the County Societies for the classes generally.

*Resolved*,—That the President of the Board of Arts, the Vice-President of the Board of Agriculture, Professor Buckland, and the two Secretaries of the Association, be a committee for fitting up the interior of the Crystal Palace.

*Ordered*,—That the amount charged for the exclusive privilege of putting up one photographic tent within the Exhibition enclosure be twenty dollars.

*Ordered*,—That the Committee appointed to fit up the interior of the Exhibition building be also instructed to provide suitable motive power for machinery.

On motion it was resolved,—That His Excellency the Governor General and certain other distinguished persons who will probably be in this portion of the Province next September, be invited to visit the Exhibition.

*Resolved*,—That Mr. W. Armstrong be appointed Superintendent of the Fine Arts department of the Exhibition.

The Council then adjourned, for the purpose

of receiving the local members of the Local Committee, and to hold a meeting of the said Committee.

The Council resumed at 2 30 p m

Present: Messrs Denison, Alexander, Burnham, Stone, Professor Buckland, Hon. D. Christie, Dr. Beatty.

Moved by Hon. D. Christie, seconded by Hon G. Alexander, and

*Resolved*,—That the Local Committee of the City of Toronto be called upon to report to this Board by the 1st of August the state of their preparations for the coming Show, and at the same time to state what quantity if any of the work still remains to be done, and if they have any means at their disposal to do such work.

Moved by the Hon. Mr Alexander, seconded by Dr Beatty, and

*Resolved*,—That the members of this Board having inspected the cattle sheds erected by the Local Committee are of opinion that they have been placed too low for the preservation of the building and comfort of the stock, and should be raised, if possible, before the Exhibition.

Moved by Mr. Burnham, seconded by Mr. Alexander,—That after receiving from the Local Committee the report called for by Mr. Christie's Resolution, a committee of this council be appointed to provide for and erect in a temporary and cheap manner any other accommodation required, and that such committee be composed of the President of the Association, the President and Vice-President of the Board of Agriculture, and Professor Buckland.

*Resolved*,—That the following gentlemen be appointed a delegation to attend the New York State Show for the current year, viz: Messrs. Christie, Burnham, Stone, Denison.

The Council then adjourned.

### The Royal Agricultural Societies' Show in London.

The recent Exhibition of the English Society appears to have been very successful, although in point of visitors it scarcely came up to a few previous years, when the Show was held in the centre of some of the immense populations of the northern counties. The Highland Society suspended its usual exhibition, and large numbers of Scottish Live Stock added much to the interest of the imposing and instructive scene. There was also a considerable number of Foreign cattle, from the different countries of Europe,—We subjoin the following general description of the Show from the *London Agricultural Gazette*.

The first continuous week of fine weather of which the present season can boast has fallen to the lot of the Royal Agricultural Society, and

thus its meeting, which cannot fail of being successful, has been agreeable as well as useful. The earlier days of the show were indeed attended but by very few. A smaller number were present on Monday and on the following day than have attended on the opening days of any of the recent meetings of the Society, but that has no doubt been owing to the knowledge of the usual attendants at these meetings that the yard was to remain open for so much longer than usual, while the unaccustomed "million" beside whom the Society has this year taken up its temporary abode, are probably waiting for the shilling days of the following week; and the Society benefits indirectly if not directly from the comparatively vacant first days of its show by the longer opportunity thus given of making the existence of the Exhibition known among those who are to throng its yards on Monday.

The yards have never before been so attractive. The Implement Catalogue fills 400 pages and describes 5000 agricultural machines; the Catalogue of the Live Stock show fills 150 pages, and enumerates upwards of 2000 animals. There are 250 Short-horns, 100 Herefords, about 70 Devons, 30 Sussex cattle, 14 Long-horns, 27 Norfolks, 11 Welsh, and 9 Irish cattle, 33 from the Channel Islands, 48 of the polled breeds of Scotland, 27 Kyloes, and 70 Ayrshires—a noble show of British breeds. The Horse classes include 260 animals. 73 lots of Leicesters, a score of Lincolns, 92 lots of Ootswolds, 50 Kentish and other Long-woolled sheep, 69 lots of South-downs, as many Shropshires, about half as many West County Downs, 60 lots of Oxfordshire Downs, 13 lots of Dorset sheep, and about 100 lots of Blackfaced Cheviot and other mountain breeds, make up the show of sheep. There are 200 lots of Pigs exhibited, and there are nearly 200 foreign cattle of various kinds.

Whether as a whole, or taken in detail, the Show is altogether unrivalled. Our own leading breeds have never been better illustrated; those of more local interest have never before been anything like so well represented at any English meeting. And to these we have at Battersea to add all the additional interest of many foreign kinds. The scientific man has here a more striking illustration than has ever before been seen at once of the influence of circumstances upon the form and character and habits of an originally common stock—the practical man has here a larger variety and scope from which to choose the live stock best suited to his own particular circumstances—the mere spectator has a more picturesque variety, a greater quantity and a larger field. In particular the foreign breeds and their attendants are a most interesting addition to the ordinary attractions of the show yard. We have the Dutch dairy breed, black and white, and large and course, but yielding abundance of good milk; and the large Swiss dairy breed, also black and white, or

yellow and white, which, with their neck-bells and attendants, are here one of the leading features of the show. The French sorts are represented by (a) the Normandy, a large course particoloured breed, chiefly dark, brindled brown and dun; (b) the Flemish, chi fly red, reminding one in form of Short-horn cows, and in colour frequently of Devons, or more exactly of the dark red Gloucester cow; (c) the Charolaise, a pure white breed of great beauty and symmetry; (d) the Pyrenean, of a light dun or yellow colour; and (e) the little black and white breed of Brittany, of which an unusually large number is exhibited.

Few of the classes, however, are well filled, the exception being the Bretons, Dutch, and Swiss. Of the beautiful white Charolais but three specimens are shown. We add that there are very instructive and good classes of Spanish, and Saxony Merino sheep exhibited. Readers must be referred to the particular reports which will be found in our columns during this and following weeks for a more detailed account of the several sections of the Show. It may however be mentioned here as of general public interest that the stock shown by the Hon. Colonel Hoop, bred at the PRINCE CONSORT'S Flemish, Norfolk, and Shaw Farms, Windsor, have achieved their full share of success. It will be seen that the first prize in the old Hereford Bull Class and in the young Devon Bull Class are taken by MAXIMUS and CROWN PRINCE respectively. The former had been shown as a calf at Warwick, where he took the first prize in his class. His dam *Superb* was the winner of the first prize of her class at Salsbury, and was there sold to H. R. H. the PRINCE CONSORT. CROWN PRINCE, on the other hand, has also been successful before. He was shown at Leeds and took the first prize in the calf class. The other successes which have attended the stock of H. R. H. the late Prince Consort will be found in our prize list. The stock entered from the Prince Consort's Farm by the Hon. Colonel Hood included 5 Short-horns, 9 Herefords, 4 Devons, 1 Clydesdale horse, and 3 lots of the Windsor breed of pigs.

\* \* \* \* \*

The "several thousand pounds" which the Battersea meeting has cost the Agricultural Society, are money laid out most strictly in accordance with the aim and purpose for which the Society was instituted. Nothing is more satisfactorily ascertained than that agricultural progress depends infinitely more upon the demand for agricultural produce than upon any little artificial excitement which a prize or an award of any kind can give. But agricultural progress is the end and object of the Agricultural Society, and how could its funds be better invested than in giving an opportunity to our stock breeders and our agricultural machinists of displaying their unrivalled wares among the great body of for-

eign agriculturalists who are now thronging our metropolis? And so far as we have the means of ascertaining, the opportunity thus given at so much cost to the Society, has been seized. Stock has been sold in large numbers at great prices, and a large sale of implements has taken place. Confining ourselves to one leading feature of the show, we understand that of steam cultivating machinery Mr. Fowler has already sold at Battersea some £14,000 worth, and that Messrs. Howard have disposed of 12 or 14 sets—this being but the beginning of the results in which this show will land them. The meeting cannot fail, we feel sure, of placing the machine makers and the Society on more cordial terms with one another than has lately been the case. A body which sacrifices so liberally of its means for *their* benefit, as being that of English agriculture generally, will command their support. And this great proof of its energy and life which it has thus displayed will strengthen its foundations in the goodwill and co-operation of English agriculturists, where they will lie much more safely and satisfactorily than in having a large balance at their bankers or a large invested property against "a rainy day."

The following are the numbers of the visitors on the several days of the Show and the sums actually received. We understand that the total cost of the meeting exceeds £14,000, so that there is a considerable deficit to be made good by the Society notwithstanding the large receipts on the last five days:—

|                                               | No. of<br>Visitors. | Price of<br>Admission. | Actual<br>Receipts. |
|-----------------------------------------------|---------------------|------------------------|---------------------|

There can be no doubt that the agricultural machine makers have exerted themselves nobly to make use of the great market which the Society has thus provided for them: and as little is there of the great efforts and success of our stock breeders and flock masters. That the Short-horn breeders have been fully alive to the advantages thus offered to them plainly appears from the enormous classes of magnificent animals they have exhibited. How great the advantages within their reach we have endeavoured to

show in some further remarks upon the subject in another column.

The Hereford and Devon breeders too have been wide awake. There never have been finer shows of all our leading breeds, and this is also true of the more strictly local kinds—The Ayrshire, Galloway, and Kyles; the Sussex, Norfolk, and Channel Islands.

Of Sheep too the display has been magnificent. The Leicesters probably have been equalled formerly, and the Southdowns have been equal to anything that has been seen in former years. But look at the advance here made in public estimation by other classes. The immense display of that lordly sheep the Cotswold, owing probably the local indignation excited by an imagined slur thrown on them by the Society, has never been surpassed. Carrying wool which is now of the highest market value, the quantity of surface bearing it—unlike that of the Merino disposed in ugly folds and wrinkles, which are detested on the score of increased quantity of fleece—is spread tightly over one of the best formed carcasses of which the perseverance and intelligence of our breeders can boast. Both mutton (for quantity) and fleece (for quantity and quality) are unequalled by any other kind; and it is well that the spirit of the Cotswold breeders has been called forth to make such a magnificent display as is here exhibited.

The Shropshires, too, are a splendid show, and of some other breeds reports will be found in other columns.

It is impossible to doubt that a collection so multifarious and so large, and in either view extraordinary as the produce of "a little island in a Northern sea," thus displayed before men of all countries, and fully alive to the importance of improving their own agricultural resources, must prove of immense service to English agriculturalists.

#### TRIAL OF STEAM PLOUGHS AND CULTIVATORS AT FARNINGHAM, KENT, UNDER THE AUSPICES OF THE SOCIETY.

We take the following from a correspondent of the *Irish Farmer's Gazette* only premising that the display of implements and machinery in Battersea Park is said to have been unrivalled, both as to extent, quality, and practical adaptation: although no money awards were given on the occasion. This opportunity of bringing their productions before the eyes of the most intelligent and enterprising agriculturists from all parts of the civilized world being deemed a sufficient compensation by the makers.

#### STEAM CULTIVATION AT FARNINGHAM, AND NOTES OF THE SHOW.

"On Thursday, Friday, and Saturday the trial of the different steam cultivators will

take place, at Farningham, Kent; 24 miles from the Victoria Station, London. Trains every hour. This was the announcement in all the journals; it was enough to bring out the agricultural world in force to see a rare and, to them particularly a very interesting sight. So we went. The very first thing that struck us was the great preponderance of foreigners at the station—the Babel of tongues, in which English, decidedly did *not* predominate. A great many were going; the fare was very moderate; and the day, for London, usually fine. The only drawback was the extreme probability of accident, which they manage rather regularly on this line; and as we didn't start for a quarter of an hour after the proper time, we expected *something*, as a matter of course.

Twenty-four miles from London! That is a pretty stretch—that should bring us into the veritable country; far from London brick and mortar. But it didn't; for 16 or 18 miles from the Victoria Station, and it is the great city still. Everywhere along the line you see new villas rising, grounds cut up into building lots, large painted boards on either side with "This freehold to be sold for building; everything done with an eye to its becoming a suburb of London. Occasionally you see dairy or fattening cattle in luxurious old grass; sheep and lambs, almost wholly west country Downs—a large, coarse species, not much known in Ireland, on indifferent pasture, but now and then on clover or vetches, in pens; the hay harvest nearly over, and the country in all its glory. But a doomed country soon to be ran over by the bricklayer. At St. Mary Cray the country begins to appear in its natural state, and for the first time, to the native Irish eye, a strange production; not fields so much so as patches of hops, growing like enormous vines. Tickets, gentlemen—next station is Farningham. We arrive—we see all around the smoke of the steam engines in the fields; we are in haste to be off across the country; when some one discovers a traction engine and three waggons ready to draw us along the way to the working ground. We jump in—off we go, down an incline easily enough, slowly around a sharp corner to the left, and along a level road; painfully and slow up an ordinary, farm wagon way; great whistling of engine, rush and scramble, and we are beside Fowler's steam plough, going steadily, and doing its work thoroughly well. There were three different kinds of Fowler's apparatus on the ground and working, but to my eye there was only *one*; his plough, turning four furrows—*charrue a quatre socs*. Next to him was Howard, of Bedford. The ploughing the same in every particular, and the whole finished in a style that you don't see once in a hundred—not in a thousand—times by hand. It was a most unequivocal success; the machinery moved regularly and constantly. There was not a longer

delay at the headlands than would have been in turning in a pair of horses. The ploughs were as entirely under control as they are in the case of the ordinary ploughman; and, indeed, I think on account of the steadiness derived from their weight, a great deal more so. All I can say, in a word, is that it was as well finished, as thoroughly done work, as any farmer could wish to see. There were altogether ten or twelve engines and cultivators at work, but scattered over a circle of at least five miles. Coleman's apparatus did its work very well, smashing up the soil thoroughly, and rather deeper than any of the others. The Woolston system did not show to great advantage, to me at least; and far in the distance was a novelty indeed—two of the local Kent ploughs working by steam. To any one not having seen them, I may say that the rudest old Irish wooden plough is a neat, handy implement in comparison; but such is prejudice, that a gentleman told me they were wholly superior to any, say of Howard or Hornsby's, and that he himself, farming in the vicinity and on a large scale, after giving a trial to the improved implements of these celebrated makers gave them up and returned to the old style, as being the better one. It may be; but *apropos* one is forcibly reminded of the argument of Paddy-go-Easy in a similar case. The land operated upon, in nearly every instance, was clover stubble, rather tenacious in some places, and rather hard and dry in others—in such a state generally, that it could not well have been turned over with an ordinary furrow with a good pair of farming horses. I like the ploughing. Fowler's as well as Howard's because the *entire* green stubble was turned down, the furrows were firmly pressed together, and, I may fairly say, the ground was ready for the seed at one operation. It does not matter that no grain was about being sown; this to me, appears one of its greatest recommendations, that any surface weeds would certainly be decomposed, shut out from the atmosphere between the hard dressed furrows; whilst in the other—the Woolstonian system, as it may be generally designated—though the land, no doubt, is broken up, the surface undergoes but little change, and if at all dirty, after standing some time would again be growing green. It is no practical answer to say that there *should be no surface weeds*; we will hardly ever attain to that perfection in ordinary farming. But if we did, the land at Farningham was very clean indeed; not the slightest trace of coltsfoot or scutch grass; while you might have *immediately* sown the wheat after the ploughs. I don't see how it could possibly have been done after the cultivators.

These are the ideas of a mere Irishman, as between the two systems. I must say the English farmers seem to be pretty equally divided on the subject; and it would be presumption of the first water for a poor Co. Armagh farmer

"to decide" where such "doctors disagree." All the machines on the ground worked along smoothly; some of the engines moving themselves forward as the progress of the work required; others remaining fixed to the same spot all the day. I prefer the former, though each worked well; but, upon the whole, it appeared to me that a great many more hands—men and boys—were required to attend on any of the machines than we usually read of in the papers.

As a wind up, I may add a few notes on things in general touching the district in which the trial was held. It is almost wholly cultivated; grazing, except in the meadows bordering the Darnet, a beautiful though shallow stream, and here flowing over a pebbly bed, nowhere to be seen. Yet it is a district famous for its sheep; and on the record day (Friday), the Messrs. Russel, of Horton Kirby, sold by auction, just adjoining the station, 100 ram lambs of the west country Down breed, at prices varying from £2 6s. to £6 per lamb, or about a general average of £4 10. No doubt, they were about the finest lot of lambs I ever saw, and their breeders widely celebrated—but think of the prices. They were sold in the field in which they had been penned for a month previous, on vetches; a magnificent crop. The pens are formed by hurdles of wicker work, and are a peculiarity of the district. Each hurdle is, say, 10 feet long, with ribs about two feet apart; they are wrought up with hazel, which abounds in the country; also sometimes mixed with clean whitethorn shoots, and are capitally adapted for the purpose. When not used, they are built up in great square piles, 18 or 20 feet high, at the farm-yard, and carefully thatched over. Nowhere here, in a wide district of country, do the sheep seem to be penned on the Irish and common sense system, of giving them a ridge or so at a time, fresh and fresh; leaving them at liberty to quit the ground on which they feed when they choose. By this means the green food is kept sweet as may be, and they eat it with relish to the last. But here, a square pen is put up, with hurdles all round, the shepherd attends on the sheep constantly, they are put at least 100 to the square rood, and kept on that space till the food is consumed, or rather, till they will eat no longer. I think there must be great waste, and the system entirely of a piece with the ploughs.

The first view of the country, from the Farningham station, is wonderfully like that of the grain growing districts of the north and midland of France, and the soil, too, the very same: the cultivation identical. The hills rise in long sweeps; the incline nowhere so great as to tax the strength of the horses. Wheat, rye, barley, oats, some peas, and rarely, beans; winding along the face of the hills, undivided by any fences. Even parish boundaries are merely marked by an occasional stone: all is cultivated.

The barley on an average is equal to the best in Corly, Louth; the wheat (red) all in drills, generally strong, but thin; the white wheat, without an exception, magnificent. It is generally in flower, and so free of weeds. Oats look very poorly, but in every case I saw sainfoin growing amongst it, regular and strong. This will be cut for soiling for years to come. In mangel wuzel and turnips they are not very forward; but in potatoes, as a rule, it would pay the farmers of that district to send a special commissioner on to the Green Isle, to see how we do it. They have a very fair soil and a warmer climate than we, but they are far behind us in this crop. *En revanche*, I heartily wish our people could see how clean the land in green crops is kept; not a weed of any kind showing, and if they won't have a superior crop of potatoes, neither will they have a most undoubtedly superior one of thistles, coltsfoot, and scutch grass. The assemblage was not nearly so large as might have been expected; indeed, the local attendance was nowhere. Hodge plied the hoe, or stared in vacant wonder at the passers by. You asked him the simplest question, he could only gape out, "Doant kneow, shoore!" and I guess he didn't; but as to curiosity to go see the steam cultivation, he had none, neither had his *measther* the farmer, for decidedly on the ground not half the men were English! Here in their own country on a great occasion, in a great undertaking, so specially affecting agriculture, the great British agriculturist was in most limited supply. In the carriage down to Farningham there were six of us—three Germans, a couple of Yankees, and myself; on the ground the foreign element predominated, and returning in the carriage there were four French agriculturists from Tours, who took it so much as a matter of course, that on nearing London, they asked the name of that plant the Rev. Mr. Townsend recommends so much; and I replied, in Ireland we call it "whins," but in English "furze;" one of them exclaimed, "Holt! ce monsieur donc parle Anglais aussi!"—as if it had been a novelty to hear it during the day at all.

As to the show I don't see any marked advance on the previous years in cattle, except the Herefords—a decided improvement. In the foreign section there are some excellent animals shown; some that threw rather an air of astonishment over the settled gloom on the noble countenance of the great Briton. But the show of sheep was complete—there were such pens shown. The Cotwolds outdid themselves; the Leicesters are, I think, a trifle larger than formerly; the south and west country downs are capital; but chiefest of all the Shrops. Horton has taken the first prize this year, the third time successively; and I believe, from some experience, the blood the best in England, or in Ireland either. Captain Broughton this year again secures the prize ram; and those who

have bred from the Cherrymont flock have had reason to congratulate themselves. As an instance of enterprise and judgment in selection, I may here remark that Mr. Adney, of Harley, Salop, who was so successful with his Shrops, and indeed made a name for them, is uncle to Mr. Horton, of Harnage Grange, a young man already famous; a fame which, while there is every likelihood of its being perpetuated, will do what fame does not always do—make them a fortune. Here, from the same flock, in a few years, two men with judgment, and a rare knowledge of business, have produced some of the most famous and valuable rams in the world. The prize pen of Shrop ewes, of the Messrs. Crane, were universally admitted to be the finest ever exhibited. On the whole, this show has been a decided success to the Shrops, and they deserve it: with which, kind reader, farewell.—CURIEUX, London, 28th June, 1862.

### International Exhibition.

Thinking it will be interesting to our readers we subjoin a list of persons in British North America to whom medals have been awarded or Honorary Commendations made for the articles they exhibited at the Cosmopolitan Show now being held in London. Canada has come out of the severe competition much better than could have been reasonably expected, when it is considered how late we were in commencing preparations and the small encouragement offered by the government. Much praise is due to our Commissioners for the industry and judgment they have displayed in procuring an extensive collection of materials, under many disadvantages that is in the highest degree creditable to the intelligence and skill of our people engaged in agricultural and manufacturing industry.

We learn from the report of the Commissioners, that the number of Jurors engaged in determining the persons entitled to medals and honorary mention, was 612, of whom 287 were foreigners, and 325 Englishmen. Their labours were of no ordinary kind, having extended over two months. The number of articles that they had to examine is set down at 25,000; the number of medals awarded by them is nearly 7,000, and "honourable mention" has been made of nearly 5,300 persons. The proportion of awards is greater than in 1851, but not so large as in 1855. The colonies were represented by jurors recommended by Colonial Commissioners, so as

to avoid the slightest ground of complaint on the part of exhibitors.

## MEDALLISTS.

The Commissioners for Canada, for the display of woollen goods and hand-yarns manufactured in the colony.

The Government of Prince Edward's Island, for a very interesting and varied collection of woollens, mixed fabrics, &c., homespun and made, illustrative of the domestic industry of the colony.

Government of Newfoundland, for a very fine collection of skins in silver cross, and red fox, and otter.

W. Coleman, Nova Scotia, for a very choice collection of skins, fine specimens of silver, red, and cross-fox, otter and minx.

McEwen and Reid, Nova Scotia—sofas, chair, and cabinet of native wood—for excellence of workmanship.

—Snell, of Canada, for good machine-made nails.

—Scrymgeour, New Brunswick, for well-made horse shoes.

Captain R. Gaskin, Kingston, Canada, for a collection of agricultural hand instruments.

Tongue & Co., Canada, for an assortment of edge tools highly finished.

Hon. P. J. O. Chauveau, for the merit of his collection of educational journals and reports.

The New Brunswick Committee for the Exhibition, for their collections of woods illustrating the study of botany.

—Downes, of Nova Scotia, for his collection of animals.

Professor Howe, Nova Scotia, for the excellence of his mineralogical collection.

J. M. Jones, Nova Scotia, for his collection of fish.

J. Mosher, Nova Scotia, for good manufacture of blocks on the Bothway principle.

W. Notman, Montreal, for excellence in an extensive series of photographs.

Captain P. Gaskin, Kingston, Canada, for a collection of agricultural tools.

J. Jeffrey, Canada, for iron plough.

J. McSherry, Canada, for iron plough.

J. Morley, Canada, for iron plough.

J. Patterson, Canada, for iron plough.

Whiting & Co., Canada, for collection of agricultural tools.

New Brunswick Commissioners, for a horse-rake.

J. Brown, Canada, for the excellence of manufacture of hydraulic cement.

G. R. Stephenson, as the representative of his cousin, the late R. Stephenson, M. P., F. R. S., for the extraordinary boldness of conception and the great ingenuity of the construction of the Victoria Bridge, Canada.

Larue & Co., Canada, cast iron hollow wheels, for excellence of workmanship and proved durability.

The Executive Committee of Vancouver's Island, for spar of Douglas pine, 220 feet.

Edward Stamp, Vancouver's Island, for a section of *Pinus Douglassii*, six feet diameter, with roof shingles and other timber specimens.

Blaikie & Alexander, Toronto, for dressed flax.

Andrew Bridge, Canada, for a tub on a new principle of construction, exhibiting much taste and ingenuity.

E. B. Eddy, Ottawa, for machine-made wooden pails and tubs, at exceedingly low prices.

C. L. Ingersoll, Canada, for a cask constructed on a new and ingenious principle, for five liquids.

James Lawrie, Canada, for planks and logs, and 21 named specimens of logs from the Ontario district.

Hugh McKee, Canada, for a scientifically-named collection of 98 of the woods of the colony, accompanied with leaves, &c.

T. Moore, Canada, for a large collection of excellent handles for tools and implements in hickory and other woods.

Nelson & Wood, Canada, for whisks and brooms of Sorghum straw, at very low prices, from 1s. 6d. to 6s. per dozen.

Duncan, Porter & Co., Canada, for 19 very fine square logs of timber.

The Abbe Provancher, Canada, for a very extensive, accurately named and extremely well illustrated collection of the woods of the colony, accompanied with dried specimens, useful information, &c.

Samuel Sharp, G. W. R. R., Hamilton, for a magnificent collection of planks, polished slabs, veneers, and a named collection of 26 specimens, from Western districts.

James Skead, Canada, for a magnificent collection of planks, logs, and a scientifically named collection of 27 woods, all from the Ottawa districts.

D. R. VanAllen, Canada, for planks and logs, all magnificent specimens from the Thames district, and 21 scientifically named specimens.

A. L. Triminski, Canada, for magnificent logs of white oak, rock elm, and hickory.

Miss E. Begg, Nova Scotia, for application of native grass to plaiting and bonnet-making.

Miss E. Begg, Nova Scotia, for very fine samples of flax prepared by dew rotting.

Miss Hodges, Nova-Scotia, for baskets, decorated with pine cones and other hard fruits.

Miss Lawson, Nova Scotia, for a collection of forest leaves of the colony, so prepared as to preserve the autumn tint.

—Pryor, Nova Scotia, for a preparation of the fibre of *melilotus leucantha major*.

Local Committee of Prince Edward's Island—for a collection of wicker work, &c., including excellent flax, well dressed.

Miss E. Jardine, New Brunswick—for ornamental work of native seeds.

D. Munroe, New Brunswick—for an excellent

scientifically named collection of 21 woods, veneers, &c., accompanied with specimens, and a volume of valuable notes and observations.

E. Potter, New Brunswick—for fine carving in a wooden box.

Mrs. D. B. Stevens, New Brunswick—for ornamental work in native seeds.

Campbell and McLean, Nova Scotia, cavendish tobacco. Quality of Tobacco used, and quality of article produced.

Barber, Nova Scotia—salmon and lobster; excellence of quality.

J. Cairns, Prince Edward's Island—salmon and lobster; excellence of quality.

D. Brown, Canada—maple sugar; excellence of quality.

New Brunswick commissioners—spiced salmon; excellence of quality.

S. Knight, Newfoundland—preserved salmon and lobster; excellence of quality.

W. Boa, Canada—for all his samples of substances used for food.

R. L. Denison, Toronto—Indian corn stalks; for extraordinary growth.

W. Evans, Canada—for collections of grains and seeds, excellent and interesting.

J. Fleming, Toronto—for seeds and grains, as excellent and interesting.

B. Johnstone, Canada—for samples of Soule's winter wheat, of excellent quality.

J. Logan, Canada—for spring wheat of excellent quality.

County of Peel Agricultural Society, U. C.—(medal to John Lynch, Sec.) for barley, peas, and two kinds of spring wheat, all of excellent quality.

A. Shaw, Canada—for rye of excellent quality.

County of Beauharnois Ag'l Soc'y L.C., (two medals awarded to growers), for flax seed, grown by C. Burguin, for grass seed grown by C. Tait.

J. Wilson, Canada—for oatmeal of excellent quality.

The New Brunswick Commissioners, for the excellence of their collection of substances used for food.

The Commissioners of Newfoundland, for a fine collection of seeds.

R. G. Fraser, of Nova Scotia, for excellent grain, of garden and field seeds.

Local Committee of Prince Edward's Island—for interesting collection of agricultural produce.

Agricultural Board of Upper Canada—for samples of wheat from various counties of excellent quality.

Agricultural Society of Huntingdon, L. C., (one medal to grower), for peas 40 bushels per acre grown by John Penis.

Agricultural Society of Wellington, U. C., for wheat of excellent quality.

Agricultural Society of Wentworth and Hamilton, U. C., (three medals to growers), for blue

stem wheat grown by I. H. Anderson, for red chaff wheat grown by John Smith, for potato oats, grown by A. Gorie, very superior in quality.

Spurr D. Wolfe, New Brunswick, for products obtained by the distillation of coal.

Executive Committee of Vancouver's Island, For collection of Agricultural seeds.

Benson and Aspiden, Canada, samples of Indian corn starch. For the excellent quality of samples.

Canadian Oil Works, Hamilton, for an extensive exhibition of the derivatives of petroleum.

E. A. McNaughton, Canada, flour and potato starch. For the excellent quality of samples.

Parson Bros., Toronto, Canada, for an extensive exhibition of the derivatives of petroleum.

E. Billings, of the Geological Survey, Canada, for his published decades on Canadian fossils, and his valuable general contributions to palaeontology.

English and Canadian Mining Co., for the skill and perseverance with which they have opened their ground, and the discovery of composites conformable with the stratification.

Foley & Co., Canada, for plans of mines, ores and lead, smelted in the colony.

J. Steiry Hunt, of the Geological Survey, Canada, for the instructively described series of the crystalline works of Canada, and his various published contributions to geological chemistry.

Larue & Co., Canada, for excellent cast iron railway wheels made from bog iron ore, which have run 150,000 miles.

Montreal Mining Co., for interesting series of copper ores, accompanied by sections of the workings.

A. Taylor, Canada, for good specimens of crude and prepared gypsum, with plans and sections of the gypsum mines.

The officers of the Geological Survey of Canada, for an admirably prepared selection of specimens, illustrating the mineral resources of the Province.

B. Walton, Canada, for the discovery of good roofing slates.

West Canada Mining Co., for specimens and plans, illustrations of well-worked copper mine.

— Williams (Enniskillen), for introducing an important industry, by sinking the artesian wells in the Devonshire strata for petroleum.

New Brunswick Companies, for general collection of the works and minerals of the colony.

The Government of Newfoundland, for a general collection of the rocks and minerals of the Island.

Rev. Mr. Honeyman, Nova Scotia, for a large collection of specimens illustrating the geology of the colony.

Prof. Howe, Nova Scotia, for collection arranged by him, illustrative of the rocks and minerals of the Province.

Government of Nova Scotia, for the large and instructive collection, illustrating the occurrence of gold.

J. Scott, Nova Scotia, for column of coal, showing the entire height of the seam, 34 feet; one of the thickest known beds in the world.

#### HONOURABLY MENTIONED.

The following is a list of those who are honourably mentioned:

E. L. Betts, Canada, J. Hodges, Canada, and Sir S. M. Peto, Bart., M. P., a collective honourable mention for the successful execution of the Victoria Bridge, and for the ingenuity displayed by Mr. Hodges in constructing the coffer dams for the same.

New Brunswick Commissioners, models of bridges. For the utility of the works represented by the models.

Prof. Howe, Nova Scotia, for goodness of quality of specimen building stones.

T. Scarfe, Nova Scotia, good quality of common and pressed brick, and drain tiles

Balmer & Sheppard, Canada, for the excellence of his white bricks and drain tiles.

Missisquoi Drain Tile Company, Canada, for drain tiles of good quality.

F. Claudet for a series of views in New Westminster, British Columbia.

Bowren & Cox, New Brunswick, for photographic views, being the earliest taken in that colony.

W. H. Adams, of New Brunswick, for railway springs.

— Spiller, New Brunswick, for collection of edge tools.

G. Connell, Nova Scotia, for axes.

Mrs. W. Black, for her models of fruits.

Gordon & Keith, Nova Scotia, for the excellent workmanship of their furniture.

James Thomson, Canada, for his collection of birds.

E. O. Richards, Canada, for model of water wheel.

Fleming & Humbert, New Brunswick, for oscillating steam engine.

W. G. Simpson, Nova Scotia, for model of gold washer.

Government of Prince Edwards Island, for good specimens of tanned landskin rugs.

L. D. Sovereign, Canada, for his combined cultivator and drill.

H. Collard, Canada, for his cultivator.

S. H. Gilbert, New Brunswick, for his model of stone picker.

S. Sharp, Canada, Great Western Railway, model of sleeping and freight cars.

A. Bronson, Canada, for magnificent sections of strobis and white oak.

— Burrows, Canada, for fine sections of "landrus sassafras."

Jacob Choate, Canada, for fine cherry wood and soft maple planks.

— Coutlee, Canada, for named collection of 72 woods of the colony.

O. Gingras, Canada, for fine planks of timber.

Miss Crooks, Canada, for collection of 490 native plants.

F. X. Prieux, Canada, for a named collection of 74 woods of the colony.

E. H. Rose, Canada, for a box of very fine walnut veneers.

— Truman, New Brunswick, for veneers of good quality, and a book formed of inlaid slabs, barks, &c., illustrating the woods of the colony.

N. Norman, Newfoundland, preserved curlew, goodness of quality.

Nova Scotia Commissioners, salted salmon, goodness of quality.

Rev. F. L. D'Heureux, maple sugar, illustrative.

The Agricultural Society of Huntingdon, L.C., for barley, grown by Mr. McNaughton.

The Agricultural Society of Wentworth, U. C., for collection of wheat, goodness of quality.

T. Badham, Canada, for oats of good quality.

J. Logan, Canada for barley, goodness of quality.

A. Shaw, Canada, for Indian corn and marrowfat peas, excellent quality.

C. Wilkins, Canada, Indian corn, goodness of quality.

Miss Bossoult, Nova Scotia, for water colour paintings of native flowers, as instructive.

Dr. Howe, Nova Scotia, medicinal and other plants.

W. H. A. Davis, Canada, for interesting and instructive specimens from a remarkable deposit.

H. T. McCaw, Canada, for fine instructive specimens of ores running with the stratification, and illustrating the structure of the country.

S. Sweet & Co., Canada, for fine and instructive specimens of ores, running with the stratification, and illustrating the structure of the country.

#### Cultivation of Winter Wheat.

From a prize essay in the *American Agriculturist*, on this topic, we select the following paragraphs:

Wheat, one of the greatest staples of the country, if rightly managed, may be made one of the most profitable of our cereals, upon almost any soil. Twenty years' experience has demonstrated to me that we hardly need fail of success, if the following mode of proceeding be strictly followed.

**Selection of Seed.**—Select none but the best seed of bearded wheat. The white chaff is preferable, it being worth some ten cents more per bushel in Eastern markets. Prepare a strong brine—do not depend on old beef or pork brine,—and wash as long as any filth or immature grain rises to the surface. By this process we shall expel from two to three quarts of foul seed and shrunken grain per bushel, from what would be called an "extra" article. Seed prepared in this manner will send up none but the

most hardy and vigorous plants, consequently will be less liable to winter-kill; and as like produces like, we may look for an article in the increase equal if not superior to that which was sown. Add three quarts of dry, fresh-slaked lime to every bushel of wheat; mix up thoroughly two days or two weeks, previous to sowing. *This is important—neglect the lime,* and nine cases out of ten you will have more or less smut, which will depreciate the value of the wheat.

*Preparation of Ground, Seeding, &c.*—The ground, if rich and strong enough, may be sown after peas, otherwise after summer fallow. In either case, manure on the surface, and plow or drag in with the wheat. I prefer to use about fifteen loads to the acre thus prepared; then, after sowing thinly, to plow it in. The seed, by coming in immediate contact with the manure, receives a thrifty and vigorous start, which it otherwise would not attain. This I think is highly important to insure success. I have never used the drill, but in its stead Ide's cultivator, which answers a good purpose. If you harrow in the seed, in no case roll afterwards, as the inequalities of the surface will prevent the snow from blowing off, and the plants will be less liable to be affected by frost. But if covered with a drill or cultivator, this precaution is unnecessary, the seed being so much deeper, and the roots less exposed. When the ground is settled in spring, go over with a heavy roller; it covers many exposed roots and often adds five to seven bushels per acre.

Have the ground well pulverized for sowing; it is useless to sow on lumpy and badly prepared soil. In case there is no manure to be had, cover the surface immediately after sowing and before the wheat starts, with a layer of straw; the wheat in a short time will come through, and prevent it from blowing off. The straw will act as a mulch, and the ground being shaded will retain the moisture; and if the soil is not very poor, you may expect a good paying crop. Two and-a-half bushels salt per acre tends to prevent rust, makes the straw strong and bright, and gives the young wheat a dark color. If any one doubts the truth of this statement, I hope he will make the experiment, and my word for it, he will at once adopt the practice. I know of no better mode to prevent the ravages of the midge than early sowing, and even this sometimes fails. The last week in August, or the first in September, I would prefer but this depends upon circumstances; if the weather is dry and not, I would rather wait until October.—Some years since I made an experiment to test early and late sowing. One piece was sowed the last week in August; one the last week in September, and one the middle of October, on the same kind of soil and treated in every respect alike. There was no difference in the time of ripening or in the quality of the grain, but the

earliest sowed produced the longest heads, consequently yielded more per acre.

I do not sow plaster on wheat, as it tends to rust, and increases the bulk of straw but not of grain.

### A Two-story Milking Stool.

"Something new under the sun," in the shape of a milking stool for kicking and unruly cows, is described by a correspondent of the *Iowa Homestead*. The stool can be made of inch boards, and has many advantages over the old-fashioned one. First procure a piece of board of sufficient size to accomodate the milker, and have, in addition room for the milk pail. This may be put on legs of about eight inches in height. Then upon this erect another seat or stool, covering half the space of the bottom one, for the milker to sit, thereby giving him a chance in front to let the pail remain firm and steady, not liable to get kicked over, and by being up from the ground kept free from dirt and mud, and so close to the udder as to prevent loss from milking over, &c. If a cow is in the habit of kicking, the milker, by using a stool of this description, can have both hands to prevent her heels from coming in contact with the pail, which sits firm upon the front part of the stool, steadied by his knees. He could in a short time effectually break a cow of the habit of kicking while being milked.

## Horticultural.

### Toronto Horticultural Society.

#### SECOND EXHIBITION OF THE SEASON.

The second Exhibition this season of the Toronto Horticultural Society was held yesterday in the Gardens, and was attended by a very large number of visitors. In the afternoon the band of the 30th regiment was present and played a number of select airs. The flowers, fruit, &c., were shown in the large pavilion, which in the evening was brightly illuminated, and presented a very pleasing and attractive scene, crowded as it was with the youth and beauty of the city. In some particulars the exhibition was superior to many which have previously been held by the Society, and in others a great improvement was apparent. There was a magnificent display of foliage and green-house plants, which possessed beauties for every taste and were really the first of their kind. In this department Hon. Judge Harrison was an extensive exhibitor. In one collection of twelve plants from his conservatory, there were some very fine specimens—among them the *Raphis flabelliformis*, not before shown in Toronto, and

the *Crotoria Augustifolia*, a plant whose foliage is very rich and beautiful. These specimens were very generally admired. From the greenhouse of the Hon. Justice Morrison another and equally as fine a collection of plants was exhibited. Chief in this group was the majestic *Cyanophylla magnifica*, with splendidly coloured leaves upwards of two feet in length and fifteen inches broad. The plant exceeded four feet in height. The ladies, who are generally excellent judges, were warm in their admiration of this superb specimen. A new and rare collection of foliage plants from the conservatory of D. L. Macpherson, Esq., was also shown. It embraced some choice and well-grown *Begonias*; a specimen of the *Mammoptoris Nidus*, a rare plant with long, slender, smooth leaves, full hued and rich; and a little *Argyrea tricolor*, the delicate colouring of whose foliage attracted much observation. Of stove-plants Judge Harrison was a principal contributor. Of his collection two were particularly worthy of notice, as being well grown and richly flowered—*Oncidium flexuosum* and *Cattleya Mossiae*. An excellent collection was also exhibited by Mr. C. Young, gardener to the Hon. Justice Morrison, among which was a very pretty plant bearing a yellow flower called *cassia corambosa*. The foliage of this specimen was as choice as the flower was beautiful. In a separate collection of Judge Harrison's, which, by the way, carried off the first prize, were a fine *clero deudron fallax* and another, *Erythrina cristigalli*, both of which excited much comment and admiration. A third collection from the conservatory of the same gentlemen contained several superb specimens of *Gloxinia*, which secured for him the first. They had evidently been carefully nurtured and attended, and deserved the admiration bestowed upon them by visitors.—There was a good display of *fuchsias*, a plant everywhere a favorite because of the graceful rise of its stem and the brilliant and varied colours of its flowers. The choicest lot was shown by Mr. C. Young, the fruit of whose taste and skill was certainly much to be admired. Several specimens of *Calceolaria* were displayed, but they were hardly equal to those shown at former exhibitions. On the whole, the show of hot-house plants was capital, and reflected much credit upon the taste of the gentlemen by whom they were entered for competition.

Of cut flowers the display, although choice and beautiful, was limited. Mr. John Gray, of the "Lakeview" nursery, who has always something very elegant wherewith to gratify visitors to these exhibitions, displayed a superb collection of hybrid perpetual roses, most of them being new importations the first time exhibited in Toronto. Conspicuous in it was *General Jacqueminotte*, a flower which

has carried off innumerable "first prizes" at horticultural shows in England, and which went a great way towards securing Mr. Gray the first prize yesterday, which was so justly awarded him. The *Duchess de Cambacerus* and *Jules Margottin* were other varieties of roses to be seen in the collection, both being superb specimens of the "queen of flowers." Judge Harrison was the exhibitor of another collection of roses, well grown but not equal in point of beauty to those of Mr. Gray. A third, and by no means inferior lot, was from the gardens of Mr. George Leslie, one of the oldest and most experienced nurserymen of this city. An assortment of fine hardy garden roses was shown by Mr. J. Forsyth, of the Normal school; and Judge Harrison displayed some very fine roses of the Bourbon variety—among them the *Isabella Gray*, an American variety of singular beauty. No great improvement on former exhibitions was manifested in verbenas, the chief exhibitor of which was Mr. C. Young. The season is rather early for dahlias, but notwithstanding some very good specimens of this favorite flower were displayed. They were grown by Judge Harrison. The same gentleman and noted horticulturist exhibited some pretty specimens of pinks. The only carnations we noticed were grown by Mr. C. Young. They were well developed and delicately colored. The same gardener exhibited a collection of picotees, and a choice collection it was. Mr. George Leslie showed some phloxes, which, considering the season, were very good. There were some achimenes and balsams on view; and Mr. J. Bain displayed a very good collection of stocks, for which he was awarded a prize. Of table and hand bouquets seven altogether were shown. We missed from the collection the tasteful handiwork of Professor Hirschfelder, who has contributed many handsome collections to the exhibitions of the Society. Some well arranged bouquets were shown, however, by the Rev. E. Baldwin and Mr. J. Brown; and Mr. J. Fleming and Judge Harrison displayed hand bouquets of considerable beauty and merit.

The display of fruits was large and excellent. Cherries, gooseberries, strawberries, currants, raspberries, &c., were shown in great profusion; and most of the varieties were of the largest and best description. Of gooseberries Mr. J. D. Humphreys was a successful exhibitor. The collection for which he gained the first prize was fine beyond comparison—the berries being large, fine flavored, luscious. The chief contributors of cherries were Messrs. George Tattle, J. D. Humphreys, George Leslie, R. Stibbles and J. Grainger. They were all fine descriptions and deserved encomiums heaped upon them. A plate of fine white grapes was shown by Judge Harrison. Although not large they were of fine

flavor and altogether a very superior article. What shall we say of the strawberries, especially of the *Triomphe de Gand* variety, shown by Mr. George Leslie? They were certainly an extraordinary production both as regards size and sweetness. We envy Mr. Leslie the possession of such fruit. The currants and raspberries appeared to possess all the qualities that contribute to excellence. Hon. G. W. Allan, President of the Society, displayed three plates of apples of last year's growth, looking as fresh and plump as if they had just been plucked from the parent stem. Mr. Allen's secret of preserving fruits is a valuable one if the process is always as successful as in this instance. There were four varieties shown—snow apples, which are rarely kept in good condition after December, Pomme-Grise, Spitzbergen and red winter streak. One of the chief attractions of the exhibition was the house orchard trees of Mr. Macpherson, bearing fruit almost ripe and of more than ordinary size. There were pears, peaches and nectarines thickly depending from the branches of small trees not more than five feet in height—all grown in pots under the roof of the green house. It was a truly magnificent display, and did credit to the exhibitor.

The vegetable show was not so extensive as at some previous exhibitions, but everything displayed was of the best description. The lettuce, cabbage, potatoes, rhubarb, cauliflower, &c., were all very good. The principal exhibitors were Messrs. Tattle, J. Grainiger and J. Brown, gardener to Mr. W. H. Boulton.—*Leader, July 17th.*

### Hamilton Horticultural Society's Exhibition.

The second Exhibition of the Hamilton Horticultural Society for this season, was held in the Mechanics Institute, on Friday, 25th inst. By early dawn the gardeners and amateurs, like the birds of the morning were all astir, and might be seen with their various productions carefully wending their way to the Hall, no doubt full of hopes of the coming events.

The hot, and green-houses of W. P. McLaren, R. Juson, John Young, T. C. Kerr, and John Brown, Esqs., contributed largely to the exhibition. The green-house and Stove plants although not so numerous as on the former occasion, were creditable. A collection of Foliage plants from Mr. McLaren was very much admired, particularly a magnificent plant of the *Musa Cavendishii*. This noble plant from its appearance may be expected to flower and fruit next season. In describing a plant of the same species, from the gardens of John Brown, Esq., exhibited at the last May show, when I said in my report of it, that it was called by some the Indian bread tree, this is so far true, but the real

Bread tree it is not. The Bread tree proper, or the plant so called by Linnæus, is the *Artocarpus Incisa*, of the South Sea Islands. I mention this to prevent any misunderstanding.

The prize Fuchsias from John Young and R. Juson, Esqrs., were very good for the time of season, they were much admired, particularly the smallest ones; the taste in growing this fine variety of plants is becoming more refined, the lesser being preferred to the greater. In the collection of Green House plants from Mr. Browns there was a fine plant of *Oncidium Flexuosum*, this beautiful Orchides species is of Brazilian nativity. The Orchidæ are a singular tribe of plants, peculiar in shape and growth, they are famous for their flowers, as well as their odd shapes and unique foliage. Some of their flowers are remarkably strange and curiously shaped. *Oncidium Papilio*, bears a striking resemblance to a butterfly on wing, others to heads and bodies of animals, the tropical varieties are rather difficult to cultivate, particularly those of them which in their nature resemble the parasitical tribe of plants.

The cut flowers were well represented, Stocks, Hollyhocks and Verbenas in abundance. The prize Carnations formed a stand of 12, from the garden of Mr. Wm. Muir, Esq., there were also two seedlings from the same garden which were commended.

The amateurs made a very good show of Cottage window-plants; but not with so many as we would like to have seen. Mrs. Sharp, Dr. Craigie and Mr. Michael were the successful competitors. Mr. Weatherston, an amateur, exhibited some very fine French Marigolds, and double Zinnæas, and carried off the first prizes for the Dahlias and Roses. H. Colbeck, Esq., exhibited a few very fine spikes of *Campanula Medium*, which was very much admired, Mr. T. Racey, nursery man, and Mr. A. Peachy, gardener to E. B. Wood, Esq., Brantford, exhibited collections of Hollyhocks and Antirrhinums, Mr. Mackay from the same place, Petunias, all very worthy of notice.

The Orchard-house trees from the gardens of W. P. McLaren, T. C. Kerr, Esqrs., and Bruce & Murray's nursery, attracted very much attention; they were all in a full bearing state well grown, particularly those from the garden of T. C. Kerr, Esq. The vines from Bruce and Murray's nursery, were of the sweet water variety, two years old; on the one 13, and on the other were 15 clusters of ripe fruit.

Two dishes of Peaches from John Young, Esq., and two dishes of Nectarines from Bruce & Murray's were much admired.

The collection of cherries was large and fine, especially those of Messrs. Freed, Iottredge and Fearman. Gooseberries plentiful, varieties many, those from the gardens of John Young, W. P. McLaren, and John Brown, Esqrs., were the finest we have seen for a long time. Dr. Craigie exhibited Black Greens of the

Scotch kind, they were of a good size and an excellent flavour. Black, red and white Currants and Raspberries were in abundance, a few Strawberries and Tomatoes.

The vegetable department was very full; the potatoes from Messrs. Kelvington, Freed, Taylor and Wildes were excellent; the Peas, better and more fully represented than heretofore. The Rev. Mr. Rice exhibited a pea he calls the String pea, it appears to be a rather a peculiar variety, has very long and broad pods, resembles very much the Kidney bean and may be cooked in the same manner, cabbages, cauliflowers, onions, carrots, turnips, &c. &c., with two very full collections of vegetables from Messrs. Wilds and Kelvington, the whole very creditable to the market gardeners and other growers.

We had a beautiful day, a very good Show, well patronized in the afternoon and evening by the elite and beauty of the city.

Like draws to like, the ladies for the flowers, and the flowers for the ladies.

GEO. LAING.

Hamilton, July 30th, 1862.

### Fruit Growers' Association of Upper Canada.

PROCEEDINGS OF MEETING HELD IN THE TOWN HALL, ST. CATHARINES ON WEDNESDAY, JULY THE 16TH 1862.

#### *Editor of the Canadian Agriculturist.*

SIR—The meeting of the Fruit Growers' Association, called for 16th inst., was organized at 2 p.m., Judge Logie in the chair. The minutes of the two previous meetings were read and approved, after which the meeting went into discussion of the Fruits on Exhibition. Of cherries there was a very fine collection—some 20 varieties.

Mr. W. H. Read, of Port Dalhousie, had a fine sample of cherries, among which was a new variety of great promise, large size, the Monstrous DeMezel. Also, a fine sample of Raspberries.

Mr. Freed, of Hamilton, showed 16 varieties of cherries, of the leading kinds. A really fine collection.

Messrs. Bruce & Murray, of Hamilton, exhibited a superb collection of Gooseberries, 17 varieties, many of them unusually large.

Mr. Meston, of Hamilton, also showed a very fine collection of Gooseberries, some 15 varieties, and two varieties of Plums, one of them was Rivers' early Prolific, a new and excellent Plum.

Mr. Philip Gregory, of Louth, had a fine collection of Cherries, 8 varieties. Among them were some of the best in cultivation—also 3 varieties of large currants, very fine.

Geo. Dean, gardener to Mr. James Taylor, St. Catharines, showed 5 varieties of Gooseberries, very fine, 3 varieties of large currants,

also 5 varieties of Raspberries. The above Fruits showed the effects of good cultivation.

Mr. R. N. Ball, Niagara, exhibited three varieties of cherries, and the yellow cap Raspberry, all very fine.

Dr. Watts, of Niagara, showed a fine bunch of red grape currants—a bunch of white smooth Gooseberries. Also 4 varieties of cherries, very fine.

S. Shaw, of St. Catharines, showed two plates of exceedingly fine gooseberries.

Mr. M. Y. Keating, of Louth, showed a fine sample of red cherry and white grape currants, also Napoleon B gameau cherries.

Mr. Sherlock, of Louth, showed a very fine sample of the black heart cherry.

Mr. T. H. Grydon, of St. Catharines, exhibited a sample of Downer's late red cherry first season of bearing—seem prolific. Also Lanning's new white strawberry, very large and fine flavor. Duc de Malakoff, very large and fine; also British Queen. A ripe tomato, in open air obtained by plunging a pot in the ground. Mr. Graydon has had Duc de Malakoff strawberry to measure 7 inches in circumference the present season.

J. Outhbert, gardener of Thomas Merritt, Esq., St. Catharines, showed 12 varieties of Gooseberries, very large.

A seedling apple from the garden of Sir A. McNab, Hamilton, of last years growth, was exhibited in a fine state of preservation.

Rev. Mr. Dixon, of Port Dalhousie, exhibited a fine sample of Triumph de Gand strawberry; also a variety of white strawberries from Lower Canada, of the Alpine Family.

Mr. D. W. Beadle, St. Catharines, exhibited 11 varieties of cherries, among which was a new seedling, pronounced by the meeting to be an unusually delicious cherry, and if it should prove hardy and prolific, will be one of the very best in cultivation.

Wm. McGiverin, Esq., of St. Catharines, exhibited a very choice collection of plants and flowers, comprising 6 varieties Begonias, 6 varieties of Caladiums, 25 varieties of Anteorhinums and Verbenas. Also 5 varieties of Gooseberries, 3 of currants, 2 of Raspberries, and a plate of black heart cherries.

R. Miller, Esq., placed on the table three plates of cherries; some most noble samples of the Napoleon Bigarreau, unsurpassed by any others exhibited.

Mr. John Tackle, of the Montebello Gardens, sent a beautiful specimen of the Carosinea Speciosa in flower.

Mr. John Holder placed on the stand seven varieties of Begonia, and several other beautiful foliage plants. A fine specimen of that most exquisitely scented Gerdinia Fortunei, in flower, and quite a collection of other showy and beautiful things, among which we noticed particularly Oldenlandia Depii, Streptocarpus Rex, Musa

Caendishii, Calandum Madriana, and that curious Acrosichium Aleicorne, besides some lovely Orchids in full bloom.

At the close of the discussion, the Secretary laid before the meeting a large amount of information, obtaining an answer to the questions of the Association. As the matter was too extensive for consideration at this meeting, a committee was formed, composed of Messrs. D. W. Beadle, James A. Campbell, of Grantham, and P. Gregory, of Louth, to make out a condensed report for the Winter Meeting. The President then read a letter from the Royal Horticultural Society of England, relating to the International Exhibition of Fruits to be held 8th of October, 1862. On motion of Dr. Craigie, seconded by Mr. Murray, it was resolved that the Secretary acknowledge the letter received from the Royal Horticultural Society, and state that on account of the early day named for the Exhibition, it will not be possible for us to send a sufficient number of specimens that are fully colored and matured, to give a good representation of Canadian Fruits.

A vote of thanks was then moved by Dr. Craigie, seconded by Mr. W. Holton, to the Mayor and Council of the Town of St. Catharines, for their kindness and liberality in granting the free use of the Town Hall, for the meeting of the Association.

The meeting then proceeded to the discussion appointed for this session, as follows, taking up the varieties, seriatim.

In order that all persons desirous of sending samples of Canadian Fruit to the International Exhibition of the Royal Horticultural Society may have an opportunity of doing so. I send you a copy of the Secretary's letter to Dr. Hurlburt, and the Prize List.

The accompanying letter from Mr. John Freed, of Hamilton, in relation to the cultivation of the cherry, was received by the Secretary and laid before the Association, also the letter from Mr. Wilson, of Ontario.

The meeting was one of unusual interest.—The discussions were lively and the attendance large, about forty members being present. The members adjourned at 10 p. m. to meet again in Toronto, on the 12th of November next, much gratified with the fine display of fruit and flowers and the information elicited.

D. W. BEADLE,  
Secretary.

St. Catharines, July 30, 1862.

#### DISCUSSION ON FRUITS.

**Black Tartarian.**—Dr. Craigie, of Hamilton. Is one of the finest varieties in cultivation. —Mr. Laing, of Hamilton. It is very prolific, and hardy of its class.

Mr. Murray, of Hamilton. Is one of the best, hardy and prolific.

Mr. Meston, of Hamilton. Is a universal favourite, prolific and hardy of its class.

Mr. Freed, of Hamilton. The best black cherry.

Mr. W. H. Read, of Port Dalhousie. My favourite, the best black cherry, tree hardy.

Jas. A. Campbell, of Grantham. The best and largest cherry.

Mr. P. Gregory, of Louth. A good cherry, and ornamental tree, have some others equally good.

Mr. W. H. Smith, of Grimsby. The best black cherry, hardy.

Mr. S. Taylor, of Pelham. A good bearer, and hardy tree, of first quality.

Rev. Mr. Dixon, of Port Dalhousie. The tree does admirably, recommend for general cultivation south of Lake Ontario and Great Western Railway.

**Elkhorn or—**Rev. Mr. Dixon, of Port Dalhousie. Is an excellent late variety, had never failed with me for ten years, is hardy, have trees 18 to 20 years old.

Mr. R. N. Boll, of Niagara. Is hardy.

Mr. W. M. Smith, of Grimsby. Is perfectly hardy, valuable as a late cherry.

Mr. P. Gregory, of Louth. Has always borne until last year, when I had none of any kind, best late variety.

Mr. W. H. Read, of Port Dalhousie. Is large and fine with me.

Mr. S. Taylor, or Pelham. Is very hardy, and a good bearer. Valuable in its season.

Recommended for general cultivation South of Lake Ontario and G.W. Railway, as an excellent late variety.

**Black Eagle**—Mr. R. N. Ball, of Niagara. Is a fine cherry, hardy and prolific.

Mr. W. M. Smith, of Grimsby. Is next to the black Tartarian, hardy.

Mr. James A. Campbell, of Grantham. The tree is more hardy than the black Tartarian.

Mr. W. H. Read, of Port Dalhousie. Not a great bearer, but quality excellent.

M. Freed, of Hamilton. With me the tree is very productive, and hardy.

Mr. Meston, of Hamilton. An excellent cherry, rather a poor bearer.

Mr. Murray, of Hamilton. Is a fine fruit.

Mr. Laing, of Hamilton, an excellent fruit, but an indifferent bearer.

Mr. T. Taylor, of Pelham. Sweetest cherry I grow, a good bearer.

Mr. Pawling, of Louth. It is my opinion that the above varieties of cherries succeed best in a dry gravelly or sandy soil, do not do well on clay.

Mr. James A. Campbell, of Grantham. Trees grow rapidly on highly manured soil, are apt to burst the bark; received for general cultivation South of Lake Ontario and G. W. Railway.

**Knight's Early Black.**—Mr. P. Gregory, of Louth. I have a tree 17 years old, a good cherry, and prolific.

Mr. W. H. Read, of Port Dalhousie. Had a tree, but it cracked and died.

Mr. Meston, of Hamilton. Is a tree of slow growth, hardy, rather a poor bearer, quality good.

Recommended for further trial.

*American Heart*—Mr. Freed, of Hamilton. Pipers with black Tartarian, quality very good, if not the best; not very prolific, hardy so far as known.

Mr. Murray, of Hamilton. The tree bears young, and is hardy.

Mr. Holton, of Hamilton. Is a very fine cherry, hardy of its class, would recommend it for further trial.

Recommended for further trial.

*Napoleon Bigarreau*.—Rev. Mr. Dixon, of Port Dalhousie. Think it is inferior to Yellow Spanish.

Mr. Jas. A. Campbell, of Grantham. Is more liable to speck and crack than the Yellow Spanish.

Mr. Pawling, of Louth. Is the second to the Yellow Spanish.

Mr. W. M. Smith, of Grimsby. Is very productive, one of the most productive and best market cherries.

Mr. W. H. Read, of Port Dalhousie, very prolific, one of the largest, very fine, and valuable market variety.

Mr. Freed, of Hamilton. A good market cherry, more productive than any other of that class.

Mr. Meston, of Hamilton. Is an exceedingly productive and hardy variety.

Mr. Laing, of Hamilton. A most productive variety.

Mr. Holton, of Hamilton. Can fully corroborate what has been said in favour of this cherry.

Mr. R. N. Ball, of Niagara. Is a great bearer. Recommended for general cultivation, south of Lake Ontario and G. W. Railway.

*Elton*.—Rev. Mr. Dixon, of Port Dalhousie, would recommend it as a very good cherry.

Mr. W. M. Smith of Grimsby. Is a hardy variety, prolific, very good.

Mr. W. H. Read, of Port Dalhousie. Do not value it.

Mr. Meston, of Hamilton. Is prolific and hardy.

Mr. H. Laing, of Hamilton. Is very good and prolific.

Mr. W. Holton, of Hamilton. Is a very valuable cherry for Canada,—one of the most hardy of its class,—will stand but where few of its class will live.

Recommended for general cultivation south of Lake Ontario, and G. W. R. Railway, and for further trial in the more northern parts of the Province.

*American Amber*—Rev. Mr. Dixon, of Port Dalhousie. Is inferior to others of same season.

Mr. Gregory of Louth. Is hardy, medium quality. Not very prolific.

Mr. Read, of Port Dalhousie. With me bears well; good quality, and hardy.

Mr. Freed, of Hamilton. Bears well, medium quality, a good cooker.

Mr. W. H. Holton, of Hamilton. Don't think much of it, is too small.

Mr. R. N. Ball, Niagara. Is a second rate cherry.

Not recommended.

*Early Purple*.—Mr. Freed of Hamilton, about same time as *Bowman's May*.

Rev. Mr. Dixon, of Port Dalhousie. The birds eat all the fruit with me.

Mr. W. M. Smith, of Grimsby, a good early variety. Birds eat all the fruit.

Mr. W. H. Read, of Port Dalhousie. Prefers it to *Bowman's May*.

Mr. S. Taylor of Pelham. Thrives well with me; bears well, a good early sort.

Recommended for general cultivation South of Lake Ontario and G. W. Railway.

*Bigarreau du Mai*.—Birds eat it, is valuable as an early variety.

Mr. W. H. Read, of Port Dalhousie. Is a bird cherry, nothing but skin and bone, not equal to the early purple.

Mr. Freed, of Hamilton. A great bearer.

Mr. W. Holton of Hmailton. Is only valuable as an early variety.

Not Recommended.

*Black Cherry Seedling*—From Sir. A. McNab.

Mr. Laing, of Hamilton. Is a good bearer.

Mr. Jas. A. Campbell, of Grantham. Is a cherry of fine quality.

Mr. Pawling, of Louth. A good cherry, but there are better of the same season.

*Bigarreau*—or Yellow Spanish.—Mr. Jas. Campbell, of Grantham. A hardy cherry of its class.

Mr. Pawling, of Louth. One of the most valuable, hardy, and good bearers.

Mr. W. H. Read, of Port Dalhousie. Is hardy, vigorous, an abundant bearer, flesh firm.

Mr. Freed, of Hamilton. Not very productive with me, but a fine cherry.

Mr. Laing, of Hamilton. Is one of the best cherries.

Mr. W. Holton, of Hamilton. An old Standard sort,—Stands at the head of its class, fine for preserving, and a good market variety. Recommended for general cultivation South of Lake Ontario and G. W. Railway.

*Monstreuse de Meziel*.—Mr. W. H. Read, of Port Dalhousie. Is a very vigorous grower, leaf large. Tree ornamental, is hardy, have a tree six years old, bears well, quality very good.

Mr. Freed, of Hamilton. A very fine cherry of the *Bigarreau* class.

Recommended for further trial.

*May Duke*.—Mr. P. Gregory, of Louth. Bears well, but have been unsuccessful in growing the tree, a good cooking cherry.

Mr. Jas. Campbell, of Grantham. Is the

only cherry I have known to succeed North side of Lake Ontario, is in bearing at Wellington Square, good for cooking, good for market, a valuable variety.

Mr. Laing, of Hamilton. A very good cherry, one of the first of its class, not troubled with the curculio.

Mr. W. H. Read, of Port Dalhousie. A fine cherry, good for cooking, and family use.

Mr. R. N. Ball, Niagara. Very valuable, particularly for its hardness.

Mr. Graydon, of St. Catharines. A first rate cherry.

Mr. W. Holton, of Hamilton. One of the finest for general cultivation. Tree hardy, a good cooking, a valuable variety.

Mr. Freed, of Hamilton. One of the most valuable grown for Canada, ripens its fruit gradually, excellent for cooking and preserving.

Rev. Mr. Dixon, of Port Dalhousie. A valuable variety.

Recommended for general cultivation.

*Late Duke.*—Mr. Holton, of Hamilton. A fine cherry in its season, very hardy.

Mr. Freed, of Hamilton. Is a firm cherry, not as vigorous as the May Duke, hardy.

Recommended for further trial.

*Jeffries Duke.*—Mr. Freed, of Hamilton. Is equally valuable with the May Duke, ripens its fruit a little later, a good bearer, and as hardy as the May Duke.

*Queen Hortense.*—Mr. Holton, of Hamilton. The tree is as hardy as the May Duke.

Mr. Jas. A. Campbell, of Grantham. Tree appears to be hardy.

Mr. D. W. Beadle, of St. Catharines, shewed a fine sample of the fruit.

*Governor Wood.*—Mr. Graydon, of St. Catharines. A splendid cherry, in my opinion the best cherry, a good bearer.

Mr. R. N. Ball, of Niagara. A very fine variety.

Mr. Gregory, of Louth. Promises well, sweet and fine.

Mr. Freed, of Hamilton. The tree grows well, is prolific, the best early cherry, ripens near the same time as the Bigreau, or *du Mai*.

Mr. W. H. Read, of Port Dalhousie. Is well adapted for general cultivation, quality the best, a good bearer.

Mr. Laing, of Hamilton. Is one of the best, a good bearer.

Mr. Jas. A. Campbell, of Grantham. A very productive cherry, of medium size, and good quality.

Mr. Holton, of Hamilton. A good cherry, valuable where it will succeed, one of the best of the Heart class.

Rev. Mr. Dixon, of Port Dalhousie. A very excellent variety, a good bearer, and vigorous.

Mr. Murray, of Hamilton. One of the best, if not the very best, a fine bearer, hardy.

Recommended for general cultivation South of Lake Ontario, and G. W. Railway.

*Belle d'Orleans.*—Mr. W. H. Read, of Port Dalhousie. The best early cherry, large red cheeked, sugary tender pulp, and prolific.

*Transparent Guigne.*—Rev. Mr. Dixon, of Port Dalhousie. Is sweet, very prolific, and hardy, comes in after the Black Tartarian.

Mr. Freed, of Hamilton. Don't think it worth recommending,—is small, late, is not eaten by the birds.

Mr. P. Gregory, of Louth. Value it as a dessert cherry, hangs on the tree well, is good to dry, I prefer it to some others. Not a good market cherry, yet would not like to dispense with it.

*Marvel de September.*—Exhibited by Mr. Freed, of Hamilton, quite green, it is of the Duke class.

*Red Bigreau.*—Shewn by Mr. Freed, of Hamilton. Is hardy, very fine flesh, not as good as others of same class.

*Belle de Choisy.*—Rev. Mr. Dixon, of Port Dalhousie. Does not bear with Mr. D. W. Beadle, nor with me, and this was the general testimony.

*Dover's Late.*—Shewn by Mr. Graydon, of St. Catharines.—First year of bearing it seems prolific.

*Cleavland Bigreau.*—Shewn by Mr. Freed, of Hamilton. Is very productive, a showey grower,—probably tender.

#### GOOSEBERRY.

*Whitesmith.*—Mr. Murray, of Hamilton. One of the best English varieties, least liable to mildew, a fine grower. Should be in every collection.

Mr. Minhinnick, of W. Square. About the best, does well on clay loam, I prune early in the spring, and put on a good coat of well rotted manure each Spring.

Mr. Laing, of Hamilton. I keep them in a moist atmosphere, and moist, not wet soil, I pinch in the stools. Is one of the best varieties.

Mr. W. H. Read, of Port Dalhousie. Is a large firm berry, does not mildew when grown near water. Sulphur is a sure remedy if applied.

Mr. Freed, of Hamilton. Does well, is free from mildew.

Mr. Meston, of Hamilton. An excellent berry, a sure bearer,—not the largest, mildews occasionally, have tried sulphur after the mildew had set in, but it only took the leaves off. High cultivation is a good preventive of Mildew.

Mr. Pawling, of Louth. Without special cultivation sometimes mildews. On a dry clay soil, with south aspect, very subject to mildew. Plaster of Paris is a good preventative.

Mr. Gregory, of Louth. Even native varieties mildew with me.

Mr. Thos. Shaw, of St. Catharines, exhibited a fine sample of Whitesmith Gooseberry, grown on dry gravelly soil, free from mildew.

Recommended for general cultivation.

**Warrington Red.**—Mr. Meston, of Hamilton. Is the best Red Gooseberry, an excellent bearer, not the largest, sometimes mildews, has a weeping habit, and very thorny.

Mr. Murray, of Hamilton. The best Red Gooseberry, a very fine bearer, not free from mildew, a showey grower, and weeping habit. Recommended for general cultivation.

**Crown Bob.**—Mr. Murray, of Hamilton. A first rate variety, very large, full bearer, a little subject to being scalded, not free from mildew.

Mr. Jas. A. Campbell, of Grantham. I have near all the English varieties, and they are most of them moulded.

Mr. Minhinnick, of Wellington Square. Is not as good as the Whitesmith, but very good, is not subject to mildew with me.

Mr. Freed, of Hamilton. Mildews worse than the Whitesmith with me.

Recommended for general cultivation.

**Sulphur Yellow.**—Mr. Murray, of Hamilton. Is one of the best early yellow varieties, a very vigorous grower.

Recommended for general cultivation.

**Houghton Seedling.**—Recommended by the meeting as not being subject to mildew.

**Heart of Oak.**—Recommended by Messrs. Meston, Laing, and Murray, of Hamilton as a very large and excellent variety.

Ontario, Wentworth County, }  
15th July, 1862. }

*Letter from Mr. Wilson.*

To the Chairman of the "Fruit Growers Association,"

SIR,—As I cannot have the pleasure of attending your meeting, at the last moment I have snatched a little time to pen a few remarks upon Horticulture, which may contribute perhaps some useful information. As to the culture of the Gooseberry we have always been successful for many years, and never were plagued with the mildew; our garden is heavy rich clay loam; the kind we raise is the large oblong, green English variety, a sample of which I enclose for the Society to name. I believe that no one will be troubled with mildew if they would haul good clay loam into their gardens, if the location is sandy; the same remarks will apply to the grape vine. The clay soil should be manured from time time, and kept mellow with proper cultivation. They may be propagated by cuttings; new varieties are raised from seed. The cuttings should be taken from the strongest and straightest shoots of the last season's growth, and about 12 inches long. If trained as standards cut out all the buds except three or four

at the upper end, to prevent the appearance of troublesome suckers around the main stem. Experience has shown, however, that the bushes will be longer lived, and much more productive, when permitted to sucker \* moderately, than if the whole support of the top be drawn through a single channel.

By a judicious system of pruning, the bearing wood will be frequently renewed, and the sap will be wasted upon that which has become old and barren.

The cuttings should be inserted about half their length in a bed of rich moist soil, situated on the north side of a fence, or in some shaded spot. In the second year after they are well rooted they may be transplanted to their permanent places, and from 3 to 4 feet apart, or the cuttings I generally plant at once where they are intended to grow. Being exceedingly sensitive to the heat and drouth, they require a soil at once deep and moist. A liberal application of manure should be mixed in the soil at the outset, and also each year when the ground is dug; frequent hoeings through the summer are essential to good cultivation.

HOW TO PLANT FRUIT TREES.

In the Spring of 1851, I purchased 50 apple and peach trees from Dr. Beadle, the peach branches were much winter killed, and I was obliged to cut them short; my ground was, part of it, much worn out and drowned out, the other part was 20 years old, just broken up, there was also a severe drought that season. Under all these disadvantages I planted my trees. The old orchard having been sold off during wild cat times for an enormous sum, I had to plant again and could not wait to prepare the ground.

I lost none out of the 50 the first year, though the growth was slow owing to the drouth, and they did not make much wood to stand the winter, so that this year three of my peach trees died. I got 70 or 80 more trees of various kinds this season, and planted in the same manner and they are all growing notwithstanding the repeated frosts and the long and early drought of 1862. After this I shall think my plan much better than mulching. *Modus Operandi.*—First stake out the ground with a tape, then dig good large holes on the North side of the stake, then haul with a team a good wheelbarrow load of old chaff manure that has been well turned and rotted, put two shovelfuls in the bottom, then a good shovelful of sandy loam, have the roots of the trees dipped well in thick mud, set the tree, then put on sufficient sandy loam to cover the roots, and jar the tree so that the fine soil will descend well amongst the roots, fill up with

\* Several members desired to express their entire dissent from this mode of allowing any suckers.

plenty of manure \* then a light covering of soil. This way of planting immediately enriches the soil, and at the same time keeps it moist. Frequent use of the plough, cultivator and hoe is necessary to good success. Wishing your society every success.

I am gentlemen, yours very respectfully,

FRANCIS G. WILLSON.

*Letter From Mr. Freed.*

Hamilton, July 16, 1862.

D. W. BEADLE, Esq.,

*Sec. of Fruit Growers' Association of U. C.*

DEAR SIR,—The cherry being one of the subjects for discussion to day, I beg to hand you the following note on the native Plum Stock, *Prunis Americana* of Botanists, as an excellent one upon which to bud the cherry; particularly for growing the cherry in pots for orchard-house culture, for Dwarfs, Pyramids, Wall and Trellis training, and for clay or moist soils where the cherry fails.

For Pot culture, I have not the least doubt but that it will supersede the Mahaleb or any other stock, furnishing by root pruning abundance of medium, even sized roots; a most important desideratum in pot culture.

With respect to root pruning the same remark will apply to Dwarfs, Pyramids, Wall or Trellis training. And on clay or moist soils where the Mazzard and Mahaleb stocks have failed, I have not the least doubt but when worked on this plan the trees will succeed to the entire satisfaction of the planter.

In addition to the stock bearing root pruning so well, it is also most remarkable for producing early and prolific blossom buds, fruiting the second year from the bud, and producing fruit of the highest excellence. In fact the Plum stock seems to produce the same effect on the cherry as the Quince does on the Pear.

I have a few trees only. They are now in their fifth year of growth, look very healthy and bore good crops of fine fruit.

These are some of the good qualities I claim for the Wild Plum as a stock for the cherry, and the original introduction to the public.

Yours truly,

JOHN FREED.

*Letter from Secretary of Royal Horticultural Society.*

ROYAL HORTICULTURAL SOCIETY, }  
South Kensington, W., June 14th, 1862. }

SIR,—I am directed by the Council of the Royal Horticultural Society to express to you the pleasure with which they would receive contributions of fruit from the different Societies in

Canada, to their great Exhibition of fruit to be held here on the 8th of October.

I enclose a dozen programmes of the schedules, and beg your kind assistance in obtaining through your Canadian Societies a worthy representation of the fruit cultivated in that country.

I have the honour to be, Sir,

Your most obedient servant,

ANDREW MURRAY.

PRIZE LIST FOR THE GREAT INTERNATIONAL SHOW OF FRUIT, GOURDS, ROOTS, VEGETABLES, AND CEREALS, AT THE ROYAL HORTICULTURAL SOCIETY'S GARDENS, SOUTH KENSINGTON, LONDON, ENGLAND. OPEN TO ALL THE WORLD. WEDNESDAY, THURSDAY, & FRIDAY, OCTOBER 8th 9th & 10th. GOURDS, ROOTS, AND CEREALS WILL REMAIN ON EXHIBITION UNTIL OCT. 18th.

*Special Regulations.*

I. Exhibitors must give at least five clear days' notice, *in writing*, to the Superintendent, of the subjects they intend to exhibit, and the area in square feet of table-room required, and all roots must be sent washed and ready for exhibition. No application will be attended to after FRIDAY, THE 3rd OF OCTOBER.

II. All specimens of Roots must be delivered at the Gardens not later than Monday, the 6th of October, and, if sent, the carriage must be prepaid.

III. No Fruit or Garden Vegetables will be admitted after 8-30 on the morning of October 8th, and all arrangements must be completed before 10 a. m.

IV. Cards corresponding with the entries will be furnished to Exhibitors on the morning of the Exhibition at the entrance to the Gardens; and the Exhibitors will be responsible for the proper placing of these cards.

V. All Fruits and Vegetables must have been grown by the Exhibitor, or they will not be eligible to compete for the Prizes, except in Class A and Gourds and Cereals. All subjects exhibited must be correctly named. No Exhibitor can take more than one Prize in the same class.

VI. Tickets of admission will be furnished to the Exhibitors as follows:—

For 12 Subjects and upwards exhibited, 2 passes.  
For 3 Subjects and upwards exhibited, 1 pass.  
No Exhibitor can take more than 6 passes.

VII. The Exhibition of Fruits and perishable Vegetables will close on Friday, the 10th, and of Gourds and other vegetables, on the 18th of October, at 5 p. m., after which all specimens will be given up to their owners.

\* There is need of some caution in using even well rotted manure in planting trees lest they be killed by a surfeit.  
Note by the Sec. F. G. Arso.

## LIST OF PRIZES.

NOTE.—A dish of Apples, Pears, Oranges, Lemons, and the like, 6 fruits of each; but of Plums, 9 fruits.

| FRUITS.                                                                                           |  | 1st Prize | 2nd Prize | 3rd Prize |        |

| X. Apples, kitchen, single dish.....                                                              |  | 1 0       | 0 15      | 0 10      | 2 5    |
| Y. Apples, kitchen. Heaviest 5.                                                                   |  | 1 0       | 0 15      | 0 10      | 2 5    |
| NOTE.—Fruits specified in the above Classes will be excluded from GG.                             |  |           |           |           |        |
| GG. Miscellaneous.....                                                                            |  | 2 0       | 1 10      | 1 0       | 4 10   |
|                                                                                                   |  |           |           |           | £165 0 |

## Care of Trees in Orchards

There seems to be a diversity of opinions as to whether orchards should or should not be cultivated with other crops. If trees appear weak and unthrifty in growth, the soil should be manured and cultivated until they assume a healthy and free growing appearance. After that, the orchard should be seeded down to grass, not neglecting thereafter, as of the first importance, an annual top-dressing or mulching under each tree.

The borer—keep him out of your orchard by all means! It can be done we think, and among the plans recommended, none seem more judicious than that given by a correspondent of the *Gardener's Monthly*. He has effectually prevented the ravages of this destructive pest by removing the earth from the stem of the tree, so that the bark will harden down on the collar. It is well known that this insect never penetrates at any other point than where the bark, form its contact with the soil, becomes tender. This is doubtless correct, and if so, similar methods could be almost as easily tried, and would per-

haps be more effectual. Among these, putting a bandage round the trees, for two inches below and six above the surface of the ground, is a good one. The bandage can be made of coarse muslin; put on once a year for three or four years, and the operation could be performed with considerable dispatch. Another mode is to cover the trunks of trees at the roots, and for five or six inches upwards with a coating of grafting wax, afterwards putting on the linen bandage if deemed necessary. The cost of thus protecting an orchard of fifty or a hundred trees would be a mere trifle as considered in regard to the benefit to be derived therefrom. It should not be forgotten that any of these plans only keep the borer from the trees after they are applied—they do not destroy those already in the tree; hence the knife and wire must be used in clearing them from their holes previous to putting on the bandages.

Our orchardists sustain a great loss by not giving proper attention to their trees. An annual outlay of five dollars, bestowed upon a small orchard of young trees, in the way of mulching, protection from the borer, &c., will in as many years, bring it into a more productive and better condition than twenty years' time, if allowed to take care of itself.

## Mignonette as a Tree.

Buy a pot of ordinary mignonette. This pot will probably contain a tuft composed of many plants produced from seeds. Pull up all but one; and, as the mignonette is one of the most rustic of plants, which may be treated without any delicacy, the single plant that is left in the middle of the pot, may be rigorously trimmed, leaving only one shoot. This shoot you must attach to a slender stick, of white osier. The extremity of this shoot will put forth a bunch of flower-buds, that must be cut off entirely, leaving not a single bud. The stalk, in consequence of this treatment, will put out a multitude of young shoots, that must be allowed to develop freely until they are about three inches and a half long. Then select out of these, four, six, or eight, according to the strength of the plant, with equal spaces between them. Now, with a slender rod of white osier, or better, with a piece of whale-bone, make a hoop, and attach your shoots to it, supported at the proper height. When they have grown two or three inches longer, and are going to bloom, support them by a second hoop, like the first. Let them bloom, but take off the seed pods before new shoots will appear, just below the places where the flowers were. From among these new shoots, choose the one on each branch, which is in the best situation to replace what you have nipped off. Little by little, the principal stalk, and also the branches, will be-

come woody, and your mignonette will no longer be an herbaceous plant, except at its upper extremities, which will bloom all the year, without interruption. It will be truly a tree-mignonette, living for an indefinite period—for with proper treatment, a tree-mignonette will live twelve to fifteen years.—*Parlor Gardener.*

### The Black Knot.

The knots are now making their appearance on the plum and cherry trees, and require attention. Those who will make a careful examination of the excrescence will be able to find some marks upon them, sometimes crescent shaped, like the curculio mark upon the fruit. By a very careful dissection a minute white speck may be found in the middle of the concave portion of this crescent.—This is an egg of an insect. It is believed that the egg causes this excrescence, and we suppose so, because we know that this egg becomes a grub, and burrows in and feeds upon the substance of this knot. These grubs, if raised to maturity become beetles, so like the curculio that stings the fruit, as not to be distinguished from each other. Still they may be different. There are many different kinds of beetles that look much alike. The pea-bug and the beetle from the worm in the chestnut, both look much like the curculio, but differ greatly in their habits.

When we cut into one of the little balls found growing upon an oak leaf, and find there a full grown perfect fly, and no possible way it could have got there from without, we suppose that the parent of that fly, in some way or other, caused that ball to grow, and that it grew to afford protection and food for her young. This is a natural supposition, and is probably true, although it would be hard to prove. Acting upon such a theory as regards the black knot, we should say cut them off as soon as they appear, and you destroy the embryo insect that would cause similar knots another year.

We have seen both plum and cherry trees about this city, and indeed almost wherever we travel, perfectly deformed with these excrescences, and permitted to stand year after year, mere nurseries for spreading this evil.

Many people carefully cut off these knots early in the spring, and it is well enough to do so even then, as it certainly removes a deformity, but it then avails nothing towards getting rid of the cause.

By careful watching and prompt cutting away during the early part of July, you may keep the enemy under your control, but by neglecting them for a year or two, valuable trees, or even orchards, will become worthless.—*Newark Mercury.*

## Botanical.

### Notes on the Coniferous Plants of Japan.

BY JOHN C. VETCH.

There is probably no country in the world of the same area which produces so great a variety of conifers as the group of islands composing the empire of Japan. From Nagasaki in the south to Hakodadi in the north, conifers are everywhere abundant, and in great variety. Travellers have hitherto been enabled to explore but an exceedingly small portion of these islands, and it seems more than probable that the numerous mountain ridges of the interior produce a great number of entirely new and as yet undiscovered species.

The Japanese are great admirers of all evergreens, and much trouble is taken to cultivate them. The greater portion of the timber used for building and for all ordinary purposes is that of coniferous trees. The annual demand is enormous throughout all parts of the empire, and it is said that landowners are compelled to plant a certain number of forest trees yearly, in order to replenish the stock of the country. Conifers are employed very largely for garden decoration. Clipped hedges of the *Cryptomeria*, *Retinosporas*, *Biotas*, &c., are very general, and scarcely a garden can be met with that does not contain specimens trained and cut into grotesque forms. The main roads which intersect this country are very generally planted on either side with rows of conifers. *Pinus densiflora* and *Massoniana*, *Cryptomeria japonica*, and *Thujaopsis dolabrata* are the most common kinds employed for this purpose. Trees thus planted are very seldom cut down, and consequently they attain a great size, and form specimens of the utmost beauty.

Altogether conifers form the most useful and the most generally employed trees in Japan. Most of the kinds which have been discovered by travellers have now been introduced to European gardens, and there being every prospect of the greater portion proving sufficiently hardy to withstand our severest winters, it is confidently hoped that ere long many of the beautiful species which are at present found in Japan only will be distributed throughout our pleasure-grounds, and flourish as luxuriantly as they do in that country. Subjoined is a list of the principal species which have come under my notice, either in a wild state or cultivated in gardens. The Japanese names for the several species are given as far as can be correctly ascertained.

*Abies Alcockiana*: *Toraonomi*—A noble tree, discovered in September, 1860, during Mr. Alcock's trip to the sacred mountain of Fusi-yama, and named in honour of that gentleman. It grows from 90 to 100 feet in height, at an elevation of 6,000 to 7,000 feet. The timber is

good, and numbers of trees are being constantly felled and sold in the neighboring towns.

*Abies firma: momi*.—One of the finest species found in Japan, and one which will, doubtless, prove hardy in Europe. It is a handsome and remarkably straight growing tree, found at an elevation of 3 000 to 4 000 feet. It grows from 80 to 100 feet in height.

*Abies Itsuga: Itsuga*.—Found growing on Mount Fujiyama at an elevation of 6 500 feet. It grows from 80 to 100 feet in height, and its timber is highly valued by the Japanese.

*Abies Jezoensis: Jesso-Matsu*.—A tree growing some 60 feet in height on the island of Jesso.

*Abies leptolepis: Fusi Matsu*.—Found at an elevation of 8 000 to 8 500 feet on Mount Fusi-yama. It is nearly allied to the common larch, but differs from it in being a more slender tree, and having slightly different cones. It is remarkable as being the tree which grows at the greatest elevation on Mount Fusi-yama. Its greatest height is 40 feet, but on reaching an elevation of 8 500 feet it becomes a stunted bush of  $1\frac{1}{2}$  to 2 feet.

*Abies Microsperma*.—A species hitherto found only in the vicinity of Hakodadi, on the island of Jesso. Very little is known about this tree, as two specimens only were seen, which were some 20 to 30 feet in height. It promises, however, to be one of the handsomest of its genus.

*Abies Veitchii*.—A species found at an elevation of 6 000 to 7 000 feet on Mount Fusi-yama. It forms a beautiful tree from 120 to 150 feet in height, with small and very glaucous cones. The Japanese say that the species is peculiar to this mountain.

*Abies bifida: Saga-nomi*.—A variety distinguished from others growing in this country, by its leaves being divided at the point into two sharp points. It does not grow wild in the districts to which Europeans have access, but is largely cultivated in gardens. The trunk of this tree is remarkably straight, attaining a height of 80 to 100 feet. As a timber tree it is invaluable to the Japanese.

*Cunninghamia sinensis: Liu kin momi*.—Not seen in a wild state, but is commonly planted in gardens, where it forms a graceful tree with drooping branches, from 20 to 25 feet in height. —*Gardeners' Chronicle.*

From the Country Gentleman and Cultivator.

### Pleuro Pneumonia Epizootica.

MESSRS. EDITORS:—Having observed in several of your latest numbers of the *Country Gentleman*, some statements and enquiries respecting the above disease, which appears to be

still *latent* in the United States, I have much pleasure in submitting the following account of the disease to your readers.

Pleuro-pneumonia in cattle, occurring in the epizootic form, although only known in the United States within the last two or three years,\* is now and has been very prevalent in the old world for many years back. In Scotland, and more particularly amongst the dairy stock of its large towns, it has raged with a threatening virulence and fatality scarcely to be credited, except by those daily coming in contact with it. I may as well state at the commencement, that the following remarks and opinions have been gathered and formed, from practice among the dairy cows in the city of Edinboro', to which class of stock they must chiefly apply, although I would not suppose that there would be any marked difference from the disease, as it appears amongst dairy and stock cattle in the rural districts.

Pleuro pneumonia may be defined to be a specific inflammatory affection of the lungs and serous membranes within the thoracic cavity.—There are many other definitions varying only from each other in several points of minor importance, but to me, the above one which I have given, has always seemed to answer and meet our present knowledge of the disease—more so, when we consider how much of it is still involved in doubt and obscurity.

*Symptoms.*—This disease cannot at all times in its earlier stage, be recognized from other affections of the lungs of an inflammatory character, for even its own first appearances are not always marked by the same symptoms, more particularly the type of the accompanying fever. It has been divided into three distinct stages:

- 1st. The incubative stage.
- 2d. The active inflammatory stage.
- 3d. The hectic or exhaustive.

This partitioning off of the disease is a matter which must be clearly understood, for while I have no doubt but that the two latter stages are characterized by a distinct set of symptoms, during the progress of the disease, I at the same time have never been able, and am of opinion that we cannot detect the exact time when the one stage ends and the other commences. They seem to run into each other without producing any distinct line of demarkation, the symptoms of each often being mixed up in the same case at one and the same time. As for the first or incubative stage, which signifies the period of time elapsing betwixt the first contraction of the disease and its development into the second stage, it is my opinion that it can scarcely ever be recognized—(of course when the active symptoms appear, we may be sure that this stage has

\* We think there is no doubt but that occasional instances of Pleuro-pneumonia occurred in this country some years previous to the date mentioned by our correspondent, several of which have been fully described in former volumes of this paper.—EDS. CO. GENT.

preceded them.) We may from many circumstances have our suspicions aroused, that some one or more among a lot is affected, but as far as I am aware there are no sure symptoms which would enable us to come to a direct conclusion. I know at least that this is the case among the dairy stock in Edinboro'; even their constant attendants rarely remark anything unusual about them, until the disease is considerably advanced, and I have even in some instances, although happily they are rare, known one animal to be in the last stages, before anything like serious attention was paid to her case, so apt are their owners to attribute diminution of the appetite and milk to something trivial.

Amongst the very earliest of the symptoms, there is a disposition to restlessness, the cow moving from off one fore foot and resting her weight on the other alternately, and the urine diminished in quantity and much higher in color with a strong disagreeable odor; in unfavourable cases this condition of the urine remains all through the disease. If on this appearance of the urine, some of it be collected and tested by some competent person, and there be found to be an almost or total absence of the chlorides in it, we would be warranted in suspecting that some inflammatory disease of the lungs existed; our attention would at least be drawn to those organs requiring a careful examination. The urine is generally observed to be unusual like, just a few days before the animal begins to shy her food. They lose their appetite generally gradually at first; if they leave off feeding all at once, which they sometimes do, it is an unfavourable symptom, such cases generally running their course rapidly and fatally, and more especially if the same is observed of the *milk*. The udder at an early stage of this disease is very hot, the teats unusually so, and painful. There is a falling off of the yield of milk, but as I have said above, if it is suddenly suspended we have reason to apprehend the worst. Many cows continue to give milk all through the disease, even although they are not eating much, which is a favourable symptom, indicating a good constitution, and a tendency to an early return to health. The animal now appears dull and listless—back slightly arched and head poked out; the hind legs are brought forward beneath the abdomen. Many attach importance to the animals flinching on being pressed along the spine. This, however, is never a symptom of disease amongst dairy cows, as almost any cow in health will do so. The withers are cold; irregular heat of the extremities and ears, the former usually inclined to be cold; the eyes are unusually bright and injected; there is a knuckling of the hind fetlocks frequently observed in the earliest stages, indicating inflammation of the pericardium and pleural membranes within the chest; rumination is suspended; the forelegs are posed, with the toes inwards and elbows outwards, to assist respiration by affording increased chest room. The

respiration is short and hurried, averaging at first from 30 to 40 acts per minute; pulse at first hard and quick, averaging 76. Both the respiration and pulse, however, quickly change; the former become heavy and oppressed, and accompanied with a characteristic grunt at each expiration; this sound is also produced by pressing the cow over the intercostal spaces, and it indicates the adhesion of the pleural to the inside of the ribs. The pulse, at first hard and quick, changes to a quick weak pulse, with which change we generally have emaciation—the nostrils are expanded with a muco-purulent discharge issuing from them. Cough is generally present, but it is not always a symptom. At first it is dry and husky—latterly becoming short, hacking, and painful. The dung at first is inclined to be dry and hard, and deficient in quantity; as the disease advances it also changes, and we have diarrhoea present; this at an early stage of the complaint in young cows, and when other symptoms are favourable, is said to be a good symptom; but where it comes on later, from the presence of fermented food in the stomach and the impoverished poisoned state of the blood, it is a very bad symptom.

These, the usual prominent and most important symptoms of pleuro-pneumonia, now gradually become more aggravated as debility sets in. This is well marked in the staggering crouching gait, the extreme emaciation, occasional shivering, and weak tremulous pulse. There is now in most cases gaseous distension of the first stomach, and an apparent bulging out of the thoracic walls, the belly tucked up, skin yellowish and adhering closely to the ribs; the surface of the body is cold, she grinds her teeth, and there is a discharge of saliva from the mouth. Along with a distension of the stomach, we have frequent eructations of gas up the oesophagus. This is often present in the early stages, and is a good diagnostic symptom.

Unlike the horse, cows afflicted with this disease will lie down; but this is accounted for by the difference in the anatomy of the parts—the broad flat sternum and a peculiarity on the lower articulation of the ribs, admitting readily of lateral expansion of the chest. If one side is affected, she will lie upon it or towards it, so as to free the other for respiratory purposes; and if both are affected, she will either stand or lie upon the sternum, and occasionally on each side alternately. Auscultation is in this disease a valuable aid in enabling us to form a correct diagnosis, but it can only be practiced by those conversant with the healthy and unhealthy sounds of the chest, or by the scientific Veterinarian—although I know many men, who from long and dearly bought experience, can at once tell an animal afflicted with this disease, merely from the symptoms I have given, and without at all studying the condition of the lungs.

The duration of the pleuro-pneumonia differs much in different cases, according to the age,

breed and constitution of the animal and the state of health immediately preceding its contraction. Young cattle stand the disease well, that is from two to five years old; younger and above that again they have not the same capabilities of resisting it. Cows of a medium size and weight, and well proportioned bone and muscle, such as the Ayrshire, stand well, while on the other hand I have generally observed that poor, ill-conditioned cross-breeds, and large heavy-bodied cattle sink rapidly. The incubative stage is said to extend to the sixth week; at least those who believe in its contagious or infectious character, do not consider their cattle safe until that time has expired; indeed they often show symptoms before that time, counting from the period when they were known to be in the vicinity of diseased stock, often just about the sixth week, but rarely after it, unless from some other cause not recognizable. The active febrile stage rarely lasts over eight days, as the lungs become early hepatized, typhoid fever sets in, and debility, followed by collapse and death varying from a fortnight to a month from the time the cow is first observed ill. Those cases which last out through all the stages generally begin to recover tone and appetite in about two months, and some not as late as till the tenth or eleventh week.

The duration and comparative fatality of the disease is also influenced to a great extent by the amount and situation of the lung tissue involved; thus if both lungs are attacked at once, the case is very bad. At other times, one lung is affected near the centre of it; this also is bad, but not so much so as the other. Sometimes it attacks the lower edges of the lungs, and proceeds upwards and forwards. Such cases often get better, even although the whole lung be utterly useless for respiratory purposes, provided the opposite lung does not become involved, and I have known many cases get better where even both lungs were affected from the first, their lower and posterior edges being chiefly implicated. After much observation I have come to the conclusion that the danger is increased materially as the disease nears and involves the centre and anterior portions of the lungs, and more especially if the investing membrane of the heart become implicated. Also the lung on the right side is the one which is most frequently attacked.

In my next I will follow up this subject, treating of its nature, post mortem appearance and treatment, &c.

R. RUTHERFORD, V.S.

*Late of St. John, N. B*

Edinburgh, Scotland, June, 1862.

### What Horses we Need.

The Agricultural Editor of the Cincinnati *Gazette* is furnishing that paper with a series of articles upon the horse. In regard to the kind

of horses needed in the United States, he says:

The United States is pre eminent for its trotters. But there is no breed of trotters except the Morgans, and the many names which have signalized the trotting courses belong to the common stock of the country. They are accidental trotters, and their qualities developed by superior training. The moral sentiment of the people is so hostile to the gambling of the race course, that running became unpopular. The carriage and buggy having taken the place of riding on horseback, trotting was a useful gait, and trotting races have been tolerated on account of it. Hence our sports of the turf are shown in these, and the training skill of sportsmen directed on trotting horses. We need skilful breeders to establish a trotting stock. It is true that the Morgans have much to claim our admiration. For general usefulness they have no superiors. Their fast gaits, medium size, endurance and excellent disposition, point them out as the best for family purposes. But still, the more showy carriage horse, such as Consternation, Messenger, Hamiltonian, Highlanders, etc., will often command a more ready sale, and the breeding of these should command greater attention than they do. Our fault is too much mixing and it is too habitually setting at defiance the adaptation of the points of the mare and stallion to each other. This evil is facilitated by the numerous classes of horses that are here. Our importations embrace every valuable kind for every valuable purpose, and their numerous crosses on the common stock have given a diversity of forms and blood that make breeding for especial purposes, such as for the carriage and buggy, no easy matter. The forms and blood of stallions generally have so little to do with each other, that a Highlander begets a Diomedé colt, and a Morgan shows an undersized offspring without the qualities which are characteristic of the breed. Even good diverse qualities neutralize each other, and the progeny exhibits either none of the qualities of the parents, or so much modified as to be of little value.

For farming purposes, heavy horses are not needed. A fast walk in the plow is the most useful gait, for experiments show that the draft of the plow is not increased by speed; hence it may be run at the same depth at three miles an hour, as at two miles, without any additional strength from the horse. A horse therefore, that will walk three miles an hour in the plow is worth a third more than one that walks but two.

A farmer, too, wants a horse that will trot his buggy eight miles an hour; and fast walking and trotting, with endurance, easy keep and kind disposition, are the qualities that all want. A slow, poking plow horse is not desirable for any purpose, save when the farmer is in new ground with the plow, and oxen are better there. Our general breeding should look to the higher qualities—to fast gaits, gentle disposition, nervous energy and *intelligence*; for there is as great dif-

ference in the minds of horses as in the human race.

The two-horse Yankee wagon has superseded the four-horse wagon, because a quick trip to town, with thirty bushels of wheat drawn by two horses, is much better than a slow one of fifty bushels with four horses; and speed, now-a-days is desirable, even of a Sunday, when the wagon conveys the family to church. This is a fast age in all things, and the slow, poking, dull, stupid horse is wanted nowhere.

That Government will need many more horses than it has in past times, is pretty certain. For cavalry, the good qualities I have particularized, are demanded. Whether to reconnoitre or to cover a retreat, or to pursue a retreating enemy, or surprise guerilla parties—for all the purposes of war, a heavy cavalry horse is not wanted. Greater strength is needed for the artillery service, but even here speed, too, is demanded, and the large showy fast trotting horse of the carriage, is more desirable than the slower draft stock.

Even in the dray a good walk is important, although weight of body is absolutely necessary to resist by its momentum the jarring arising from the uneven surface of city payments.

### Choice of Animals for Fattening.

Mr. Hedley contributes the following valuable hints on fattening cattle to the Newcastle Club, and which we find published in the *Agricultural Gazette*, England. He says:

"In my close identification with fat cattle for several years, I have always found that the best animals have the most massive heads, most capacious chests, and the strongest spines. I have, therefore, evolved a few rules to go by in the purchase of lean ones, and scarcely with one exception I have found them to be applicable. The head of any of our bovine races ought to have the first consideration; this is the true index to the vital acumen, and even bodily construction, and will be found to foreshadow all good or bad that may be accomplished. Thus an animal possessed of a broad, full, spacious skull, with strong evenly-bent, defective horns, will be found to have a thick neck at the base, wide thorax, and strong, nervous system; while one with long, narrow, contracted skull, and puny, abruptly-bent horns, will be characterized by weakness, wildness, and slowness to fatten. A small, dull, sunken eye betokens hardness of touch and inaptitude to fatten; and a bright, large, open, eye, *vice versa*. A staring, dark, fiery eye often accompanies a small forehead and hereditary wildness, and when combined with small, drooping horns, and a chin with no loose skin hanging from it, is a very depicable animal indeed, weak in constitution, predisposed to lung disease, and sterile in fattening propensities.—Animals with weakly formed heads have always small loins, and the width of these parts will

always be found in an exact ratio with the strength of the head. The nose, instead of being long and fine, as Virgil, Aristotle, and several other naturalists recommend it, ought in my opinion, to be thick, strong, and near the ear as possible, if only in proportion to the size of the frame. Thickness of nose and thickness of chest are often twins, and so are thin, meager, irregular noses and consumption. Small, snipy noses oft sniff the air into frames of small capacities, and are joined to mouths that can crop but very small morsels at a time. These observations I have found to be applicable to any of the kinds of cattle shown at Newcastle market. But besides the shapes of animals, the age and class must always have especial consideration, and be adapted according to food and situation; otherwise, the realization of remunerative profit will be uncertain."

### Miscellaneous.

**IMPORTANCE OF SLEEP.**—One most effectual method of promoting the health of children is to allow them a sufficiency of "Nature's sweet restorer, balmy sleep." Till they are six or seven years old, they daily require from ten to twelve hours' sleep, particularly if they have ample outdoor exercise; as they grow older, the quantity may be gradually diminished. Children ought to rise early, say by six in Summer and by seven or half past seven in Winter; consequently, they ought to go to bed, when young, by six or seven o'clock; when they require less sleep, they may sit up longer with safety; but there are few habits more injurious to children than sitting up to a late hour. If children sleep soundly, they are generally awake at the proper time in good humour, and will often rouse their parents from slumber by their cheerful prattle or simple song. To secure sound sleep for them, it is necessary that their beds be not too soft; a hair or chaff mattress being certainly the best. The head should be so far raised by the bolster as to be on a line with the spine, so as to preserve a free circulation in the blood-vessels going to and from the head. They should not be over-loaded with clothing; but during the first three or four winters of their lives they need the warmth which can only be obtained by sleeping in blankets, especially if they sleep alone; and in most cases this is very desirable. Till a child is able to get out of bed himself, he should sleep in a room with some one whose watchfulness can be depended upon. Children should always be not only permitted, but encouraged, to rise as soon as they awake; indeed, when they are old enough to rise without help, they should, if needful, be stimulated by reward to get up immediately on awaking. Such a habit, formed in childhood, and persevered in through life, may avert much physical and moral injury. To this end care should be taken that every needful comfort be

provided for them by the time they rise; if they have not to wait to be dressed, or to shiver for want of fire, and if they be not restricted in their play for fear of rousing the adults of the family, they will not wish to lie in bed when they have had sufficient sleep. There is not a more delightful sound to a mother's ears than the joyous laughter of her little ones in the early morning; it speaks of health and happiness, and of that freedom from care which only childhood can enjoy. If children be fretful in a morning we may be sure either that they are poorly, or that their wants are not properly attended to. By making the morning hours pleasant, you render the habit of early-rising easy of acquisition; and when we consider the effect which such a habit will have on the physical, intellectual, and moral powers of our children through life, we cannot too strenuously exert ourselves in assisting them to establish it. The impressions first made on the mind in the morning generally continue through the day, and give a colour to every event which occurs. It is therefore of great importance that children should be spoken to with kindness and cheerfulness when they first awake; and if mothers cannot themselves attend to them, they ought to impress on the minds of nurses how much trouble they may save themselves, and how much happiness they may impart to their young charge, by getting them into a cheerful happy temper as soon as they arise.—*Mother's Practical Guide.*

**THE PERMANENCE OF SPECIES**—The mind shrinks from contemplating the confusion which must ensue, if the ideas which some entertain as to "transmutations" between species, either in the vegetable or animal world, had any foundation in reality.

In that most instructive series of articles which the learned AGASSIZ is now contributing to the *Atlantic Monthly*, we have not known whether to admire more the clearness and simplicity of his language, or the interest with which he has thus far been enabled to surround subjects of a quite recondite nature. He began with the lowest types of animal life, and has now reached the Polyp Coral—the tiny builder of so many reefs and islands which now support the exuberant vegetation of the tropics and withstand all the power of the waves.

Of these Coral Polyps it appears that there are no less than five species. As to the length of time during which they have been at work we make the following extract, referring to the coral reefs on the Florida Coast:—

Estimating the growth of the Coral Reef according to these and other data of the same character, it should be about half a foot in a century; and a careful comparison which I have made of the condition of the Reef as recorded in an English survey made about a century ago with its present state would justify this conclusion. But allowing a wide margin for inaccuracy

of observation or for any circumstances that might accelerate the growth, and leaving out of consideration the decay of the soft parts and the comminution of the brittle ones, which would subtract so largely from the actual rate of growth, let us double this estimate and call the average increase a foot for every century. In so doing, we are no doubt greatly overrating the rapidity of the progress, and our calculation of the period that must have elapsed in the formation of the Reef will be far within the truth.

The outer Reef, still incomplete, as I have stated, and therefore of course somewhat lower than the inner one, measures about seventy feet in height. Allowing a foot growth for every century, not less than seven thousand years must have elapsed since this Reef began to grow. Some miles nearer the main-land are the Keys, or the inner Reef; and though this must have been longer in the process of formation than the outer one, since its growth is completed, and nearly the whole extent of its surface is transformed into islands, with here and there a narrow break separating them, yet in order to keep fully within the evidence of facts, I will allow only seven thousand years for the formation of this Reef also, making fourteen thousand for the two.

This brings us to the shore-bluffs, consisting simply of another Reef exactly like those already described, except that the lapse of time has united it to the main-land by the complete filling up and consolidation of the channel which once divided it from the extremity of the peninsula, as a channel now separates the Keys from the shore-bluffs, and the outer Reef, again, from the Keys. These three concentric Reefs, then, the outer Reef, the Keys, and the shore-bluffs, if we measure the growth of the two latter on the same low estimate by which I have calculated the rate of progress of the former, cannot have reached their present condition in less than twenty thousand years. Their growth must have been successive, since, as we have seen, all Corals need the fresh action of the open sea upon them, and if either of the outer Reefs had begun to grow before the completion of the inner one, it would have effectually checked the growth of the latter. The absence of an incipient Reef outside of the outer Reef, shows these conclusions to be well founded. The islands capping these three do not exceed in height the level to which the fragments accumulated upon their summits may have been thrown by the heaviest storms. The highest hills of this part of Florida are not over ten or twelve above the level of the sea, and yet the luxuriant vegetation with which they are covered gives them an imposing appearance.

But this is not the end of the story. Travel ling inland from the shore-bluffs, we cross a low flat expanse of land, the Indian hunting ground, which brings us to a row of elevations called

the hummocks. This hunting ground or Everglade as it is so called, is an old channel, changed first to mud-flats and then to dry land by the same kind of accumulation that is filling up the present channels, and the row of hummocks is but an old Coral Reef with the Keys or islands of past days upon its summit. Seven such Reefs and channels of former times have already been traced between the shore-bluffs and Lake Okeechobee, adding some fifty thousand years to our previous estimate. Indeed, upon the lowest calculation, based upon the facts thus far ascertained as to their growth, we cannot suppose that less than seventy thousand years have elapsed since the Coral Reefs already known to exist in Florida began to grow. When we remember that this is but a small portion of the peninsula, and that, though we have not yet any accurate information as to the nature of its interior, yet the facts already ascertained in the northern part of this State, formed like its Southern extremity of Coral growth, justify the inference that the whole of the peninsula is formed of successive concentric Reefs, we must believe that hundreds of thousands of years have elapsed since its formation began. Leaving aside, however, all that part of its history which is not susceptible of positive demonstration in the present state of our knowledge, I will limit my results to the evidence of facts already within our possession; and these give us as the lowest possible estimate a period of seventy thousand years for the formation of that part of the peninsula which extends south of Lake Okeechobee to the present outer Reef.

Here we have an unequalled opportunity of judging as to the Permanence of Species. Shall we find that in these insignificant forms of life, there is any evidence of change, disorder or transmutation? Shall we find any symptoms of "progressive development," or "selection,"—any proof that the laws which separate, "each after its kind," every seed that renews and multiplies the successive generations of the living, are not just as binding at this day as ever before—were not just as binding "in the beginning," as they are now? Let Agassiz answer:

So much for the duration of the Reefs themselves. What, now, do they tell us of the permanence of the Species by which they are formed? In these seventy thousand years has there been any change in the Corals living in the Gulf of Mexico? I answer most emphatically, No. *Astræans*, *Porites*, *Mæandrinæ*, and *Madrepores* were represented by exactly the same Species seventy thousand years ago as they are now. Were we to classify the Florida Corals from the Reefs of the interior, the result would correspond exactly to a classification founded upon the living Corals of the outer Reef to-day: \* \* \* Every Species, in short, that lives upon the present Reef is found in the more ancient ones. They all belong to our geological period, and we cannot, upon the evidence before

us, estimate its duration at less than seventy thousand years, during which no evidence of any change in Species, but on the contrary the strongest proof of the absolute permanence of those Species whose past history we have been able to trace.—*Country Gentleman*.

**SAGACITY OF A DOG.**—A short time ago a dog, well known to the railway officials from his frequent travelling with his master, 'presented himself' at one of the stations on the Fleetwood, Preston, and Longridge line. After looking round for some length of time amongst the passengers and in the carriages, just as the train was about to start he leaped into one of the compartments of a carriage, and laid himself down under the seat. Arriving at Longridge, he took another survey of the passengers, and, after waiting until the station had been cleared, he went into the Railway Station Hotel, searched all the places on the ground floor, then went and made a tour of inspection over the adjoining grounds; but being apparently unsuccessful, trotted back to the train, and took his old position just as it moved off. On reaching the station from which he had first started, he again looked around as before, and took his departure. It seems that he now proceeded to the General Railway Station at Preston, and after repeating the looking around performance, placed himself under one of the seats in a train which he had singled out of the many that are constantly popping in and out, and in due time arrived in Liverpool. He now visited a few places where he had been with his master, of whom, as it afterwards appeared, he was in search. Of his adventures in Liverpool little is known; but he remained all night, and visited Preston again early next morning. Still not finding his missing master, he for the fourth time "took the train"—this time, however, to Lancaster and Carlisle, at which latter place the sagacity and faithfulness of the animal, as well as the perseverance and tact he displayed in prosecuting his search, were rewarded by finding his master.—*Recollections of a Sportsman*. ### The Provincial Exhibition.

---

We beg leave to direct the attention of our readers to the advertisement which appears in another place as to the days for making the entries of articles in the various classes for the approaching Provincial Exhibition. Attention to these dates is absolutely necessary. We have every reason to anticipate that the Exhibition this autumn will be one of the most, if

not altogether the most successful which has yet taken place, and we trust that each one of our readers will do his utmost towards realizing that expectation. The grounds have been enlarged, and the buildings put up for the accommodation of the cattle and horses are ample and substantial. There has unfortunately been a mistake made in the placing of some of them, they being too low in reference to the level of the surrounding ground, but this will be remedied as far as possible before the exhibition takes place. For such portions of the Exhibition as are not provided with permanent buildings temporary structures of a sufficiently substantial character will be put up, and altogether the accommodations will be more extensive and complete than on any former occasion.

### The Board of Agriculture.

The Office of the Board of Agriculture has now been removed to its permanent location in the new Agricultural Hall, corner of Yonge and Queen Streets, Toronto, where all business of the Board and of the association will henceforth be transacted, except during the week of the Exhibition. During the exhibition week the business offices will, of course, be at the Show Grounds.

### THE PROVINCIAL EXHIBITION

OF THE

#### AGRICULTURAL ASSOCIATION OF UPPER CANADA,

**W**ILL be held at the City of Toronto on the 23rd, 24th, 25th, and 26th September next.

Persons intending to exhibit will please take notice that the entries of articles in the respective classes must be made on or before the undermentioned dates:—

Horses, Cattle, Sheep, Swine, Poultry, on or before Saturday, August 16th.

Grain, Field Roots, and other Farm Products, Agricultural Implements, Machinery, Manufactures generally, Saturday, August 30th.

Horticultural Products, Ladies' Work, the Fine Arts, &c., Saturday, September 13th.

Prize Lists and Blank Forms for making the entries upon may be had of the Secretaries of all Agricultural Societies and Mechanics' Institutes throughout the Province.

HUGH C. THOMSON,

*Secretary Board of Agriculture.*

Toronto, August 1, 1862.

### THOROUGH-BRED STOCK FOR SALE.

**T**HE Subscriber has for sale DURHAM and GALLOWAY CATTLE, LEICESTER, COTSWOLD, and LINCOLNSHIRE SHEEP, Male and Female. 10 Durham and Galloway Bull Calves—price from \$100 to \$200; 20 Shearling Rams, weighing from 230 to 285 lbs. each—Price from \$5, to \$100 each.

JOHN SNELL,  
*Edmonton P.O., C. W.*

Four miles from Brampton Station G.T.R.

### EAST RIDING YORK

#### Agricultural Society Fall Show,

**A**T WELLINGTON HOTEL GROUNDS, MARKHAM VILLAGE, 9th October, 1862.

All Entries to be made by the evening of the 8th, or to be peremptorily excluded.

A. BARKER,  
*Secretary.*

### THOROUGH BRED STOCK FOR SALE.

**T**HE SUBSCRIBER has for Sale Durham and Galloway Cattle, male and female.

Leicester, Cotswold, Lincolnshire, Down and Cheviot Sheep; Cumberland and Yorkshire improved Pigs. All imported stock.

GEORGE MILLER.

Markham, June 3rd, 1862.

6t.

### TO BE SOLD BY AUCTION,

*On Thursday, Oct. 16, 1862,*

**T**HE well-known Herd of NORTH DEVON CATTLE, consisting of more than forty head of Cows, Bulls, and Heifers; one hundred and seventy West and Southdown Ewes and Rams; pure blooded Essex Pigs, in pairs fit for breeding.

Catalogues of description, with pedigrees, may be had fourteen days before the sale, on application at the office of the *Galt Reporter*, if by letter, prepaid. Credit of 12 months may be had on approved endorsed paper.

### THE SPLENDID FARM,

Consisting of upwards of THREE HUNDRED ACRES, to be sold by private bargain, on accommodative terms.

DANIEL TYE.

County Waterloo, Wilmot, August 1862. td

### FOR SALE.

**A** LOT of thorough bred improved Berkshire Pigs of various ages.

R. L. DENISON,

Dover Court.

VIEWS OF FARMING IN THE NORTH OF ENGLAND  
AND SCOTLAND, &c.

LONDON, England, July 11, 1862.

EDITORS OF THE CANADIAN AGRICULTURIST.—  
This day's proceedings included the winding up of the duties of the Jurors in a ceremony of a somewhat imposing nature, as you will see by the papers in which the proceedings are reported. I had a position in the procession as one of the Jurors. The whole occupied about three hours, and was pronounced by many to be quite as imposing as the opening ceremony. As far as variety of costume and splendid music were concerned it was quite a success, especially as the day was fine, quite an exception to the general rule in that respect. Since I have been in England there have been very few days that it has not rained less or more. My duties now being at an end here, I leave to-morrow for Sheffield.

12th. Passing by railroad from London to Sheffield, I took a different route from that I travelled in 1851, and passed through a very fine Agricultural country. The crops, particularly of wheat, looked only middling, the spring crops better, and the extensive fields of root crops are very interesting, the turnips in some cases being ready for thinning and in others just coming up. The mangels and potatoes look well, but I did not see an acre of Belgian carrots. They appear not to be cultivated here. Arrived at Sheffield, I remained until Monday morning, and left by an early train for York, where we remained for some time in order to view the Cathedral, which in my humble opinion is the grandest I have seen in England. I had not seen it before, but I think it even finer than St. Pauls. Sheffield has grown very much since I last saw it; the population has increased 50,000 in ten

years and it is a prettily situated place, lying in the storm of a basin, and extending up the finely sloping banks in every direction. For an inland place it is not easy to find a more beautiful place than Sheffield when not obscured by smoke of the furnaces. It is a very busy place, and makes an excellent display of its industrial products at the great exhibition. The varieties of articles in their collection are numerous, and many of them are of rich character, as well as useful. The country for two thirds of the way from Sheffield to York presented a very pleasing aspect, beautifully diversified with hill and dale, until coming near York, when it has rather a flat appearance. On leaving for Berwick on Tweed the same remark applies for some distance, when it again assumes the beautiful undulating surface that is pleasing to the eye, especially when the slopes are covered with luxuriant crops of grain, and well cultivated turnip fields.

Arrived at Berwick we found we were too late for the train that stopped at Ayton, and had to stay until Tuesday morning, when we took the early train for Ayton station, and after breakfast were driven a distance of four miles to Mr. Heriot's (related to Dr. Small, of Toronto.) This is an exceedingly delightful drive over a very fertile tract of land, lying in sight of the sea coast. At Mr. Heriot's we were most hospitably entertained, and had a most interesting ramble about the fields, the crops upon which, including wheat, are as fine as I ever saw. The Messrs. Heriot, father and son, are well entitled to rank amongst first-rate farmers. They are cultivating about 900 acres, besides a range of 600 acres of sheep pasture or moor land at some little distance, which I did not see. They had a good many sheep upon the pasture field on the farm under cultivation. They have very little land from which they take hay on this farm; their horses are fed on oat straw and grain. They have no such thing as naked fallows; the wheat land is prepared by a crop of

beans or turnips. That is the system generally pursued here, and with great advantage, as they are in the habit of sowing winter wheat as late as Christmas, and it then does well. This gives them a long season for feeding off the turnips from the ground before sowing their wheat. Their ploughs are at work nearly all the time. This is one great advantage they have over us in Canada.

On Wednesday we took leave of our kind friends and came to Edinburgh, passing through a tract of finely cultivated country. We arrived in time to go to Holyrood and Calton Hill, the churches, the college, &c., and left in the afternoon for Dunblane, where we staid until Friday morning, when we got into the wrong train and went north for a short distance before discovering our mistake. This caused the loss of a day, as we had to return to Dunblane station, and then take train for Callendar, were too late for the Boat on Lake Katrine, and had to stay at the Trossacks all night. This mistake was not without some compensating advantages, as we had the opportunity while waiting at Dunblane, to see the old Cathedral there, and take a walk round the place, the views about which are delightful, including a fine rapid river. We had also time to climb up the mountain at the Trossacks until we were tired. Saturday morning was very wet, but we went by the first boat up Lake Katrine, and by cars across the hills to Loch Lomond, thence to the head of the Loch, and then down to Glasgow, where we found ourselves one day later than we had intended, and were prevented from getting to our friends at Conaie until Monday. I had written to my worthy friend John Thomson of Mouldy Hill how we were situated, and he met us with his carriage at Gretna, and drove us to his home, a very delightful drive of ten miles. After dinner I went on a tour of inspection over the farm, and the next day our friend drove us up the valley of the Esk to Bonize, past Laugholme, in all a distance of about fourteen miles. This is one of the finest drives in Scotland, and the country is extremely interesting. Several very fine mansions are included in the views. The Holmes, or what we call the Flats, are very fertile, the hills rising to a great height on each side, covered with the finest herbage to the very tops, and dotted over with sheep. These are of the Cheviot breed mostly, though some take a cross from a Leicester Ram when they intend to sell the lambs, as many of the best farmers do, and feed off the ewes, buying fresh ewes every fall. The crops in this part of Scotland, and indeed all over the island of Great Britain, have been very much injured by the extreme wetness of the season. The general opinion is that the wheat crop will be below an average, and in this part the bean crop is very seriously injured, as well as the potatoes, and the turnips have been got in much later than usual. It is said to be the wettest and coldest season they have had for many years. The sportsman will not have their usual shooting, as the young game have been destroyed by the excessive wet and cold.

On Wednesday morning we left for Liverpool via Carisle, passing through some fine tracts of country, and many of the manufacturing towns, in which the chimneys of the manufactories are smokeless, the business being very seriously affected by the scarcity of cotton. The distance to Liverpool, 1.9 miles, was performed in four hours. We arrived here about four o'clock, and embark on board the "Bohemian" to-morrow, bidding good-bye to the shores of glorious Great Britain, Glorious in every sense of the word. May we of Canada long rejoice in the privilege of forming an integral part of the Empire of which she is the head.

Yours, &c,

E. W. THOMSON.

A FEW MAXIMS ABOUT MANURES.—Without manure no good farming is possible. The right way to purchase manures is only by analysis. For practical ignorance cannot be blessed; unless it be pleasant to buy things at double their value, and lose good crops into the bargain. In manuring grass lands "it is the safest and soundest economy to obtain the effect at once, and not by niggardly or piecemeal applications." Manure is the farmers' capital.

### Letter from a Canadian in England.

[We take the liberty of appropriating for our pages the subjoined extract of a private letter addressed to one of the conductors of this journal, by Mr. James Fleming, seedsman and florist of this city, dated London, July 25th, 1862.—Eds.]

I intended writing you a few lines before this, but really there are so many things to attract the attention in this immense city that one's time is wholly taken up by sight seeing. I have enjoyed my trip exceedingly, but as far as *climate* is concerned I prefer Canada. The weather here has been unusually cold and wet since the commencement of spring, and the crops have of course been affected accordingly. There are symptoms now of improvement, and if summer set in, in earnest, the harvest may form not far short of an average. My first impressions on seeing land on the Irish coast were not of the most pleasing kind, the landscape looked damp and black, the cold wet weather had kept back vegetation, and the coast appeared denuded of trees. However, the appearance of the farms and gardens very much improved as I got into the country, most of which is very pretty, and in favorable seasons highly productive.—We landed at Londonderry, a fine old town, surrounded by walls, occupying an important position in Irish history. After breakfast I walked round its walls and took rail for Belfast, which is a fine city, full of activity and commercial life, and which of late years has greatly increased. This is the centre of the

linen trade, and many thousands are employed in its factories. Quite a number of the operatives are unfortunately out of employment, in consequence of the American troubles. I was not fortunate in finding your friend, Professor Hodges, of the Queen's College, at home. The College is an extensive and handsome building, mainly of brick, with stone facings, not equal, however, to the university of Toronto, but based on the same non-denominational principle, and open freely to all. I had time to visit the Botanic Gardens close by, and was highly delighted with this interesting and beautiful retreat. It is mainly supported by subscription; government, I understand, affording little if any aid. Mr. Fergusson, the head gardener or Curator was very obliging, and the arrangements of the grounds and healthy state of the trees and flowers indicate the combination of no ordinary skill and industry. The *Auricularia Implicata* grows finely here, some noble specimens being 16 feet high, of beautiful proportions. Laurels attain to a great size, some fine trees 35 yards in circumference, and 25 feet high. Their red berries and verdant shewing foliage must contrast strikingly and pleasingly with the snows of winter.

From Belfast we proceeded by railway to Dublin, staying a day at an inland town called Dunganon. The country along this route is well cultivated and looks remarkably well. The potatoes, of which there is a large breadth, looked exceedingly promising, and I heard nothing of the disease. Hay and oats were a good crop; the former was being cut, but the difficulty seemed to be to cure it, in consequence of the damp, cloudy weather. Every expedient was tried to dry it; groups of laborers in the fields shaking out the mown grass with their hands. I saw no implements beyond the ordinary rake and fork, but was told that in some places, reaping, mowing, and tedding machines were employed, but which were unpopular with the laborers, who threatened them with destruction.—Dublin is indeed a fine city, favourably situated, and surrounded by a wide and beautiful country, interspersed with the splendid residences of the nobility and gentry. The Phoenix Park, immediately adjoining the city, and comprising 1400 statute acres, is a princely domain, with well arranged walks and drives, and beautifully adorned with magnificent groups of forest trees, and deer are to be seen by thousands. In these fine grounds is the residence of the Lord Lieutenant. My visit to the Royal Botanic Garden at Glasnevin, one of the many beautiful suburbs of Dublin, afforded both instruction and pleasure. The gardens are pretty extensive, with capacious green and hot houses; a new one of large dimensions is now in course of erection. The specimens of rare exotics are numerous and exceedingly fine, while the palms and other tropical plants have attained a great height, and are generally of beautiful proportions. This garden is mainly supported, I believe, by the Government, and the Curator, Mr. Moore, is a gentleman of distinguished attainments in all that relates to practical and orna-

mental gardening.—There is another Botanic Garden, in connection with Trinity College, an old and magnificent institution, arranged for the practical teaching of Botany, general and medical, which appears well adapted to its valuable purposes.

Leaving Dublin I crossed the channel to Holyhead in Wales, and from thence by rail to Chester, passing over the Menai Straits, a narrow arm of the sea dividing Anglesea from Carnarvonshire, through the celebrated tubular Bridge, which is a mean affair indeed compared to the later one at Montreal. This is an interesting ride, the highest mountains of Wales being visible in the distance. Passed the ancient cathedral town of Bangor, near which are most extensive slate quarries, and the residence of Col. Pennant of Penryn Castle, who has a herd of short-horns second perhaps to none in the United Kingdom. The gardens and grounds belonging to this princely residence are proportionately beautiful and extensive. Most of this country is only adapted to hill pasture, for small black cattle and heath sheep, the mutton of which is superb. The valleys are generally wide and beautiful, yielding heavy crops of grass and also of roots and grain; but at present in consequence of the ungenial state of the season, the crops in general look but indifferent.—I had an opportunity of staying part of the day in the fine old city of Chester, and of walking around its walls, which are still, notwithstanding their great antiquity, in a good state of preservation. Every street contains houses or buildings that are rare specimens of the old style, extending back many centuries. The soil around here appears in most places to be very rich,—the pastures appearing peculiarly so. It happened to be one of the market days for the sale of horses, the display of strong, heavy animals was very large; a description by no means generally adapted to Canada. From this to London we passed over, for the most part, a very fine country; the crops were better and forwarder, much of the hay having been secured, but, I was told, in rather indifferent order.—The English mode of hay-making involves a great deal of labor, which is conducted upon system; and it is surprising to a stranger how they succeed so well in making comparatively good hay in seasons like the present.

I remained in London eight days, during which time I was wholly taken up in sight-seeing, of which I can only be said to have made a commencement. I have neither time nor ability to describe any thing fully and must leave the magnificent Exhibition to abler hands. Although the Canadian department is small, and for mere display cuts a poor figure compared with some others, yet we have a number of good things, that attract attention, and have received a full share of medals. The one awarded to myself for a collection of agricultural and horticultural grains and seeds, I duly appreciate.

I afterwards proceeded to France, having a strong desire to see the gardens and horticultural operations in the vicinity of Paris. The

South of England had a beautiful appearance, highly picturesque: consisting of woods and pastures, orchards, hop-gardens, and corn fields, stately mansions, comfortable farm houses and neat cottages, often literally covered with the jessamines, ivy, honeysuckle and rose. In France I found the weather getting better and the crops more forward; in the more immediate vicinity of Paris they looked abundant. The farmers in forward situations were busy with harvest work.—In what little I saw of French agriculture the implements employed were exceedingly primitive and rude; but I am told that great improvement has commenced in these matters, as well as in the breeding of stock in some districts.

Paris is indeed a beautiful city, every thing so clean, and the public buildings and ornamental grounds are extensive and magnificent. I cannot attempt details. I spent a day at Versailles, far too short to afford but the merest glance at the Palace and Royal Gardens. The Parisians have excellent opportunities for relaxation and rational amusement in the city and its environs, which, judging from the vast numbers of people every day crowding the public places, they fully appreciate. The *Jardin des Plantes*, and *Vilmorin's Horticultural Grounds*, are exceedingly interesting and instructive to visitors, displaying great skill and systematic industry.

I shall depart in a few days for Birmingham, Manchester, and Sheffield, and when in the latter place hope to see Chatsworth, and shall afterwards proceed to Scotland. I must now conclude these hasty and very imperfect observations, trusting that I shall pick up information and a number of plants and seeds that may be turned to some good account for Canada, after my return.

### Farming Prospects Northwards

EDITOR OF THE AGRICULTURIST.—DEAR SIR, Having just returned from a trip to the foot of Lake Superior, I can give some opinion of the value of the country I have passed through as a farming country, and although to people who have made the same journey my remarks can have little interest, yet to those who have never seen the country they may be acceptable.

*From Toronto to Barrie* the crops looked exceedingly well, although I had seen and heard many complain that they would be ruined for the want of rain. On this section much of the fall wheat was cut, but still in the field, and on my return day before yesterday all was cut, and some housed. Every farmer that I talked to said much in favor of the fall wheat, especially, and most agreed in thinking the spring grain and roots would be a fair crop.

Looking at the wheat harvest going on I could not but think what a benefactor to this country, especially, was the man who invented reapers. The whole crop of fall wheat within a district can with their assistance be cut and

stacked within one week, without subjecting the Farmer as in old times to the annoyance and delay of cutting with cradles and reaping hooks at extravagant charges.

*From Barrie to Collingwood* the road runs through a most uninteresting country, very wet, and flat, chiefly sand and poor timber. With few exceptions, here I saw no fall wheat, indeed, no farming worth mentioning. I have frequently traveled the road before and each time formed the same impression. Collingwood is much improved, and the long wharf (where two steamers and some vessels are lying) covered with Western and Northern produce, much of it indeed Indian corn Chicago, gives one the idea of a business place, very different from that formed some years ago when visiting the "Hen and Chickens" as it was then called.

*From Collingwood to Owen Sound* the country is very pretty showing some, good looking farms and farm steadings. Here the steamer *Clifton* makes a daily passage each way, where only a few years ago the Indian canoe was the only boat. Owen Sound is becoming quite a town, with every evidence of prosperity about it.

*From Owen Sound to Shebananing* the scenery is very fine. The latter place is a little Indian village, apparently very old, and yet there are not ten acres of cleared land about the whole establishment. Strange to say the post office here is called Killarney, I suppose to please some immigrant or the whim of some traveller. It was originally called by its Indian name, and the post master allowed me to look at the old post office stamps which he has yet, and would be delighted to use again if permission were granted. Few things could display worst taste than the altering of the ancient and aboriginal names of this country; surely as much respect might be paid to the ancient tribes of this beautiful country, as to the wishes of old country people who desire to perpetuate old country names. At all events there are new places every day springing into being, where such names may be indulged in without injuring the feelings of a race not yet extinct, though fast degenerating and disappearing before the vast strides of Canadian civilization.

*From Shebananing to the Sault St. Marie* the country is as beautiful to the eye as it is worthless to the settler for farming or timbering. I must, however, make some exceptions in favor of the Sault, for I saw at the Hon. Col. Prince's, who is the judge of the new district of Algoma, some land as fertile as I ever saw. His peas are eight feet long, and everything else growing with equal luxuriance. The old Colonel or, as he is better known to many "Shot Accordingly" lives in good old English style, extending hospitality with open hands to rich and poor. As a settler he has done more than all the rest put together, as far as I could see. He has built a

good house and out houses, cleared considerable land and introduced a fine lot of good stock, very fine horses, thorough-bred Ayrshires and Galloways in horned cattle, Southdowns, and Leicesters in sheep, and poultry of the most improved kinds in great numbers. Indeed, as a settler his example is well worth following.

The Wellington Miners are doing an extensive business, no doubt at a large profit; but the Bruce Mines appears to be at low water mark and doing very little. In this neighborhood such a think as cultivating the ground is out of the question even for a hill of potatoes, as it is all rock just opposite the mines. St Joseph's Island affords a few people a living by farming, selling their little produce at the mines, which they reach by boats. It is said of forty thousand acres of this island, that about ten thousand is worth farming, but entirely cut off from all communication but by ice and small boats.

At one place where we called, near Garden River, named Sugar Island, we found a cunning Yankee who makes above a thousand dollar, per annum by the manufacture of raspberry jams which he makes from fruit gathered by the Indians, and which comes to him from all directions for miles around. I was told that some years he makes as much as six tons; besides this, he provides wood, milk, &c., for the boats passing up and down. The farmers about the Sault complain bitterly that no means have been taken by the government to establish a grist mill. I was told that some of them would join together and build one if Government would give the water privilege, which is about the finest in the world, and unbounded. This boon I can scarcely believe the Government will withhold if properly applied for.

Yours, &c.,

R. L. DENISON.

Dovercourt, Toronto, Aug. 9th, 1862.

### Galloway and Angus Cattle—The Provincial Exhibition, &c.

EDITOR OF THE CANADIAN AGRICULTURIST.

—SIR—I observe by the prize list that has been issued for the next Provincial Exhibition, that Galloway cattle are classed with Polled Angus cattle, and I confess I am at a loss to see what consistency there is in such an arrangement. They are acknowledged both in Scotland and England to be two different breeds, and are exhibited in separate classes. I have before me a Scottish paper containing a prize list of the Highland Agricultural Society of Scotland, (for 1860) in which prizes are offered for Galloway, and Polled Angus cattle in separate classes.

It would be quite as reasonable to class Durhams and Herefords together, as they are frequently the same colour and both have horns, while in the other case they are generally black and hornless.

It is really discouraging to farmers that have imported Galloways, and others who have paid

high prices for them and proved them to be an excellent and valuable breed, admirably adapted to the severe climate of our country, to find that the Board of Agriculture has disregarded their merits so much as to refuse to give them an equal position with the other breeds.

I might breed from large Durham cows and a Galloway bull and show those of their offspring that were black and hornless, as Galloways. This would not be right, although, in regard to points, grades are sometimes superior to thorough bred animals. But, as I have shown before, the principle is unsound, they are different breeds, and I claim that it is but right that they should be recognized by the society as such, and should receive the same privileges that are given to the other breeds. Another consideration is, that it places the judges in an awkward position, some of them may be prejudiced in favor of one breed and some in favor of the other for men are generally partial to the breed that they have been most accustomed too. This is especially the case with old countrymen. I should like to hear the opinions of other breeders of Galloways on the subject. And I hope that the Directors will give it an earnest consideration, and, if possible, make arrangements for having it changed before the fair.

You are doubtless aware that at the late exhibitions the judges have recommended that a register should be established for the pedigrees of Galloways. This matter ought to be attended to soon. As there is not a great number of them in the country yet, it would not be difficult to trace them back to the imported animals; but if it is neglected they will get scattered through the country, and there will be a danger of grades being passed for pure bred. Another thing that I wish to refer to, is, that at the last fair there were too many judges appointed for stock. Now for sheep there were two sets of judges to each class, and where persons are showing in three classes of sheep and two classes of cattle, it would require twenty men to show one man's stock to advantage. I am aware that a number of animals that were entered and would have taken prizes were not shown at all, simply because in the confusion of the hour it was impossible to get them out. Surely one set of judges is sufficient for one class. Yours &c.,

JOHN SNELL.

Chinguacousy, Aug. 5th, 1862.

[In reference to the foregoing remarks we would observe that Galloway and Angus cattle have been exhibited in the same class at our Provincial Shows frequently, in fact on every occasion on which the two breeds have appeared there together. The class was nominally for Galloways, but Angus cattle were entered along with them, and the two breeds were considered so much alike that no objection was taken. Last year, however, for the first time the A-

gus cattle were objected to, as competing with the Galloway, and as they were not nominally included in the class, they had either to be rejected, or special prizes awarded them. In order to avoid any difficulty of the kind this year, the words in the heading of the class are changed so as to include both breeds. We do not see that any injustice is done the Galloways. The only difference is that the prize list now includes by name cattle that were always before admitted by tacit consent. But if it is desirable to make a distinct class for the Angus cattle, no doubt it may be done in time. The number and sub-division of classes is already very considerable. Formerly there were only three classes for cattle, now there are six. But if a further sub-division is desirable, there is no good reason why it should not be arranged. We think our correspondent is in error in regard to the judges for sheep. We are not aware of there having been two sets of judges for any breed of sheep except Leicesters, and that has been the case with them for several years, on account of the large number entered in the class, which rendered it difficult otherwise to get through the work in time. As to the difficulty of exhibitors being always able to bring out all their different kinds of stock to each set of judges at the proper time, we believe our correspondent is quite right, and we shall be glad to see it remedied. We shall be glad to receive communications on such subjects from exhibitors and others interested, because it is chiefly by having the merits of every arrangement freely discussed, and the existence of defects communicated, that the managers of the exhibition can hope to arrive at a knowledge of what is necessary to ensure a tolerable degree of satisfaction in the work of the details.—  
[Ed.]

### Exportation of Short-Horns from America to England.

The importation of improved animals from England has long been deemed a desideratum among American breeders, and during the last fifty years many accessions have been made to our stock from English breeds. Such has been the attention bestowed upon the improvement of our stock, that we are at length enabled to reciprocate by exporting to England, for the use of English breeders, animals which have been brought to a high point of excellence by some of our distinguished breeders.

It is stated that Mr. Samuel Thorn, of Dutchess county, widely known as one of the most successful breeders of Short-horns in the United States, has made two shipments from his herd, which have resulted very satisfactorily, the animals selling at high prices. Mr. James O. Sheldon, of Geneva, who though entering upon the business at a later day, has nevertheless taken rank among our most celebrated breeders, has sent out several animals. One of these, a two years old bull, was sold to the Hon. Col. Pennant M. P., of Penryn Castle, Bangor, for 600 guineas, or over \$3000! A yearling bull sold for 400 guineas. The Duke of Devonshire purchased another at 400 guineas.

We scarcely know what higher honors could be achieved by American breeders than to be able to compete in England with the best animals bred there, and at prices quite equal to those paid for the choicest stock hitherto brought from the old country.

These facts do not at all prove that our importations of stock from England should cease. On the contrary, we do not doubt that mutual benefits will accrue hereafter from an interchange of this character. It must not, of course be understood that we are prepared to furnish any very large number of animals such as would be sought after by the English breeders; but the fact that we have a few to spare proves the important advance made in this country in the improvement of our farm stock.

### Rocky Mountain Silk Weed.

We gave some particulars relating to this plant in a recent number of the journal, see page 389. We are indebted for the following additional correspondence to the "Annals of the Botanical Society of Canada," published at Kingston.

COMMUNICATION FROM HIS EXCELLENCY LORD MONCK, ON A FIBRE PLANT SUITED TO THE CLIMATE OF CANADA.

I. Letter from Denis Godley, Esq., Secretary to His Excellency Lord Monck, Governor General of Canada, to Professor Lawson, Secretary of the Botanical Society of Canada:

Quebec, May 16, 1862.

Sir,—I am directed by the Governor General to transmit to you herewith a copy of a letter which was addressed to Lord Lyons by Doctor Hart, and which Lord Lyons forwarded to His Excellency.

Some of the seeds of the plant to which Doctor Hart alludes, are also enclosed.

His Excellency thinks it likely that the Botanical Society of Canada, of which you are Secretary, may be interested in this matter, and will cause the seeds to be sown with

a view to testing the value of the plant bearing them.

I have the honour to be, Sir,  
Your obedient Servant,

DENIS GODLEY,  
*Governor's Sec'y.*

GEORGE LAWSON, ESQ.,  
&c., &c., &c.

II. Letter from Frederic W. Hart, M. D.,  
St. Louis, to Lord Lyons.

*St. Louis May, 1st, 1862.*

My Lord,—Feeling that Her Majesty's Government is deeply interested in the cultivation of Cotton in the British Provinces, and having, during a sojourn in the Rocky Mountains these last three years, discovered a plant that excels cotton in length of fibre or staple, firmer in texture, and fine as silk,—I determined to plant a few seeds taken from the wild, and last year found to my satisfaction, that the bulbs or bolls, which in the wild plant are about the size of hens eggs, under culture grew to the size of a turkey or goose egg, and bore twice the quantity of silk that the Mississippi plant bears of cotton.

I gathered four pounds of silk from the plant, and saved a quantity for seed, some of which I herewith forward you.

On my return to the U. S., I was robbed by the Indian Kiowas on the plains. They stole my silk but left my seed.

The silk weed of the Rocky Mountains grows on the creek bottoms, pushes out in June, and ripens in September, October, and November.

It grows about five feet high, wild. It does not branch in the wild state, but it branches under cultivation and bears full and large bolls or pods.

The seed is all on the outside of the silk, and slips off at a touch, leaving the most beautiful silk I ever saw.

It can be cultivated on the St. Lawrence bottoms, Canada, and in Upper Canada, the whole country is suitable for its cultivation, the climate being similar, and even warmer than that of the localities where I discovered the plant.

As an old Cotton Planter of Mississippi, having raised ten crops in Yazoo, in Mississippi, my brands invariably commanding the highest market price, I feel the fullest confidence in recommending this seed for cultivation in the Canadas, and to the attention of Her Majesty's Government.

Should your Lordship require further information on this subject, I shall be happy to continue this correspondence.

I remain, &c.,

(Signed), FREDERIC W. HART, M.D.  
To Lord Lyons, &c.; &c.

III. Letter from Professor Lawson, Secretary of the Botanical Society of Canada, to Denis Godley, Esq., Secretary to His Excellency Lord Monck, Governor General.

KINGSTON, 22nd May, 1862.

SIR,—I had the honor to receive your letter of the 16th May, with accompanying copy of letter addressed to Lord Lyons by Dr. Hart of St. Louis. And I have to request that you will convey to His Excellency Lord Monck, the best thanks of the Members of the Botanical Society for the information which he has done them the honor to communicate, and for the accompanying seeds.

I have also to state, that in accordance with His Excellency's wishes, the seeds have been sown in the Botanic Garden here, with a view to testing the value of the plant as a source of fibre. The crop will be watched with care, and duly reported upon to His Excellency, so soon as the results can be obtained.

In the meantime it may be desirable to indicate briefly the probable character of the plant, and what likelihood there is of its becoming useful.

An examination of the seeds shows Dr. Hart's fibre plant to be an *Asclepias*, of which genus there are many species, inhabiting different parts of the American Continent, all producing a greater or less amount of fibrous material, usually of great beauty and lustre; and fibre-yielding plants of allied genera occur in India and elsewhere.

The beautiful silky material contained in the seed pods of *Asclepiads*, has necessarily attracted attention in this as in other countries, but, as attempts to spin it failed, its use in the arts has hitherto been confined to the stuffing of pillows and beds, and such-like purposes, among the settlers. There is every reason to believe, however, that the silk cotton of our *Asclepiads* may now be economised for spinning purposes, and therefore a greater interest is to be attached to Dr. Hart's plant at the present time than would have been necessary a few years ago.

The results of experiments that have been made in India, and by manufacturers in England, with the silk cotton obtained from an allied plant, the *Calotropis gigantea*, or Mudar Plant of Bengal, (which is essentially an *Asclepias*), offer inducement to attempt the raising of *Asclepias* fibres in Canada. The silk-cotton of the Mudar Plant is now becoming an article of export from India for the manufacture of a light substitute for flannel, and has been employed by Messrs. Thresher & Glenine, of London, for this and other manufactures, as appears from the remarks, of Dr. Alexander Hunter made at a meeting of the Madras Agri-Horticultural Society on 15th

January last. The Mudar material works well with either silk or cotton, and is now known in commerce as Mudar Silk Cotton. There is no reason whatever why the silk-cotton of Dr. Hart's plant, and the silk-cotton of our indigenous Canadian *Asclepiads*, should not prove as applicable to the purposes of the manufacturer as the silk-cotton of India.

It is desirable to observe that the silk-cotton found in the pod of *Asclepias* represents only half its riches as a fibre plant. A beautiful, and apparently very valuable, fibre is also obtained from the stem, which I am inclined to regard as of even greater importance than the silk-cotton itself; it is of quite a different character from that found in the pods, being not cottony nor so glossy, but of much greater strength, resembling in fact not cotton but flax. One of our Canadian species, *Asclepias incarnata*, has been experimentally cultivated with a view to the production of fibre, and the results of the experiments have been given by Judge Logie in the second part of the Botanical Society's Annals, page 87. Specimens of the fibre were exhibited by Mr. Freed, to the Hamilton Association, in 1860, and the Report of Mr. McMiking, a paper manufacturer, is given in Judge Logie's paper, shewing the fibre to be strong, flexible, silky, of a beautiful high color, brilliant lustre, and easily bleached, in fact to good for paper making, but of undoubted utility and value as a fibre. This species is still under experiment in the Botanic Garden here.

The success that has attended the use of the Mudar flax in India, (as well as the Mudar cotton,) seems also to hold out a strong inducement to the use of *Asclepias* flax in this country. The Mudar flax, from its tenacity, is called "Bowstring Hemp" in India, and is one of the strongest fibres known. Dr. Hunter, who has carefully studied the vegetable fibres of India for many years, states that it possesses most of the qualities of flax, and can be worked with the same machinery, as the fibre splits to almost any degree of fineness with the hackle, and bears dressing and beating well. For many years it was employed by the wealthy natives in India for making strong cloths, cambrics and lawns, worn by the Rajahs, and is still employed for making fishing lines, nets, gins, bow-strings and tiger-traps, on account of its strength. It does not rot readily in water, as the resinous milky juice of the plant seems to preserve it.

Other Indian *Asclepiads* likewise yield fibre of great strength, which seems to be partly due to the presence in the plants' juice of an organic product similar in physical properties to caoutchouc or gutta percha.

Judging from the observations and experiments of Dr. Hart, on the Silk Cotton Plant

found by him on the rocky mountains, and from the results of experiments that have been made by others on allied species—on *Asclepias* flax in Canada, and on *Asclepias* cotton and flax in India—it is not unlikely that both *Asclepias* flax and *Asclepias* cotton may ultimately become important materials of export from Canada. The *Asclepiads* grow luxuriantly in a wild state throughout Canada, especially in the western parts, and being strong-growing perennial plants, they are capable of easy cultivation, and would require not a tithe of the field-labour necessary for the growth of common flax.

Permit me further to mention that in addition to the seeds sown in the Botanical Garden, some have also been sent to members of the Botanical Society in other parts of Canada, for trial, and copies of your communication, with Dr. Hart's letter, have been furnished to the members, with a view to enquiry, and to observation and experiment on Dr. Hart's *Asclepias*, as well as on the indigenous species of our country.

I have the honor to be, Sir,

Your most obedient humble servant,

GEORGE LAWSON, Ph D., LL.D.,

Sec. to the Botanical Society of Canada.

DENIS GODLEY, Esq.,

Secretary to His Excellency Lord Mock,  
Governor General of Canada.

*List of samples accompanying the above Letter.*

1. Mudar Silk Cotton, from *Calotropis gigantea*. From Mr. Jaffrey, of the Agri-Horticultural Garden, Madras, India.

2. Canadian Silk Cotton, from *Asclepias Cornuti*. Kingston, C. W.

3. Canadian Silk Cotton—another kind—from *Asclepias incarnata*. Hamilton, C. W. Judge Logie.

4. *Asclepias* Flax—Canadian—in the rough state, unhackled and unbleached, from stem of *Asclepias incarnata*, the same plant which yields Cotton No. 3. Hamilton, C. W. Judge Logie.

*Written for the Canadian Agriculturist.*

**Hints for an Agricultural Report of the Township of Hamilton.**

*Continued from page 424.*

Of root crops the most important is the potato. This crop has become, especially on low heavy damp soils, a very uncertain one, it was first attacked with the still mysterious disease here in 1843, and since then it has never been entirely free from it, though some years it is much more so than others; on the high, dry, and

light soils in the township the potato is grown to some extent for sale, but on all heavy soils only for home use. In nothing is there a greater number of varieties than in the potato, every one almost has their favorite sorts—red, white, and blue kinds have all found advocates; we have found some of the early kinds and early planted to do best, they seem less subject to disease, and get ripe before the Fall rains set in.

The next root of importance is the Swedish turnip; about half as many acres are sown with them as are planted with potatoes; their cultivation has greatly increased. When we first knew the township, we doubt if there was a single acre grown in the whole township, (putting them altogether), now almost every farmer grows less or more of them, some to the extent of ten acres. They are all but indispensable for keeping stock in proper condition during our long cold winters. The fly is the greatest enemy the turnip grower has to contend with. They are sometimes damaged by lice, grasshoppers, and mildew.

The cultivation of both Carrots and Mangold-wurzels are on the increase, and seem to be grown to nearly the same extent; they are rather a more certain crop than the Swedish turnip, seldom attacked by fly, and (especially the carrots) stand our summer droughts better. Of carrots, the orange, red, and white varieties are all grown, but the white is most common, and attains the largest size. Of mangolds, the yellow globe, and long red are the favorite kinds though other varieties are grown. Likewise sugar-beets and parsnips to a small extent. The same may be said of beans, of which it appears there were seven acres grown in the township in 1860.

There is sufficient hay grown for home use, and to supply the towns in the neighborhood. There is little timothy grown for seed, that being mostly purchased by our farmers, but clover seed is grown to some extent, and in favorable seasons does well; we have seen crops of clover seed in all quantities, from seven pounds to upwards of seven bushels per acre, and sold at all prices, from three and a-half to ten dollars per bushel.

So much for our crops. The *weeds* that are most troublesome to us are the Canada thistle, the Charlock, and couch grass which are all prevalent in some parts of the township, and are all hard to extirpate once they have got a foothold.

**Draining.**—Much of the land in the front parts of the township would require thorough draining, and would be greatly improved by it. Several of our farmers have tried it less or more, the materials used in filling, were at first stone or wood or hollow bricks, now, tile is used; it is made in an adjoining township. Mr. J. Wade has drained to some extent, and finds it profitable. Mr. Hume laid about ten thousand tiles last year, besides what drains he had formerly

made. Mr. A. Crawford has sunk nearly three hundred pounds in drains, using first, hollow bricks, and now tiles. Mr. Fowler thoroughly drained one of his fields some time ago, which made a marked improvement on it. Mr. S. Campbell, when in this township, drained extensively, using mostly wood for filling, tiles were not to be had then. Mr. Wm. Roddick, Mr. Alcorn, and many others have drained to some extent, and we believe all who have tried it have found it profitable, and are encouraged to proceed and enlarge their operations; much however, is still needed, indeed *thorough draining* can hardly be said to be fairly begun yet.

**Fences.**—The great majority of our fences are the old, useful, though certainly not elegant worm fences which are general all over the Province, but many are now fencing largely with posts and boards, or post and pickets, and posts and poles; our main roads are mostly lined with such fences, there are likewise some good stone fences in the parts of the township where stones are plentiful.

Thorn hedges have been tried but have not proved very successful. Mr. Geo Roddick, Mr. Carr, Mr. Wade and Mr. John Wallace have all tried the English hawthorn, but none of their hedges are very thriving. Mr. Roddick's is the most thrifty of any we see, and it is hardly a good fence; some seasons the thorn plants are attacked and the leaves eaten up by a caterpillar, at other times by a small slug similar to the slug that sometimes attacks our cherry trees, and sometimes the mice know the bark during winter, thus completely killing them in places, so that we believe there is not yet a thorn hedge in the township that can be called a good fence. A live fence is very desirable, a plant that would for this purpose prove useful and ornamental is much wanted. Would not some of our native thorn if properly trained answer? We think a native plant indispensable. Willow hedges are sometimes tried, and the present year Mr. Wade has planted out a white cedar hedge.

Having thus gone over stock, crops, &c &c., we would note briefly our Implements. On the first acquaintance with the township, the farmer that had a Waggon, Plough, Drag, or pair of Harrows, Fanning-mill, Cradle, Scythe, pitch and dung-fork, and a few hoes and rakes had a complete set of farm implements; now many of them have Reaping, Mowing and Thrashing machines, Clover-cleaners, Seed-drills, straw and root cutters, Cultivators, Horse-hoes, Horse rakes, Rollers, Subsoil-ploughs, and many others, so that the value of farming implements in the township is set down by the late census at nearly ninety thousand dollars, and we think it rather under, than over stated.

It would be interesting to know who first introduced our various improved implements, but as we do not know this, we may briefly state what we have heard on the subject. Of course, on the first settlement of the township

such implements were not needed, nor could be used; it is only after the land has been cleared that many of them could be of any use. Of threshing machines, we have heard that the first travelling one was brought in here from the State of New York, in 1832, and we think there was only one travelling here on the following year, after that they became common, many of our more enterprising farmers procuring them; of course they were inferior to the kinds now in use, being all the old open kind that sent out grain and straw all mixed together. The first of Pitt's separators was brought in by Mr. J. Livingstone, formerly a resident of this township, about 1841 or 42. This kind with various improvements has now mostly superceded the use of all other kinds; they are mostly driven by horse-power, a few by water, and now this season, Mr. Alcorn introduced one driven by a travelling steam engine, it has not been sufficiently tested to prove its superiority over horse-power.

**Reaping Machines.**—The first reaping machine brought into this township (we believe the very first ever brought into the Province) was a Hussey's Reaper, brought for the harvest of 1843, by Mr. Daniel McKeys. It proving successful, a second of the same kind was brought in the following year by Mr. Wade. They both proved good useful machines for that time, but great improvements have been made on them since then. In 1847 several of the McCormick reapers were brought in, but they hardly answered expectations, performing far inferior to Hussey's. The manufacture of reaping machines on a pattern similar to McCormick's was begun by Helm & Son, in Cobourg, about 1848, and their machines were soon spread over the neighbourhood. Since then many different kinds have been tried with more or less success, many of them being made in Port Hope and Newcastle, besides imported ones. The most common here are Hussey's, Manny's, Burrall's, and self-rakers; they have proved a great boon to the farmer, lightening his labour in the most trying season of the year. Mowing-machines were introduced soon after the reapers, numbers having been made both in Cobourg and Port Hope, besides those brought from a distance; of this class there is not so much variety used—Ketchum's patent being the most common though some few other kinds are used.

The revolving Hay-rake was first introduced here about 1840, and proved a very useful labor-saving implement, indeed, we know of none among our various improved implements that saves so much labour at so small a cost, as it; they are now to be found in the hands of almost every farmer, and are used not only for raking stubble, but also to some extent for pulling peas; the kind mostly used is the wooden revolving rake. An iron spring tooth kind was brought in shortly after the wooden ones, but has not been found so useful, and is now seldom used, and if used, only for raking stubble. There is one of "Delano's" Independent Horse rakes used.—

This rake is mounted on wheels, the driver riding on it, and with his foot causing it to drop the hay; it answers very well; but whether it will supercede the revolving horse-rake remains to be seen.

Cultivators of various kinds for using on land that has been ploughed in the Fall, or on summer-fallow, and likewise, drills, cultivators or horse-hoes, for working between the rows of corn and root crops are in general use, many of them being made in the township.

**Michigan Sod and Sub-soil ploughs.**—Sub-soil ploughs, Seed-drills, Rollers, and indeed we may say, almost all improved implements are used in the township. In conclusion, we would notice briefly our Agricultural Societies, forming part of the County of Northumberland. The farmers of this township have always taken a prominent part in the management of the County Society. In looking over the transactions of the first Society ever formed in the county, dating as far back as 1828, we find six or seven names from this township on the committee; and in the present County Society, formed in 1837, our farmers have always taken an active part; it was not till 1847 that a township Agricultural Society was formed. In that year they gave premiums for root crops in the field, (a plan that has ever since been followed) their funds not admitting of a general Show. The Provincial Show being held in Cobourg in 1848, all the funds were that year given to it. The first Show of the Township Society was held at the Court House, on the 31st October, 1849; a show has been held every year since, except in 1856 when the Provincial Exhibition was again held in Cobourg.

Our shows have gradually increased in size and interest, until now there are over 800 entries, and a prize list of upwards of \$500. The Society numbers about 200 members, each of them receives a copy of the *Canadian Agriculturist*, published twice a month. In connection with the Agricultural Society, we would notice the Farmers' Club that was kept up for several years in the township. In looking over the pages of the *Newcastle Farmer* (which, by the way, was published in Cobourg, and edited by a farmer of our township, the late Thos. Page, Esq.,) we find that the first meeting of the Club was held at the Town Hall, Cobourg, on the first Saturday of July, 1846, when the subject of "the preservation and application of manure," was fully discussed. Mr. J. Wade was Chairman, and Mr. W. Creighton, Secretary, to the meeting, and Messrs. H. Ruttan, M. Jellet, Eyre, and Phillips, appear from the Report to have been the chief speakers; though several other meetings of this club were held, we have no further report of their proceedings. After a time this club seems to have fallen through, but it was again revived, or rather a new one started, about 1851, principally through the exertions of Messrs. Hume, Page, and Wade, and this was well kept up for several years, its discussions being mostly

published in the *Cobourg Star*, and frequently copied into the *Canadian Agriculturist* and other papers. Many papers containing a vast amount of valuable information were read before the Club, by Mr. R. Hume, Messrs. Page, J. Wade, P. R. Wright, J. Sutherland, G. Black, and others. We would state that the reports of this club, which were generally acknowledged as correct, were drawn up by a common working farmer,—we mention this for the encouragement of other clubs, who are often deterred from getting out reports of their proceedings from having no reporter.

In observing the various casualties to which our crops are subject, which no knowledge can foresee nor human skill prevent, we are often impressed with the thought, that no class of the community are so daily, so visibly dependent on the hand of God as the cultivators of the soil. A mysterious blight falls upon the potato, the plant withereth; the worm consumes our crops in their early origin; a tiny fly attacks our wheat when just heading out; the rust arrests it when nearly ripe; storms of rain and thunder lay the most promising of our crops low; the promised harvest of our fields droop beneath the corrosive influences of minute agencies; even after the crops are cut, a series of bad weather disappoints the hopes of the year—the just expectations of the farmer. Daily therefore are we conscious of the need of God's superintending care, but while we feel this dependence, still we are encouraged to apply our industry and skill to improve the gifts the beneficence of Providence bestows; and in a most remarkable degree we are enabled to reproduce those gifts—as the promised seed time and harvest never fail—so that as there have ever been, so there will be to the end of time "Seed to sow and bread to eat."

W. R.

Cobourg, June 18th, 1862.

TABLE No. 1.

Premiums awarded to the Township of Hamilton at the Provincial Exhibitions, held at:

|            |      | Classes. |     |     |    |   |        | Total. |
|------------|------|----------|-----|-----|----|---|--------|--------|

Number of acres under cultivation \$40,891

### The Agricultural Census.

From *Toronto Globe*.

A blue-book has been out for some time, giving for Upper Canada the agricultural statistics collected at the taking of the census in January, 1861. Those collected for Lower Canada are still unpublished. A few of that facts, however, ascertained with reference to that section of the Province, were supplied by Mr. Galt in his budget speech of last session. These we shall repeat, before proceeding to the results of the Agricultural census of Upper Canada, in order that as complete a view as possible may be pre-

sented of the progress in agriculture made by the entire Province. The comparison of course is between the years 1860 and 1851, the figures given to the enumerators as to the average under cultivation, the amount of produce raised, &c., being in each case for the year previous to that in which the census was actually taken.

In Lower Canada, then, according to Mr. Galt, the lands held were 10,223,959 acres in 1860, against 8,113,408 acres in 1851—an increase of 2,110,551 acres, equivalent to more than 20,000 lots of one hundred acres each. The acres under cultivation were 4,678,900 in 1860, against 3,605,167 in 1851—somewhat over a million of acres of previously wild lands having been brought under cultivation during the intervening period of nine years. The cash value of farms in Lower Canada in 1860, was \$168,432,546, and of live stock, \$24,572,124. The bushels of wheat raised were 3,073,943 in 1851, and 2,563,114 in 1860—a decrease of 510,829 bushels. Of other grains, (barley, rye, peas, oats, buckwheat, and Indian corn,) the number of bushels raised was 12,147,070 in 1851, and 23,534,903 in 1860—an increase of 11,387,633 bushels. Of flax, the product in 1860 was 976,495 lbs., against 145,755 lbs. in 1851.

The blue-book to which we have referred, enables us to enter more in detail with regard to the agricultural progress which has been made by Upper Canada. The number of occupiers of lands in Upper Canada was 131,983 in 1860, and 99,906 in 1851—an increase of 32,077, or a little over 32 per cent. This was considerably less than the percentage of the increase of the whole population, which was 46 $\frac{3}{4}$ . It is a singular circumstance that the number of very small landholders diminished considerably between 1851 and 1860. In the former year there were 12,417 occupiers of 20 acres and under, and to the latter year there were but 7,099 of this class. The number who held between 20 and 50 acres was 19,143 in 1851, and 26,630 in 1860; the number who held from 50 to 100 acres increased from 47,427 to 64,891; the number who held from 100 to 200 acres increased from 17,515 to 28,336; and the number who held above 200 acres increased from 3,404 to 5,027. The whole of the lands held in Upper Canada were 13,354,907 acres in 1860, against 9,825,915 in 1851—an increase of 3,528,992 acres, or nearly double the corresponding increase in Lower Canada. The following are the counties in which the greatest increase in the quantities of land held has taken place. In Kent the increase was from 216,422 acres to 315,222; in Lambton, from 167,969 to 291,803; in Victoria, from 160,190 to 292,765; in Simcoe, from 330,103 to 466,694; in Wellington, from 358,949 to 532,671; in Huron, from 284,037 to 632,324, an increase of 348,287 acres; in Grey, from 217,319 to 585,697, an increase of 368,378 acres; and in Bruce from

35,643 to 477,882, an increase of not less than 442,239 acres. The county in which the smallest quantity of land is held is Russell, which has also the smallest population of any county in Upper Canada—its population being 6,824 and its occupied acreage, 72,715. The county in which the largest quantity of land is held is Huron, which has also the largest population of any county in Upper Canada (excepting York)—its population being 51,954, and its occupied acreage 632,324.

A point of greater importance than the increase in the amount of lands held, is the increase of lands brought under cultivation. In this respect Canada West very far outstripped Canada East. The acres under cultivation in Upper Canada in 1851 amounted to 3,702,788; in 1860, they amounted to 6,051,619—an increase of 2,368,831, or 43 $\frac{1}{2}$  per cent. In Lower Canada the increase of lands under cultivation was below 30 per cent. In 1851 the quantity of cultivated land in Upper Canada exceeded the quantity of cultivated land in Lower Canada by only 97,621 acres; in 1860 the excess in favour of Upper Canada was no less than 1,372,719 acres. It will be observed, too, that the work of bringing land under cultivation went on in Upper Canada in a much more rapid ratio than even the increase of population, the proportion being as 63 $\frac{1}{2}$  to 46 $\frac{3}{4}$ —the natural inference from this being that Upper Canada is a more decidedly agricultural country now, in proportion to its population, than it was ten years ago. More than one-half of the total increase of land brought into cultivation is found in the following thirteen counties, which we have arranged in the order to which they are entitled by the amount of industry in felling the forest that has been put forth within their respective limits. In Huron the acreage under cultivation was 54,976 in 1851 and 215,325 in 1860—an increase of 160,349 acres. In Wellington the acreage under cultivation was 119,081 in 1851 and 232,346 in 1860—an increase of 113,265 acres. In Perth, the acreage under cultivation was 58,116 in 1851 and 166,419 in 1860—an increase of 108,303. In Grey, the acreage under cultivation was 30,499 in 1851 and 133,885 in 1860—an increase of 103,386. In Oxford, the increase was 96,826 acres; in Middlesex, 96,725; in Simcoe, 93,120; in Bruce, 86,968; in York, 71,577; in Hastings, 69,032; in Ontario, 61,471; in Lanark, 60,363; and in Welland, 60,064. The following are the five counties in which the increase of cultivated lands was smallest. In Prince Edward, the increase was 29,704; in Lincoln, 26,674; in Halton, 21,713; in Prescott, 21,014; and in Russell, 14,687. In each of the following nine counties the number of acres under cultivation in 1860 exceeded 200,000. In York the cultivated acreage was 292,213; in Middlesex, 233,672; in Wellington, 232,346; in Oxford, 231,058; in Huron, 215,325; in Northum-

berland, 206,900; in Ontario, 205,353; in Durham, 205,107; and in Simcoe, 202,312. In each of the following nine counties the cultivated acreage was under 100,000. In Glengary, it was 99,880; in Lambton, 96,092; in Bruce, 89,230; in Renfrew, 85,461; in Stormont, 80,071; in Essex, 77,105; in Dundas, 76,700; in Prescott, 53,934; and in Russell, 20,712.

Of the 6,051,619 acres under cultivation in Upper Canada, 4,101,902 were under crops, 1,860,848 under pasturage, and 88,869 in gardens and orchards. Of cultivated lands, therefore, in Upper Canada, the average proportion under crop was  $67\frac{3}{4}$  per cent, and that in pasture  $30\frac{3}{4}$  per cent. In 1851, the proportion was  $61\frac{1}{4}$  per cent under crop, and  $36\frac{3}{4}$  per cent in pasture. In 1860, the proportion of lands under crop to the whole quantity under cultivation was highest in the following eight counties: In York the proportion was 80 per cent; in Brant  $79\frac{1}{2}$ ; in Bruce,  $76\frac{1}{2}$ ; in Grey, 76; in Simcoe  $75\frac{1}{2}$ ; in Peel,  $75\frac{1}{2}$ ; in Perth,  $74\frac{1}{2}$ ; and in Welland,  $73\frac{1}{2}$ . The proportion of lands in pasture to the whole quantity under cultivation was highest in the following five counties: In Glengary, it was 41 per cent; in Grenville, 41; in Lanark,  $42\frac{3}{4}$ ; in Elgin,  $44\frac{1}{2}$ ; and in Stormont, 47. The following six counties occupied the first rank, with reference to the attention paid to gardens and orchards. In Hastings, 6,450 acres were occupied in this way; in York, 5,004; in Middlesex, 4,741; in Oxford, 4,639; in Norfolk, 4,387; and in Welland, 3,875. The six counties in which least attention was paid to these matters were Bruce, which had 388 acres occupied with gardens and orchards; Glengary, which had 295; Carleton, which had 285; Prescott, which had 213; Renfrew, which had 104; and Russell, which had but 64 acres so occupied. Column 17 of the abstract gives the quantity of land held by townspeople, not being farmers. This, we suppose, is in addition to the figures already stated, and for the whole of Upper Canada, makes a total of 182,552 acres.

Of the whole 13,354,907 acres held in Upper Canada, upwards of one-half, or 7,303,288 acres, were in 1860 still uncultivated and returned as "wood and wild lands." An examination of the column, showing the location of these lands, owned by private parties, but not yet cultivated, will give some idea of the localities in which the greatest accessions to the present population of Upper Canada will be found, when the next periodical census is taken. The nine counties, in which there are the largest quantities of granted lands still to be cultivated are as follows: In Grey there are 451,812 acres of such lands; in Huron, 416,999; in Bruce, 388,652; in Wellington, 300,325; in Middlesex, 287,681; in Renfrew, 275,186; in Lanark, 265,691; and in Simcoe, 264,382. The counties in which there is now the smallest quantity

of wild lands to be brought under cultivation, are as follows: In Wentworth, there are 85,625 acres; in Welland, 82,428; in Prince Edward, 77,215; in Brant, 75,517; in Halton, 73,518; in Lincoln, 68,451, and in Russell, 52,003.

### Steam Cultivation—The three Systems.

*To the Editor of the Mark Lane Express.*

SIR,—To all interested in steam cultivation—and what farmer is not?—it was a pleasant sight at Farningham to see the land smashed to pieces or laid over in deep even furrows without the treading of a horse's hoof: to see the most perfect cultivation rapidly performed by the sole agency of steam. It was most gratifying to walk from field to field, admiring the skillful adaptations and masterly workmanship displayed by our enterprising English implement makers.

Everyone who visited the trial-fields must have felt that steam cultivation has assumed a much more practical form since last year; and also, to some extent, a more perplexing one. The question no longer lies merely between Fowler's plan and Smith's; other men are in the field, and most of these have a variety in their several systems: so that it is no easy matter, after determining to join the ranks of steam cultivators, to make up the mind in which company to enlist.

That each system represented at Farningham is capable of executing first-rate work will not be doubted by any who examined the land operated upon; but it should be carefully borne in mind, that *the character of the work done depends on the implement rather than on the system*. I name this particularly, because the natural tendency of a farmer's mind is to judge by the results on the land, of which he feels himself perfectly competent to form an opinion.

I consider that the first thing we have to do is, to determine which system is best adapted to our own farm, and then to decide on the most appropriate implements. Let us consider this more particularly.

All the systems which have come prominently forward may be included under one or other of the following heads:

- 1st—Traction System,
- 2nd—Direct System,
- 3rd—Round-about System.

The Traction system, in which the engine traverses precisely the same ground as the implement, was not represented as connected with cultivation; it was—where it ought to be—working, in exceptional cases, on the hard road.

The Direct System, of which Fowler may be regarded as the champion, and in which the engine and anchor travel along opposite headlands, was well represented, and presents many advantages: in economy of power, diminution of wear

in rope, and economy of manual labour ; and, for tolerably level tracts of large open fields, must, I conceive, at present distance all competitors. But farms consisting entirely of large well-arranged open fields are the exception ; and when we consider the irregularities of surface on the majority of farms, the obstacles offered by small enclosures, irregular quality of land, wear and tear in moving machinery, danger of priming, &c., from the frequent variations in the level of the engine boiler, absorption of power in climbing hills, difficulty of traversing soft or boggy land, complexity of the machinery placed in the hands of farm labourers, and last, but not least, the first cost of the apparatus, we shall see that the Direct System, while possessing many advantages, labours in very many farms under insuperable disadvantages. Fowler, in his disc anchor windlass, and ingenious adaptation to the ordinary portable engine, has met some of these objections, by diminishing the cost and the weight. Coleman's mode of working with a pair of implements is included in this system, and exhibits a simple method of avoiding the necessity for a heavy anchorage on the headland opposite to the engine ; but the fact of its requiring a duplicate of all implements, employed is no slight objection, and the absence of any arrangement for coiling the rope, the small size of the drums, and the difficulty in the way of efficient portering must add fearfully to one of the most serious items in steam cultivation,—viz, the wear of the rope ; while the general objections to the Direct System apply to it equally with Fowler's.

The roundabout system, in which a portable engine is stationary and the rope laid round the field, was well represented by Smith, Howard, Fowler, and others, each employing a different kind of windlass, and all, as well as the implements deserving especial attention. For simplicity and general adaption no system can at all compare with this ; the entire apparatus being comparatively inexpensive, and soon understood by a labourer of ordinary intelligence. The engine employed is similar to that used for thrashing, and there are few fields in which it is not easy to find some spot well adapted for placing an engine and windlass, and conveniently accessible for the water-cart ; while in many cases, the expense of water-carting may be avoided, by the formation of a tank or hole to retain or reach the water. The remainder of the apparatus, such as anchors, snatchblocks, &c., is simple, effective, portable, and little liable to get out of order ; add to this the small amount of first outlay required, and the advantages of the roundabout system can hardly fail of having great weight with the practical farmer in making his decision ; but at the same time he must not lose sight of the fact, that, under it, the manual labour is more, and the length of rope exposed to constant wear greater than under the direct system.

In these remarks I have abstained from noticing many details in the several systems, because it has been my aim to avoid all that might tend to lead the mind away from the first great question : " Which of the three general systems is the best for my own farm ? " This being settled, we have advanced one most important step, and it only remains to determine which maker we shall go to, and which of that maker's plans we shall adopt, which questions can only be resolved by each individual for himself, with special reference to his lease, his farm, and his purse. My own farm I cultivate with Howard's apparatus, for which I consider it specially adapted ; but of this I am convinced—that where no obstacles are presented in the shape of a tag end of a lease, annual tenancy, or the incapacity of the farmer, there are, comparatively, few farms in the country, on which one or other of the systems of steam cultivation might not be adopted with very great advantage.

My present object is not so much to consider the novelties in steam cultivation as to urge its general importance, and to rouse farmers from that torpid state in which so many yet remain with reference to it, *especially our heavy clay land men*, whose land, horses, and pockets pray so earnestly for the invaluable adjunct of a steam cultivator.

Before concluding, allow me to draw attention to one important feature in the trials, which gives rise to much misconception in the minds of farmers.

Provided the implement does not penetrate into the hitherto uncultivated "pan," we can, by inspection, form a tolerably near guess as to the power required to move it at a given rate ; and if it does not penetrate below, we know that *each extra inch enormously increases the power required*, especially if we have tried our hand at subsoiling by horse-power. But when we enquire what power is employed, we are so often met by the answer, "Oh, a common 8 (or perhaps 10) horse-power engine;" and if we further enquire the pressure, "About 45lbs." is generally the reply. Perhaps in some cases it is about 45lbs., but how often is it about 70, 80, or 90 lbs., or even more ; and I suppose even balance springs and even registers do not always like to contradict the assertions of their employers.

I have before said that the *quality* of the work done depends on the implement rather than on the system ; but the *quantity* of the work done by any given implement must, to a great extent, depend on the system, and what we want to know is—1st. What power is really exerted by the engine, not merely the nominal horse-power ; 2ndly. How much of that power is absorbed by the intermediate machinery, such as clip-drum, windlass, pulleys, tight and slack rope, &c ; 3rdly. What *effective* pull remains for the implement, be it plough,

cultivator, or any other? This investigation was ably touched upon by your correspondent in the lucid article which appeared in your columns last year, and it is very desirable that it should be gone into most fully. Now the amount of effective pull and speed attained being two things of the utmost importance to be ascertained, and the draught being steady, why not attach a sufficiently powerful dynamometer to the rope in front of the implement, and another behind? Then let the most convenient implement for the purpose be selected, and tried in succession under each system of haulage; this done, let such various implement be attached in succession to the same rope. Surely a few experiments of this nature, conducted by competent men, would materially assist the agricultural world, and simplify the question of steam cultivation: they would exhibit to us where the system was in fault and where the implement, which is just what we want to get at. When prizes are offered, and judges appointed, makers would not hesitate to submit their machinery to this or eal; but individual farmers are not in a position on the trial field to come to a satisfactory conclusion. An engine, whether working at 30lbs. or 90lbs., looks very much the same, while the hanging on of eight or ten additional horses to a machine would strike the most unpractised eye; but we must never forget that whether an engine works at 30lbs. or 90lbs. makes a very material difference to the length of its life. Steam engines are like horses: moderate food and regular work will enable them, like our farm horses, to do a fair amount, and last a good many years: high feeding and harder work will make them break down the sooner, like our London horses. True it often pays better to act on the latter principle, but the farmer must not suffer himself to be deceived by the results achieved by "an ordinary 8 horse power engine." He will also be wise, in purchasing an engine, to bear in mind the purpose for which he intends it, viz., for cultivating as well as thrashing, &c. Engines well adapted for the latter may be ill adapted for the former; but those well adapted for the former will do at least equally well for the latter; hence he should have an eye to the *substantial* character of his engine, and also endeavor to procure the greatest amount of power with the least amount of weight: perhaps he can hardly do better than go to a first class maker, explain his wants, and leave it in his hands to supply them.—I am, Sir, your obedient servant,

W. B.

### The British North American Colonies at the International Exhibition.

(From the *Mark Lane Express*.)

The British North American Colonies have made a noble display of their products at the International Exhibition, and have quite thrown

into the shade the United States. Few persons who have not visited our possessions on the other side of the Atlantic could have given them credit for the skill, enterprise, and ingenuity displayed in the various mechanical contrivances and manufactured articles, of which they have sent specimens. But it is not with these that we would deal on the present occasion. We desire rather to call attention to their agricultural products and capabilities, and shall touch upon those of the Lower Provinces, leaving Canada for subsequent notice. It is the first International competition in which the four Colonies of Nova Scotia, New Brunswick, Prince Edward Island, and Newfoundland have taken part.

The province of New Brunswick we have noticed on some former occasions. The Commissioners of the Colony have sent home very fine specimens of its cereals, pulse, maize, flour, and meals, with agricultural implements made and used in the Colony—such as mould-board ploughs, horse rakes, and barrows. There is also a good collection of its timber shown rough and manufactured. The amount of land cultivated in New Brunswick does not yet produce anything like a sufficiency of food for the maintenance of the population. This has not been because agriculture has not been remunerative, but because of the apparently greater inducements held out to the mass of the people by other branches of industry. Lumbering and ship-building, however, are giving place yearly in a greater degree to agriculture. The number of farmers is rapidly on the increase, and a determination seems to have taken hold of every branch of society to leave no efforts untied for the development of this most important—this greatest branch of industry.

In each county of the Province there is an agricultural society—in some counties more than one—and there has lately been established a Provincial Board of Agriculture, for the purpose of watching and protecting the interests of the farmers generally. The annual reports of these societies speak in high terms of the increase that is taking place in the number of farmers; the improvements made in the qualities of crops, and the interest that is being manifested amongst the farmers; and there is every reason to hope that hundreds and thousands of persons will be induced in a few years to enter upon the valuable lands now lying waste, and improve them; thereby enriching themselves and benefiting the country.

The farmers of New Brunswick are all, so to speak, in good circumstances. Many of them are rich, and are now enjoying the fruits of their labour of former years. The majority of them are men who commenced life twenty or thirty years ago with literally nothing. They went into the woods; the first clearing they made was a few yards whereon to build a hut;

that done, their clearing has gone on extending year after year (the hut being replaced by a commodious frame house), until now it counts a goodly number of broad acres, whose fertility enables their owners to live in plenty, oblivious of the trials that surrounded his early life, and rejoicing in the prosperity Providence has bestowed upon him through his own exertions.

Although the soils vary, and one kind of land may be better suited for growing the valuable cereals than another, yet everywhere, except on the barrens or in the swamps, fair crops of these may be raised. But no matter where the farmer settles down, if he is careful, industrious, and persevering, he will meet with an ample return for his labour. If the district in which he resides does not produce wheat as abundantly as he may wish, it will yield a good crop of corn; or failing this; buckwheat may be the most remunerative; if neither of these, it will produce potatoes or turnips, or vegetables of some kind in such quantities as will leave him no cause for complaint. In many places crops of all kinds may be raised to great advantage.

With reference to agriculture, there is one thing that, in justice to the soil of North America, or its climate, or both, should not fail to be mentioned. In no matter what part of the country a piece of land may be situated, or how poor it may be, it is capable by a little labour judiciously disposed, of being brought to a high state of agricultural perfection. As an example, the State of New Hampshire may be cited, justly termed the "Granite State," in consequence of the predominance of granite, which seems to cover its entire surface. Here, upon the solid rock, as it were, are farms that in appearance and productiveness can compare admirably with those of more favored climes. The "hanging gardens" of Eastern Rome are not more marvellous than those apparently bare rocks teeming with vegetable life. This productive power, which the most barren soil in America seems to possess, may be due more to the skill of man than either the causes mentioned above. It is certain, however, if it does not really exist in the soil, it is capable of being introduced into it.

The province of Nova Scotia, which makes its first appearance in European competition this year, has spared no expense whatever in bringing its resources and products before the general public. Its court, looking at the extent and resource of the colony, contains one of the finest colonial collections in the Exhibition Building, every article being well displayed and arranged. The fish, the wood, the minerals, the horticultural produce, the animals, are all beautifully shown, and the great moose standing at the entrance is an indication of its whereabouts. Its gold fields have lately brought the colony into more prominent notice; and with regard to expense in exhibiting, the provincial govern-

ment have given Messrs. Baring Brothers, the official agents of the colony, *carte blanche*.

Nova Scotia is peculiarly adapted for an agricultural country. The best lands are alluvial, or "dyked marsh," and "intervale." The former are formed by the deposit left by rapid tides of the Bay of Fundy, which rises in some places to a height of sixty feet.

The fertility of the "dyked marsh" is, it is believed, quite unparalleled. Some of it, such as the Grand Pre (the scene of Longfellow's "Evangeline"), was reclaimed by the Acadian French about two hundred years ago; and there are instances of this species of land having been cultivated a century without any manure. Up-lands top-dressed with this alluvial deposit may be cultivated for twenty years without any manure. "Intervale" land is formed by the deposit of fresh-water rivers, &c., and is exceedingly productive.

Potatoes in Nova Scotia will yield, on an average, about 230 bushels per acre, and have yielded as much as 450 bushels per acre of a very superior quality. This crop is not so much affected the potato disease as in other countries. 3,284,864 bushels were raised here in 1860. Twenty-two samples are shown by different exhibitors. Wheat, under very inferior cultivation, will yield from 25 to 30 bushels per acre. Specimens sent weigh 62 to 64 lbs. per bushel. The competitors in this department were very few, and the specimens sent are much inferior to those exhibited at the Provincial Exhibition in 1854.

The following is an extract from the official report—

"Every person who has any real knowledge of agriculture, and saw the specimens of grain entered at our exhibition, will readily admit that it was almost all of first-rate quality, and so rarely, if at all, inferior to any equal number of samples either in the mother country or the United States. The *Dumfries Courier* states that 60 lbs. per bushel for wheat, 50 lbs. per bushel for barley, and 40 lbs. per bushel for oats, have generally been considered a kind of standard or medium weight between the heavier and lighter quality; and it mentions, as a specimen of the present crop, that at last week's Haddington market samples of new grain were shown of the following extraordinary weights: Wheat 65 lbs. per bushel, barley 58½ lbs per bushel, and oats 48 lbs per bushel.

"Now the grain at our Exhibit on compares very favourably with this statement, as out of fifty-four parcels of wheat of various kinds, only two were below 60 lbs. per bushel, and to balance this, 16 parcels were above 64 lbs. per bushel, while two parcels were above 66 lbs per bushel. In barley they exceed us in one pound per bushel, our heaviest being only 47 lbs. and 14 ounces per bushel; but we equal them in white oats, as ours is 48 lbs. as well as theirs,

and then they admit it to be an extraordinary weight in Haddington, one of the greatest grain market is the South of Scotland, more especially for oats. Then we have twenty samples of Indian corn, mostly all very excellent, some of it weighing 53½ lbs. per bushel, and twenty-two samples of buckwheat all verging upon, and some of it quite 58 lbs. per bushel."

Barley is a sure and heavy crop; the bald barley will yield about 40 bushels per acre, specimens sent weighing 54 and 56 lbs. per bushel. Indian corn in the western counties prove a most profitable crop, yielding 60 to 65 bushels per acre; specimens sent weighing 60 lbs. per bushel. The climate of Nova Scotia is particularly suited for the growth of buckwheat, specimens sent weighing as much as 56 lbs. per bushel. All kinds of garden and field seeds grow remarkably well in Nova Scotia, producing excellent and profitable returns.

Prince Edward Island shows an interesting collection of its grain, dairy produce, and implements; and these are the most attractive, because, although an agricultural colony of some local notoriety, it is not much heard of here. The climate of the Island is highly favourable to the pursuits of agriculture and the health of the inhabitant. The main difficulty that has stood in the way of its progress and settlement has been the centralization of the land in the hands of absentee proprietors. A short notice of the history of the colonization and the land question difficulties may here be advantageously given.

The allotment of lands in the island was rather lavish—the plan of settlement by grants in August, 1767, being as follows: The island was divided into sixty-seven townships or parts of townships, with certain reservation to individuals having claims upon the Government, and others upon certain conditions of settlement and the payment of quit rents of 2s., 4s., or 6s. annually per hundred acres, commencing five years after the grant, and only half being required the subsequent ten years. The granters were to settle upon each lot one person for every 200 acres, within ten years. If one third of the land in that proportion was not settled in four years, the land was to be forfeited to the Crown. When the ten years had passed however, no attempt had been made to settle 48 out of the 67 townships. Repeated and complicated difficulties arose. Lands were sold for the quit-rents, unoccupied lands were estreated, a composition of quit-rents was attempted. But difficulties continued to exist, even after the reduction in the price of quit rents to 2s. per hundred acres announced in 1817. About ten years after, public improvements were pushed forward with great vigour; roads were widened and improved all over the country, bridges were built, agriculture was encouraged, improved stock was imported, and, to stimulate others, the Governor became a farmer.

In 1828 the Home Government sent out orders to enforce the arrears of quit rent due for five years, and stated to amount to £10,000. The House of Assembly and the colonists generally petitioned the King to relinquish the arrears, and in reply it was stated that the rents might be commuted for £1,000 a-year.

In August, 1861, the then commissioners appointed by Royal mandate to inquire into and adjudicate upon the subjects of dispute in respect to the tenure of lands on this island, brought their labours to a termination. The parties represented in the Commission were the Crown, certain large proprietors of lands on the island, and the tenantry acting through their Government. The claims of each party were minutely and patiently investigated—the grand design of converting on fair and equitable terms the leaseholds of the whole island into freeholds. The Commissioners recommended for this purpose the borrowing of £100,000 by the Local Government, with the guarantee of interest by the Imperial Government. Twenty year's purchase is the maximum price to be paid; but the land is to be valued by arbitrators.

According to the census of 1861, the population of the island was 80,556. The crops of 1860 yielded 346,125 bushels of wheat, 223,195 of barley, 2,218,578 of oats, 50,127 of buckwheat, 2,972,335 of potatoes, 348,784 of turnips, and 31,100 tons of hay. The live stock owned in the island consisted of 18,765 horses, 60,015 neat cattle, 107,242 sheep, and 71,535 hogs. 711,485 lbs. of butter were made in the year, and 109,233 lbs of cheese.

From Newfoundland much was not to be expected in the shape of agricultural produce—the fisheries being its main stay. But that it is not the bleak and inhospitable country supposed, is shown by the specimens of wheat, barley, and oats sent to the Exhibition by the Hon. L. O'Brian. That this island could greatly benefit agricultural interests by the manufacture of fish manure to take the place of Peruvian guano, which is now again running up in price, specimens of seal and cod manure deodorized are shown. There could be obtained from the refuse of the cod fishing alone, about 25,000 tons of manure in a perfectly dried state, and from the seal fishing, with dogfish and other refuse, two or three times as much."

### Our Forests—Their Importance.

The preservation of timber in the United States is becoming a subject of vast importance as affecting climate, agricultural products and the mechanic arts. In some portions of the Eastern States, which were originally covered with dense forests of valuable trees, timber is already quite scarce, and every year becoming more so. It is still abundant in the North-western States; but there, the same management

is rapidly producing the same result: the unsparing ax is busily engaged in its work of destruction, settlers seeming eager to get rid of the wood as soon as possible, and valuing their farms in proportion to the number of acres cleared. Consequently the same result may be expected as at the East, and the next generation will probably witness the same scarcity of timber and the same baneful effects from its absence that are now felt in other portions of the country.

As for the vast region stretching from the Mississippi, or even the Wabash, to the Rocky Mountains, it is well known that immense tracts are entirely destitute of trees, and it is perhaps safe to say that less than one-tenth of the whole district is timbered land.

Aside from the intrinsic value of wood and timber for the purposes of domestic economy, some interesting considerations arise from this improvident destruction of the treasure lavished upon the eastern portion of the continent by the hand of Nature.

It will hardly be denied that sterility, or at least a great depreciation of the soil, has followed the total destruction of timber wherever it has occurred on a large scale, in connection with tillage, particularly of those countries situated south of the 40th parallel of latitude—Syria, Persia, the North Coast of Africa, Spain, once fertile countries, according to history—might be adduced as instances.

A little reflection will convince us that a total destruction of woods and forests could hardly lead to any other result: water is an element that is absolutely indispensable to vegetable life. It is always within the power of man, by proper drainage and deep cultivation, to correct the effects of superabundant moisture; but rarely can he supply the want of it by artificial irrigation, except in a very unequal manner, far inferior to that afforded by the clouds, those great natural reservoirs, or by watering; a very laborious process, necessarily confined to small patches of ground.

Now it is well known that woods have the property of attracting electricity and of making clouds discharge their contents, particularly where they exist on elevated lands. Trees, by their shade and the leaves they deposit on the soil, prevent the action of the sun from drying the soil too rapidly, and the moisture is retained to be given slowly and beneficially to the adjoining lands. But this is only a part of the valuable agency of trees in agriculture; they act as natural wind-breakers, moderating its violence to a surprising degree, and preventing its carrying off the moisture of the earth.

In those parts of our country—Fond du Lac—which are timbered, winter wheat is an almost certain crop; not from the superiority of the soil over that of the prairies—for the latter are equally fertile—but simply from the protection afforded against the wind by the surround-

woods; the snow remaining a long time on the ground to protect the plants, and the soil retaining sufficient moisture to bring them forward till the berry matures, even in the driest seasons; whereas, on the prairie, no such protection exists; the snow that falls upon the ground is partly drifted to the woods, and the remainder rapidly disappears under the combined action of the sun and of winds that meet with no obstacle, and consequently sweep over the land with unchecked violence, drying up the soil and withering the plant. For this reason, it may be said that the cultivation of winter grains is entirely abandoned on the prairie; in this section at least, as experience has proved it to be unprofitable.

The same effect is produced, although in a more subdued degree with regard to spring crops; a dry season invariably affecting the open grounds of the prairie more injuriously than the timbered or the "oak openings;" for the obvious reason that on very open lands the winds carry off the moisture much more rapidly than on those places which are comparatively sheltered.

In mountainous or even hilly countries, the total destruction of timber is attended with the most lamentable results. Mountains receive far more water and snow from the clouds than the lowlands, and when their flanks are entirely denuded of the forests, which a beneficent Nature almost invariably plants there, the torrents produced by showers and melting snow meeting no longer with the powerful obstacles presented by the roots of trees, tear the sides of the mountains; deep ravines and land slides occur; and the floods, instead of depositing enriching alluvial matter in the valleys, roll upon them masses of gravel and sand which destroy their fertility; thus causing a two-fold mischief, viz: washing the mountain-side down to its primitive formation, where only a stunted vegetation can afterward subsist, and covering the rich lowlands of the valley with barren soil, besides filling the navigable channels of rivers with sand-bars.

The wonderful adaptation of the works of nature to the wants of man is strongly exhibited with regard to the vast prairies of Illinois, Wisconsin, Missouri, Iowa, which are so destitute of fencing and building timber; and yet, by their climate and the fertility of their soil, are capable of maintaining a dense population. The Upper Mississippi, and many of its tributaries, by which those states are watered, mostly take their source in Minnesota and Northern Wisconsin, in a country covered with dense forests of pine which are pronounced by most of those who have visited them, to be inexhaustible; so that everything is ready for the benefit of man: the easily tilled prairies to supply the lumberman with food, the lumber to supply the prairie farmers with building and fencing materials, and

the navigable streams to transport the needed commodities both ways.

Would it not, however, be prudent to take care not to exhaust this apparently inexhaustible supply of the products of pine forests? has not past experience demonstrated that they can and probably will be exhausted, and that too, more speedily than most people would suppose possible? Few persons, unless in the north-west, are fully aware of the magnitude which this lumbe trade has acquired, and of the ratio at which it is constantly increasing; and probably fifty years hence little of those valuable forests will remain.

I have thus adverted to a few of the evils threatened to the agricultural interests by the wholesale and indiscriminate destruction of timber now going on in most parts of the United States. I will not enter upon the discussion of many other interesting considerations which the question suggests, such as leaving the whole country bare of shade and foliage and unattractive to the eye, as well as the certain future scarcity of wood for fuel and timber, for fencing, ship and house building, and the many purposes for which it is indispensable in the mechanic arts. The subject is certainly important, in a national as well as an economical point of view. Certain it is that should the present wholesale destruction of timber go on increasing, as it bids fair to, with the increase of population, without the adoption of some plan to renovate those valuable forests, posterity will have little reason to thank us. No large extent of country, however fertile, can be very desirable as an abode to man without a fair proportion of timbered land. Wood is almost as necessary to civilized man as the bread he eats.—G. DE NEVEU, in *Cincinnati*.

### More Light Underground.

Science is intended to give us a shield against the ills of life. A people that sits still, and views their calamities as simple "*visitations*," must have fallen back upon the savage life. An Italian priest, called upon to bless a plot of land, where a few blades of corn were contending with the enemies which usually beset them on ill-managed soil, gave the applicant a sensible rebuke. "It is of no use for me to bless your land," said the priest; "what you want is manure." At one time the people of this country were accustomed to resign themselves piously to flood and draught. In these days of progress such *visitations* are regarded only as the proper punishment of indolence and slovenly management, since they have been disarmed by the drainer's tool and the two-inch pipe. Science has taught us to catch the lightning and conduct it innocuous to the ground. We shall probably at some future date control storms of wind and rain, and until we have found out the

secret necessary for this feat, we continue to insure ourselves against their effects, so that their fury, instead of being discharged with crushing force upon the shield of one individual, is received harmlessly upon the united shields of the many. We are continually finding out that we are not the sport of unseen powers to the extent we once held to be the case, or in the manner the peasants of Norway and Sweden believe themselves to be. We have learned that we need not propitiate the wind or the rain, the lightning or the frost, the fever or the fire. The Almighty has surrounded us by certain conditions, subversive of life, not that we should be victimized, but that, having the will, we should rise superior to them, and that in the act of battling with circumstances, we should undergo that discipline which is necessary to the full development of our manhood. We are superior to the elements around us. At one age or another man has regarded himself as the creature of circumstances; but experience has taught in so many cases that he is the master of circumstances, that he may well arrive at the conclusion that he is the master of all circumstances. As to "inevitable laws," there are very few such straight lines to constrain us, save our duty to the Great Maker, and for the rest laws are finite, and retain their supremacy only so long as human experience retains its present scope; to-morrow may change all, and either give us a new view which may result in a new law, and the abrogation of an old one, or such a view as shall change the application of the old law.

The farmer who, next to the sailor, seemed to be the most helpless and exposed of human creatures, has of late years gained considerably in this sense of mastership. While he has been busy in producing food, his friend the chemist has been unremitting in his attention to certain influences which for ever were opposing his efforts. These which were represented as antagonisms, and so impersonated, were discovered rather to be negative than positive influences: influences arising rather out of the indolence of man than such as specially aroused themselves to counteract his inactivity. Sir Humphry, Davy, Liebig, Lawes, and Gilbert, have each shown that nothing is wanted to save farmers from the losses to which they have been exposed, but such a knowledge of the agencies around them as shall enable them to work *with* them, to subject them to their will, and to use them for the production of desired results.

Perhaps no chemist has given the farmers more assistance in this respect than M. Boussingault. From the laboratory of that most persevering of experimentalists they have from time to time received highly valuable contributions to scientific discovery. Never has he given a record of experiments there conducted of greater interest than those recently published under the title *Agronomie, Chimie Agricole et Physiologie*. He has been directing his attention to

the composition of the air contained in the soil, to the absorptive properties of arable land, to an estimation of what amount, separately of ammonia and nitric acid is to be found in water, rain, snow, dew, and mist. The immense importance of such inquiries upon the future of agriculture, as tending to correct the present imperfect theories of manuring, must be apparent to any one whose mind is alive to the present state of the question.

It is usual to insist upon the presenee of ammonia as food for the growing crop; but little is known as to the circumstances under which it is presented most advantageously.

If it be allowed—and this will not now be disputed—that plants grow only by addition of cells, and that these cells, consisting of two parts, owe their outer part or protection to the union of carbon and water, or its elements, and their inner part to ammonia, or its elements, nitrogen and hydrogen, it is obviously important to discover the manure in which nature works to supply this highly vitalized internal membrane, that we may learn how best to assist her. Although the elements of Ammonia are plentiful in the air, hydrogen by the decomposition of water to unite with nitrogen, M. Boussingault's experiments have brought him to the conclusion that the cell is not supplied with it directly from the atmosphere. Ammonia must be accounted for from elsewhere. In the course of his researches he says, that he found the seed to be a perfect storehouse of nitrogen and phosphorus, and of all the characteristic materials of the vegetable species whose seed it is. In virtue of the existence in it the seed grew in a chemically pure air and barren soil, and although fed only with pure water, developed into a perfect plant, which flowered and ripened seeds with no more nitrogen than was in the seed to begin with. It is well to remember that there is usually from five to six per cent. of nitrogen in the seed, while in the entire plant there is one per cent.

The experiments he made upon fertile soils abound with practical suggestions. As with the atmosphere so with the soil: although four-fifths of its bulk is nitrogen, plants can appropriate nothing from the atmosphere save a few stray particles of ammonia floating in it. In a fertile soil, similarly, there may be 96–100ths of nitrogen, “locked up from the plant in organic compounds, which the plant cannot decompose.” Boussingault very justly says, on this evidence, that analyses of soils and manures, detailing the quantity of this constituent or of that, afford information really of little value to the farmer, who must seek to know the *conditions* in which they are found there, whether free or in bondage. He comes to the conclusion that the only sources of nitrogen, and those from whence the vegetable cell is composed, are ammoniacal salts and nitrates. Phosphates, he insists are indispensable in every case, and nitrogenous matter is also needful as a companion

to the nitrate. “A nitrate is preferable to an ammoniacal salt, inasmuch as nitrogen appears to be fully assimilable by plants, and being more fixed is less likely to be lost than ammoniacal salts, all of which are more or less volatile.”

We are scarcely aware how much depends upon carbon, and how important it is for a sufficient quantity to remain free to combine with and fix the ammoniacal salts and nitrates in the tissues of the growing plants. Unless it is at liberty to perform this good office, such elements as these may exist to repletion in the soil without benefit to the plant. Carbon, however, serves a more important purpose still. As food plants, to whose existence it is essential, it can only become assimilated and combined with oxygen, that is as carbonic acid. Boussingault then details some interesting experiments suggested by this fact, to find the quantity of carbonic acid which exists in the air of the soil. One set of experiments he devised to prove the *quantity* of air held by soils of various kinds; another to ascertain the *quality* of that air. His evidence and substance with regard to the first set is as follows: The average for fair soils may be stated at 400 cubic yards per acre, taken at a depth of 14 inches; the entire volume of the acre taken to this depth is equal to 1,750 cubic yards; so that in such a soil the contained air is about a quarter of the density which it is in the superincumbent atmosphere. Soils very rich in humus and recently manured gave the largest quantity of unfixed air, sands and clays the least. With respect to quality, the experimenter found more carbonic acid in the air of the soil than in the atmosphere. In the latter it is usual to allow 4 parts carbonic acid in 10,000 atmospheric air; but a soil rich in humus contained 974 in 10,000, the soil of a meadow contained 179, and no soil, according to his experience, run short of 100 parts. Striking an average, the air contained in one acre of arable land, 14 inches deep, equalled 1,750 cubic yards; soil manured a year previously contained as much carbonic acid as is found in 9,446 cubic yards of the atmosphere; so that the acre of soil lately manured contains as much as there may be estimated in 60 acres of the atmosphere 14 inches deep.

Before referring to the conclusion deduced from such premises, there yet remains one point of special interest elucidated by these investigations. In comparing the oxygen of the air confined in the soil with that in the atmosphere, it was found that the latter is always deficient in this busy-body constituent by nearly the same quantity as goes to combine with carbon to produce carbonic acid. It is also not irrational to suppose that oxygen, beyond burning the carbon of the organic remains in the soil, unites also with the free hydrogen to be found there, and thus ministers to the wants of the rootlets in the matter of water as well as of carbonic acid. This service is more important than at first it appears

to be; since were carbon and oxygen to combine in the presence of the nascent hydrogen—that is to say, were there not sufficient members of the oxygen family to ally with those of the carbon family on the one hand, and the hydrogen family on the other—the unallied members of the hydrogen family, in their single life, might be productive of considerable damage. If that hydrogen can be utilized as water, all is well; but if left alone, it becomes the victim of other bad spirits, and produces such combinations as formic acid, humic acid, and acetic acid, which so acting are destructive of life.

For the agriculturist, there is but one practical conclusion for all this. He will readily infer that the soil, in order to fertility, must contain a notable quantity of organic matter, which the atmosphere, by a process of slow combustion, may transfer into carbonic acid and water, and ultimately into nitrates and ammoniacal salts. "Organic matters, when submitted to the united influence of air, moisture, and a suitable temperature, give rise to carbonic acid and water; and if nitrogenous, to ammonia. When buried in a soil sufficiently open, their combustion is so obvious that, in warm climates, it may happen at the end of some years that a clean soil, rich in humus, becomes so poor as to be unable to give a crop without the application of manure. Thus mould, humus, and all the last terms of the putrefaction of vegetable substances, are so many sources which emit carbonic acid; and it is beyond doubt that an important part of the efficacy of organic origin ought to be attributed to this remission, whether it be that the acid gas absorbed by the roots runs the course of the organism of the plant, or that, turned into the surrounding atmosphere, the light decomposes it under the influence of the leaves which assimilate the carbon." It is very easy to regard, therefore, every particle of humus in the soil as "a focus from whence carbonic acid gas is constantly emanating" to modify that atmosphere which descends from above, and fit it for its mission to the roots which pervade the seed-bed in search of support for the wondrous development of woody fibre, green leaf, tender blossom, and perfected seed. F. R. S.—*Express*.

### The Advantages Derived from Shading the Soil with Green Crops.

We have frequently contended—and the additional experience which every year brings with it further confirmation to the fact—that the rapid exhaustion of even our very best soils is not due so much to constant cropping as to the hoed crops which play so prominent a part in our system of agriculture. It is true that corn and tobacco draw largely upon our soils, and especially upon the phosphates and the potash which they contain. It is true, also, "that shallow and careless cultivation has done much to

assist in exhausting lands which were regarded at one time as of almost in exhausting lands which were regarded at one time as of almost inexhaustible fertility," and statistics likewise show that whilst the area of cultivation has been extended year after year, the average product per acre has diminished.

One of the primary reasons why these crops have proved so deleterious to the soil, is the fact that the system of cultivation required to bring them to perfection, keeps the intervals between the growing plants utterly bare during the hottest months of the year. The action of the sun upon these exposed surfaces, together with the constant stirring of the soil for the purpose of keeping it loose and light and friable, whilst it promotes the solubility of its plant-food, yet at the same time exposes the organic and inorganic substances which constitute in their several proportions the elements of fertility to great loss, both by evaporation and by washing rains. As an illustration of this process of exhaustion by the simple exposure of bare soil to the action of the sun and the rain in summer time, we may cite the following facts. A piece of land kept constantly ploughed, without any crop whatever being grown upon it, if not suffered to grow up in weeds, will gradually lapse from a state of fertility into one of comparative barrenness. It has been losing year after year, by evaporation and by leaching rains, the greater portion of its plant-food, its vegetable and mineral wealth, if we may be permitted to so term it. As a signal proof of this we have in our mind's eye a peach orchard which twenty years ago was planted upon as fine a piece of soil as is to be found anywhere within ten miles of Baltimore. It was a light, loose chocolate soil, and the quality when the orchard was originally planted, was that of the best tobacco land. That orchard was ploughed regularly every season to promote the growth of the peach trees, and to facilitate the ripening of the fruit. It is the usual custom with the best peach-growers. In twelve years, or by the time the peach trees began to show signs of decay, those fifty acres bore every evidence of a soil that had been utterly exhausted. Yet with the exception of the peach trees themselves, not a single crop of any kind had been taken from the land. Now, this rapid exhaustion could not be charged to the demands made upon the soil by the peach trees alone, but to the fact that the soil was kept perfectly bare throughout the summer.

Again—take the converse of the proposition. So long as lands are kept shaded they continue to increase in fertility. Does any one doubt this? Let him turn out an old field, and after a while a new growth of wood and brush will spring up, except when the land is worn into gullies, and with the growth of this wood, the

droppings of the leaves and the shade of the foliage, a portion of the lost fertility will be restored. Yet the trees have been drawing nutriment from the soil all through these years. Take another instance—leave a bed of corn-stalks, or a pile of brush, upon a field that the previous season had been planted to corn, and is consequently bare of herbage or weeds: or, build a fodder stack in the field and fence it off from the cattle. When the land comes into crop again the next season, the place from which that pile of stalks, or brush, or fodder stack, will show a racker growth than any other part of the field. What was the reason of this difference?—nothing more than that the ground was kept shaded, evaporation was prevented, the soluble salts were retained, and the land got the benefit of them.

Instances of this kind are constantly coming up before the eyes of the observant farmer and from them he may draw the following conclusions, for they are susceptible of none other:—

First—That the exposure of the soil to the sun, heat and rain of our semi-tropical summers rapidly exhausts it of its fertilizing elements.

Second—The covering or shading the soil preserves those elements.

Third—That green crops, such as clover, should take the place of hoed crops more frequently in our system of husbandry, and that the less frequently the surface of the soil is exposed to the wasting influences of the sun, wind and rain, the longer it will retain its original condition of fertility.—*Baltimore Rural Register.*

### Grazing.

The art of grazing embraces the practical solution of two important problems, viz., 1st, how to obtain the greatest amount and best quality of herbage from any given pasture; and 2nd, how to consume this herbage by live stock, so as to make the most of it. The grazier has ever to keep in view what is best for his land and what is best for his stock; and must take his measures throughout the entire season with an eye to both these objects. As regards the first of them, experience yields the following maxims for his guidance:—

Never to stock his pastures in spring until genial weather is fairly established.

Never allow the grasses to run to seed, nor parts of a field to be eaten bare, and others to get rank and coarse.

Duly to spread about the droppings of the cattle; to remove stagnant water, and to extirpate tall weeds.

Some time about midsummer to make a point of having the pasture eaten so close that no dead herbage or "foggage" shall be left on any part of it.

In what more immediately concerns the wel-

fare of the live stock he is in like manner taught in stocking his pastures.

To adapt the stock as regards breed, size, condition, and numbers to the actual capabilities of the pasturage:—

To secure the stock at all times a full bite of clean, fresh grown, succulent herbage.

In moving stock from field to field take care that it be a change to better fare—not worse.

Pasturage consists either of natural herbage or of "seeds." In the south-eastern counties of Scotland there is little good old grass: all the really fertile soils being employed in arable husbandry, with the exception of small portions around the mansions of land owners. The pasturage consists, therefore, for the most part, of the cultivated clovers and the grasses. Comparatively few cattle are there fattened on grass, the object graziers being rather to stock their pastures with young and growing animals, and to get them into forward condition for being afterwards fattened upon turnips. The grazing season is there also much shorter than in England, old grass seldom affording a full bite for a well conditioned bullock before the middle of May, or later than the middle of September. It is quite otherwise in England, various parts of which abound with old grass lands of the very richest description, on which oxen of the largest class can be fattened rapidly. These, in many cases, admit of being stocked towards the end of April, and under judicious management continue to yield excellent pasturage for half the year. When stocked with cattle in fresh condition, two sets or "runs" are not unfrequently fattened, in such pastures, in the same season. These grass-fed cattle begin to come to market early in July, and for four or five months thereafter constitute the chief supplies of beef in our markets.

Cattle already well fleshed are alone suitable for turning into these rich old pastures. When this is attended to, and care taken not to overstock the pastures until they yield a full bite, the progress of the oxen will usually be very rapid. It is now customary to hasten this progress by giving about 4lbs. of oil-cake to each beast daily. The dust and crumbs being sifted out, the bits of cake are strewn upon the green sward, from whence they are quickly and carefully gleaned by the cattle. This is usually a profitable practice. It brings the beasts forward rapidly, and proves their appearance and handling, and, besides enriching the land, admits of about twelve per cent. more numbers being fed upon a given acreage. These choice old pastures are usually occupied in combination with others of inferior quality. The most forward lot of cattle having been fattened and sold off from the former, they are ready to receive a fresh stock. If it is contemplated to get them also fattened before the expiry of the season, they are not put on the best land instantly on the first lot being sold;

but a crowd of sheep or store beasts being turned upon it for a few days, the existing herbage is cleared off, and the pasture (*Anglic*) "laid in" or (*Scottice*) "hained," until a fresh, clean growth fits it for receiving a suitable number of the best cattle from the other pastures. It is inexpedient to graze sheep promiscuously with cattle on these best lands, as they pick out the sweetest of the herbage, and so retard the fattening of the oxen. Neither do we approve of having horses among such cattle; not so much from their interfering with their pasturage, as from the disturbance which they usually cause galloping about. This does not apply to the draught horses of the farm, which are usually too tired and hungry when turned out from the yoke to mind anything but feed and rest; but it is better thrift to soil them; and frolicsome mischievous colts are unsuitable companions for sedate, portly oxen. In favourable seasons the grass often grows more rapidly than an ordinary stocking of cattle can consume it, in which case they select the best places and allow the herbage on some parts to get rank and coarsen. If these rank places are neglected until the herbage gets dry and withered, the finer plants die out, the coarser growing grasses usurp the ground, and the pasturage is injured for future years. To check this evil in time, these neglected places should be mown, and the grass either brought to the homestead for soiling, or left to dry where it grew, in which state the cattle will eat up most of it, and be the better for it, especially if their bowels are unduly relaxed by the succulence of the growing herbage. The remarks now made apply equally to all old pastures employed for the fattening of cattle, although not of the first quality. All that is required is to observe due proportion betwixt the capabilities of the pasturage and the breed and size of the cattle. A pasture that will fatten a five-stone ox may be quite inadequate for one of seventy, and the hardy Galloway or West Highlander will thrive apace where the heavier and daintier short-horn could barely subsist.

With the exception of the best class of rich old pastures, grass is usually consumed to greater profit by a mixed stock of sheep and store cattle than by one kind of animals only. This holds true both as regards the natural herbage of pastures or water meadows, and cultivated grasses, clovers, or sainfoin. When old pastures are mixed "seeds" are grazed chiefly by sheep, the same rules apply that have already been noticed in connection with cattle. The herbage should, if possible, be fully established in a growing state, and so far advanced as to afford a full bite before the pasture is stocked in spring. If the sheep are turned into it prematurely their close nibbling hinders the plants from ever getting into a state of rapid growth and productiveness, and the stock of roaming over the whole field, and keeping long afoot before they can

glean enough to appease their appetite, is prejudicial alike to them and to their pasture.

The prudent grazier endeavours to avoid these evils by having his stores of swedes or mangles to last until the full time at which he may reckon on having good pasturage. In distributing the flocks to different fields, the best pasturage is allotted to those that are in most forward condition. It is advantageous to have the pasture so subdivided that one portion may be double stocked while another is rested. By frequently removing the stock from the one portion to the other the herbage of each by turns gets time to grow and freshen, and is more relished by the sheep than when the whole is tainted by their uninterrupted occupation of it. In the case of clover, trefoil, sainfoin, and water meadows, this principle is yet more fully carried out by folding the flock and giving them a fresh piece daily. The crop is thus eaten close off at once in daily portions, and the plants being immediately thereafter left undisturbed, and receiving over the whole area their due share of the excrements of the flock, grow again more rapidly than when subjected to constant browsing under a system of promiscuous grazing. This plan of folding sheep upon such crops has the same advantages to recommend it as soiling, only that it is cheaper to shift the fold daily than to mow and cart home the forage and carry back the manure. In the case of water meadows it is the practice to irrigate them afresh as each crop of grass is fed off. This is attended with considerable risk of the sheep getting tainted with rot, which must be guarded against as much as possible. In the first place, it is well to give them a daily allowance of bran, beans, or cake, and salt; and besides this to put on this land only such sheep as are nearly ready for the butcher. They will thus fatten very rapidly, and be slaughtered before there is any harm to ensue.

The modes of grazing which we have now described are appropriate for sheep in forward condition. The poorer pastures are usually stocked with nursing ewes and lean sheep bought in from higher grazings. Lambs both before and after weaning, require clean pastures, and of course, frequent changes. If kept on tainted pastures they are certain to become subject to diarrhoea, or to be stinted in their growth, and to have their constitution so weakened that many of them will die when afterwards put upon turnips. To avoid these evils they must be frequently moved from field to field. A sufficient number of store cattle must be grazed along with them to eat up the tall herbage and rank places avoided by the sheep. After the lambs are weaned, the ewes require to fare rather poorly for a time, and thus can be made use of to eat up the worst pasturage and the leavings of the young and fattening sheep. When the latter, with the approach of autumn, are put upon aftermath, clover stubbles, rape, cabbages or

turnips, their previous pastures should in succession be thickly stocked by the ewes and other store stock, so as to be eaten bare, and then get leave to freshen and get ready for ewes by rutting time, when they require better food. In depasturing sheep on poor soils it is usually highly advantages to give them a daily allowance of grain or cake in troughs, which must be shifted daily, so as to distribute the manure regularly over the land. By means of this auxiliary food sheep can be fattened on land the herbage of which would not alone suffice to do this. It admits also of a larger number of sheep being kept per acre, and of the pasturage being fed off more closely than could otherwise be done. The produce of poor silicious soils, both in grass and after crops, is much increased by the additional manuring and treading which the consumption of such extraneous food upon them occasions.

It is always advantageous to have pastures provided with a shed under which the stock can find shelter from sudden storms, or from the stacks of insects, and the scorching rays of the summer's sun. When such sheds are regularly trewed with dried peat or burnt clay, much valuable compost for top-dressing the pastures can be obtained. The dung of the cattle thus secured and applied benefits the pastures more than that which is dropped upon it by the animals. Such clots require to be spread about from time to time.

To carry out successfully the various details now referred to, which constitute the art of grazing, there is required much foresight, accurate observation, sound judgment, and constant superintendence. Without all this it is impossible to make the most of any given amount of live stock and pasturage, and hence the extraordinary disparity in the results obtained by different graziers from similar materials.

The temperate climate of Britain is so peculiarly favorable to the growth of the grasses and other pasture plants, and to the keeping of live stock with safety in the open fields for the large part of the year, that the practice of consuming these crops by depasturing, as already described, has hitherto been decidedly preferred to soiling. One consequence of this is, that forage crops have been comparatively neglected. There is now, however, a growing conviction among agriculturalists that it is more convenient to keep neat cattle and horses during summer in yards or loose boxes, and to feed them with succulent forage mown and brought to them daily as it is needed, than to turn them adrift to browse in the fields. The pasturing plan is preferred by many because it involves the least labour, and is alleged to be more healthful to the animals. In behalf of the soiling plan, it is urged that a given space of ground under green crops keeps nearly twice as much stock when its produce is mown and consumed elsewhere than when it is constantly nibbled and trodden upon; that

housed cattle being exempted from the vicissitudes of hot weather, the attacks of insects, mutual disturbance, and the labour of gathering their food, eat less and yet fatten more rapidly than they do at pasture; that more good is gotten of their excrements when mixed with litter and trodden down under cover than when dropped about in the open fields; and that land from which a green crop has been mown, when ploughed up is freer of weeds and (other things being equal) bears a better crop than that which has been pastured. It is a further recommendation to the soiling plan that it admits of oilcake or meal being administered along with green food with a precision and economy that is unattainable in the pasture fields.

There being so many and such cogent reasons in favor of the practice of soiling, we may warrantably anticipate that it will in future be much more generally adopted. It is proper, however, to notice that the success of this system is absolutely dependant on the following conditions. The green food must be mown and brought home at least *twice* a-day, owing to the rapidity with which it ferments when put together; it must be given to the stock not less than *four* times daily, and only in such quantity at each feed as they can eat clean up in the interval betwixt meals; they must have constant and ample supplies of pure water and fresh litter; and, in particular, matters must be so arranged that there shall be an unfailing supply of green forage of the best quality through the entire season. This is accomplished either by successive cuttings of one kind of crop from the same ground—as of irrigated meadow or Italian ray-grass—or by a combination of such crops as naturally come to maturity in succession, or are made to do so by a sequence of sowings. From what has been said, it is obvious that soiling can only be carried out successfully with a moderately good soil and climate, a liberal use of manure, and skill and foresight on the part of the farmer. With these, however, its results will usually be highly satisfactory. It is peculiarly adapted for clay soils, on which the culture of root crops is attended with much difficulty, and where there is, therefore, abundance of litter for use in summer, and much need for the soiling system to get it converted into good manure.—*Willson's British Farming*.

## How to Calculate the Value of Manures

FROM PROFESSORS HODGE'S FIRST STEPS TO CHEMISTRY.

The following are the prices per ton at which the chief ingredients of manures in a state of purity may be estimated. These prices, it must be recollected, will be influenced by the fluctuations in the rates to which the commands upon which the calculation of their value is based are

subject. They, however, may readily be corrected, and will enable farmers to obtain a close approximation to the money value of manures.

VALUE PER TON OF THE INGREDIENTS SHOWN BY ANALYSIS TO EXIST IN GUANO AND ARTIFICIAL MANURES.\*

|                                                                                                   |         |                                                                            |
|---------------------------------------------------------------------------------------------------|---------|----------------------------------------------------------------------------|
| Water .. .. .                                                                                     | £0 0 0  | } Dependent upon the amount of ammonia which they are capable of yielding. |

| Organic matters destitute of nitrogen, and not capable of yielding ammonia by their decay .. .. . | £0 10 0 |                                                                            |
| Ammonia .. .. .                                                                                   | 56 0 0  |                                                                            |
| Phosphate of lime .. .. .                                                                         | 7 0 0   |                                                                            |
| Phosphate of lime rendered soluble .. .. .                                                        | 25 0 0  |                                                                            |
| Alkaline salts, when chiefly soda compounds, .. .. .                                              | 1 0 0   |                                                                            |
| Potash .. .. .                                                                                    | 20 0 0  |                                                                            |
| Common sulphate of lime, (gypsum unburnt), .. .. .                                                | 1 0 0   |                                                                            |

\* To assimilate the prices given in the table with the present increased value of bones, guano, and all fertilizing materials, it will be necessary to add one-sixth to the value per ton of the manure.

#### ILLUSTRATION OF THE METHOD OF VALUATION DESCRIBED.

A compound lately exposed for sale in the North of Ireland, and described as a Peruvian Guano of superior quality, was founded on examination, to consist of the following ingredients:—

|                                              |        |
|----------------------------------------------|--------|
| Water .. .. .                                | 9.94   |
| Organic matter and ammoniacal salts, .. .. . | 22.16* |
| Alkaline sulphates and chlorides, .. .. .    | 8.65   |
| Phosphates of lime and magnesia, .. .. .     | 16.08  |
| Carbonate of lime, .. .. .                   | 9.23   |
| Earthy matters, .. .. .                      | 39.64  |
|                                              | 100.00 |

\* Capable of yielding 3.5 parts Ammonia.

The valuation of the sample, according to the plan described, will show how far it falls below genuine Peruvian guano, worth from £11 to £12 per ton:—

|                                          |         |      |       |
|------------------------------------------|---------|------|-------|
| Moisture, .. .. .                        | 9.84 x  | £0 0 | £0 0  |
| Organic matters, .. .. .                 | 22.16 x | 0 10 | 11 0  |
| Alkaline sulphates and chlorides .. .. . | 3.95 x  | 1 0  | 3 0   |
| Phosphates of lime and magnesia, .. .. . | 16.08 x | 7 0  | 112 0 |
| Carbonate of lime, .. .. .               | 9.23 x  | 0 5  | 0 0   |
| Earthy matters (red loam), .. .. .       | 39.65 x | 0 0  | 0 0   |
| Ammonia, .. .. .                         | 2.5 x   | 56 0 | 196 0 |

100)3.22 0

20

4.40

Thus taking the proportions of the several constituents, shown by analysis to be contained in the manure, to the farmer, are worth £22, so that the actual value of the manure is only £3 4s., or at present prices £3 14s. 8d. per ton.

#### Analyses of linseed according to Dr. Voelcker:

|                                  |       |
|----------------------------------|-------|
| Water .. .. .                    | 7.50  |
| Oil .. .. .                      | 34.00 |
| Flesh-forming matter .. .. .     | 24.44 |
| Heat-giving constituents .. .. . | 30.73 |
| Inorganic matters (ash) .. .. .  | 3.33  |

One plant of the wild carrot (*Daucus carota*), having 600 flowers, and 2 seeds to each flower, gives 1,200 seeds.

### The Great Sale of Southdowns at Babraham.

On Wednesday, the 18th inst., a goodly company—though not so numerous as that which met about the same time last year—was gathered at Babraham, to witness the last of those sales which for nearly 40 years have been conducted at that place, and during which time Mr. Jonas Webb has carved out for himself, as a breeder of Southdowns, a name which will last as long any records exist of the history of British agriculture.

Among the company there was a large number of distinguished foreigners, some of whom came not merely to see what had been accomplished by the skill, energy, and perseverance of Mr. Webb, but to secure for themselves some of the beautiful and matchless animals that were to be disposed of. Among these we distinguish by way of pre-eminence, the Marquis Perallas, a Spanish nobleman, who fills the post of chairman of the agricultural jury at the International Exhibition, and whose purchases for the Spanish Government amounted to £570, and M. Fischer of Magdenburgh, who purchased to the extent of £676.

Although this was the last of Mr. Jonas Webb's public sales, and he therefore had no

interest in discarding the few comparatively imperfect sheep that will arise in a large flock, there was not one out of the 148 that passed the "ordeal hammer" that would not do credit, independent of the pure blood that flowed in its veins, to any man's stock of store sheep. This we mention, in connection with the fact of these sheep being all yearlings, to account for the somewhat smaller average prices realized as compared with those of last year. Tenant farmers came to bid against lords of title and landlords by profession, and if the former did not feel that they could outbid the latter in one or two instances, they were probably pleased with the beautiful and excellent sheep they secured at very high prices.

At the appointed hour business commenced, but as the space at our command is very limited, we must confine our record of the sales effected to those which reached such a figure as to deserve special notice. We may just mention, however, that lot 63, being the highest priced ram, was secured by Sir T. Lennard for 140 guineas. It will be remembered that at the sale last year Sir Thomas gave the highest price for a pen of ewes. His name, therefore, will ever occupy a distinguished position in connection with the Babraham flock.

Lot 66 made 70 gs., and was bought for the Duke of Richmond; lot 64 was bought for 40 gs., by Mr. Samuel Jonas; lot 67 for 25 gs., by Mr. Cain, Sussex; lot 20 for 91 gs., by Herr Zeopprütz; lot 21 for 72 gs., by H. D. Mildred, Esq., baker, Dorsetshire; lot 25 was bought at 50 gs., for the Duke of Bedford; lot 26, for 40 gs., by Mr. Henry Webb; lot 27, for 30 gs., by Mr. Marris, for Lord Yarmouth; lot 28 (high figures came thick here) for 86 gs., by Professor Nathorst; lot 33 was bought at 27 gs., by Mr. Hart; lot 39, at 54 gs., by Mr. Rigden (Sussex); lot 40, at 40 gs., by Earl Winchelsea; lot 45, at 26 gs., for the Duke of Beaufort; lot 46, at 67 gs., by Herr Fischer; lot 53, at 20 gs., for Lord Chesham; lot 60, at 36 gs., by Mr. Walton; lot 61, at 35 gs., by Monsieur Bonneau; and the last ram before luncheon, lot 62, at 94 gs., by G. S. Foljambre, Esq; lot 68 went at 31 gs., to Herr Fischer; lot 47, at 17 gs., to Mr. Biddell (Playford); lot 80, at 15 gs., to Mr. John Clayden; lot 90, at 25 gs., to Mr. Turner; lot 91, at 25 gs., to Professor Nathorst; lot 92, at 28 gs., to Mr. Samuel Jonas; lot 102, at 55 gs., to Lord Walsingham; lot 103, at 21 gs., to Mr. Manbury; lot 104, at 23 gs., to the Duke of Beaufort; lot 105, at 15 gs., to Mr. James Everett; lot 106, at 15 gs., to Lord Braybrooke; lot 107, at 20 gs., to Lord Walsingham; lot 114, at 21 gs., to Mr. J. C. Taylor (America); lot 126, at 21 gs., to Mr. S. Jonas.

The yearling ewes were very beautiful, and the lots of five, as they were sold, were nicely matched as to color and size; and they excited

quite a smart fire of biddings among the foreigners. The first lot of five offered were sold at 15½ gs., per head, to Herr Fischer; lot 2, at 15 gs., per head, to Mr. Corneille; lot 3, at 13½ gs., ditto, to Professor Nathorst; lot 4, at 11 gs. per head, to Count Chanace; lot 5, at 12½ gs., to Marquis Perallas; lot 6 (only four, one having died), at 15 gs., to Herr Fischer; lot 7, at 10½ gs., to M. Belleras; lot 8, at 14½ gs., to Marquis Perallas; lot 9, at 20½ gs., to Herr Fischer (the highest price given); and lot 15, at 14 gs., to Lord Braybrooke. Only 11 out of 20 lots sold before luncheon were bought for this country, the remaining 19 being for France, Germany, America, and Sweden.

The Marquis Perallas, of Spain, was a large buyer, especially of the ewes.

The following is a summary of the sale:—

|                                |         |   |            |
|--------------------------------|---------|---|------------|
| 148 yearling rams averaged ..  | £19 0 0 | = | £2811 18 0 |
| 289 yearling ewes averaged ..  | 10 1 3  | = | 2908 10 0  |
| 437 yearling sheep averaged .. | 13 1 10 | = | £5720 8 0  |

The summary of last year's sale may be given for comparison sake:—

|                                |          |   |              |
|--------------------------------|----------|---|--------------|
| 109 yearling rams averaged ..  | £24 17 6 | = | £2711 2 0    |
| 199 yearling ewes averaged ..  | 11 2 0   | = | 2209 4 9     |
| 308 yearling sheep averaged .. | 15 19 6  | = | 4920 6 0     |
| 659 (add) older sheep do ..    | 9 2 0    | = | 6006 0 6     |
| 967 sheep (1861) averaged ..   | 11 6 0   | = | 10,916 6 6   |
| 437 sheep (1862) average ..    | 13 1 10  | = | 5720 8 0     |
| 1404 sheep averaged ..         | 11 17 3  | = | £16,646 14 6 |

At the close of the sale hearty cheers were given for Mr. Webb and his family, and the regret was universal that a period has at length been put to the princely hospitalities at Babraham.—*Bell's Messenger*.

## Horticultural.

### Criterion of Fine Vegetables.

The Garden is the most important appendage to the many of the substantial comforts, and some of the most refined luxuries of human sustenance. Its cultivation furnishes a source of health, pleasure and economy, which may be enjoyed by every industrious owner of a few rods of ground, who can devote a little time between his hours of business or labour to this delightful employment. If his occupation and extent of his enclosure will allow him to indulge his taste for fruits and flowers, he may take much pleasure and derive great profit from the management of the vegetable garden alone.

For the purpose of selecting an assortment of the purest vegetables, best suited to the use for which they are grown, we have fixed upon certain qualities which we seek amongst the different kinds:

In the Blood Beet we always look for deep colour, smooth handsome form, small top, and

sweet, tender flesh. In the Orange Carrot, small top, smooth root, and deep orange colour. In the Cabbage, short stump, large compact head, with but few loose leaves. In the Cucumber, straight, handsome form, and dark green colour. In the Lettuce, large close head, pleasant flavour, with the quality of standing the heat, without soon running to seed. In Sweet Corn, long ears, very shrivelled kernels filled over the end of the cob. In the Cantaloup Melon, rough skin, thick, firm flesh, and high flavour. In the Water Melon, thin rind, abundant and well flavoured juice, and bright red core. In the Onion, thick round shape, small neck, deep colour, mild flavour, and good keeping quality. In the Parsnip, small top, long smooth root, rich flavour. In the Pea, low growth, full pods, large and tender peas, rich flavour. In the Scarlet Radish, deep colour, small top, clear root, and quick, free growth. In the Squash, medium size, dry, fine grained, deep coloured flesh. In the Turnips, handsome form, small tops and tap root, sweet crisp flesh.

Those who have never seen better sorts than they possess, suppose they are of the first quality, when they may be very inferior, or almost worthless, when compared with the finest varieties.—*Gardener's Almanac.*

### Moral Effects of a Taste for Flowers.

A correspondent sends us the following extract from an address delivered before the British Association, "on some practical reports derivable from the study of botany :"

"Mr. Ward proceeded to urge the importance of cultivating a taste for legitimate horticultural pursuits among the members of the labouring population, as it was a well established fact that, wherever a pink or a carnation or a rose was seen outside a cottage, there was a potato or a cabbage for the pot within ; that if there was not happiness, there was the nearest approach to it in this world, content :

'Yes, in a poor man's garden grow

Far more than herbs or flowers—

Kind thoughts, contentment, peace of mind,

And joy for weary hours."

And a recent communication from the bishop of Ripon was to this effect : "The parish of Arncliffe, near Skipton, in Yorkshire, situated in a very wild part of the country, and inhabited by a wild and lawless tenantry, had been for many years without a resident clergyman, the living being a very poor one—not above £30 a year. The present incumbent, the Rev. Mr. Boyd, determined, however, to set himself down amongst them, and to use his utmost exertions in bettering their wretched condition. To this end he surrounded his house with a fine garden well stocked with lovely flowers, and induced his peasantry—but with great reluctance—to come in one by one to see and admire his flowers, and

to take them home and cultivate them. Now, for the first time, they had light in their dwellings ; ultimately, through the kind and constant personal care which was bestowed upon them, they have become the most contented and happy set of villagers in all Yorkshire."—*Church of England Magazine.*"

### Domestic.

#### Receipts for Making Various Articles of Food of Indian Corn Meal.

*Corn Meal Pudding.*—Scald four quarts of milk, stir into it one quart of sifted meal, one cup molasses, a teaspoonful of salt, a little spice of any kind you like ; bake it three or four hours in a pretty hot oven.

*Baked Pudding.*—To two quarts of milk, add one quart of meal, a little salt, and a cup of sugar. Prepared by heating the milk over the fire, stirring it occasionally to prevent its burning : when it scarcely boils, remove it, put in the salt and sugar, and scatter in the meal, stirring rapidly to prevent it collecting into lumps ; put in the nutmeg and turn it in a deep pan. Bake immediately, or otherwise as may be convenient, in a hot oven, three hours. When it has baked an hour or more, pour over the pudding one gill or one half pint of milk ; this will soften the crust, and form a delicious whey.

*Boiled Pudding.*—Into two quarts of meal stir three pints of boiling water, some salt, and a gill of molasses or treacle ; spice or not, as you choose. Tie up in a strong cloth or pudding boiler, put into boiling water, and cook over a steady fire for three hours.

*Superior Boiled Pudding.*—To one quart of Indian meal, add three pints of hot milk, half a pint of molasses or treacle, a dessert spoonful of salt, an ounce or more of beef suet shred fine. Stir the materials well together, tie them in a cloth, allow room for the pudding to swell one-eighth larger, and boil it six or eight hours. The longer it boils the better. It may be made without suet.

*Indian Dumplings.*—Into one quart of meal, stir one pint of boiling water, and make them into smooth balls, two or three inches in diameter. Immerse into boiling water, and cook over a slow fire twenty or thirty minutes. If you choose, put a few berries, a peach, or a part of an apple, in the centre of each Dumpling.

*Superior Dumpling.*—To one pint of sour milk with carbonate of soda, add one quart of meal and a large spoonful of flour ; roll out with flour and put in an apple, and cook as before.

*Green Corn Pudding.*—Take eighteen ears of green corn ; split the kernels lengthwise of the ear with a sharp knife, then with a case

knife scrape the corn from the cob, leaving the hulls on the cob; mix it with three or four quarts of rich sweet milk; add four eggs well beaten; two tablespoonfuls of sugar; salt to the taste; bake it three hours. To be eaten hot with butter.

*Homony*.—This article is considered a great delicacy throughout the Southern States, and is seen on almost every breakfast table. It is prepared thus:—The corn must be ground not quite into meal. Let the broken grains be about the size of a pin's head. Then sift the flour from it through a fine hair sieve. Next shake the grains in the sieve, so as to make the hulls or bran rise to the top, when it can be removed by the hand. The grains must then be washed in several waters, and the light particles, which rise to the surface, pour off with the water through the fingers, so as to prevent the escape of the grains. Have a pot or boiler ready on the fire with water in it; add the grains at the rate of one pint to two pints of the water. Boil it briskly about twenty minutes, take off the scum, and occasionally stirring it. When the homony has thoroughly soaked up the water, take the boiler off the fire, cover it, and place it near, or on a less heated part of the fire, and allow it to soak there about ten minutes. It may be eaten with milk, butter, treacle, or sugar. The flour or meal sifted out can be used to make bread or cakes.

*Buck-wheat Cakes*.—This cheap article of food is considered a luxury throughout the American States from the first of October to the first of April. During this period it is found almost everywhere, at breakfast, on the most frugal and the most sumptuous tables. When eaten warm, with butter, sugar, molasses, or treacle, it possesses a flavour that cannot be equalled by the griddle cake whatever. The buck-wheat flour, put up in small casks in Philadelphia, is the best that can be procured in America.

*Recipe*.—Mix the flour with cold water; put in a cup of yeast, and a little salt; set in a warm place over night. If it should be sour in the morning, put in a little carbonate of soda; fry them the same as any griddle cakes. Leave enough of the batter to leaven the next mess. To be eaten with butter, molasses, or sugar.

ELIHU BURRIT.

## The Poultry Yard.

### Fattening Poultry.

From an elaborate and excellent article in the last number of the *Scottish Journal of Agriculture*, we extract the following:—

"There may be said to be three principal modes of fattening, one of which is natural, allowing the fowls a greater or less degree of

liberty, and supplying as much nourishing food as may satisfy their appetite. This method is generally preferred among us, and many experienced poulterers affirm that they can obtain as good fowls in this way, as by any description of forced feeding. In France the prevailing impression is different. The two other methods are artificial; one of them consisting of the forced intermission at certain hours, of paste composed of farinaceous substances; the third, by causing the fowls to swallow by means of a funnel inserted into the mouth, farinaceous substances in a liquid state. This latter method, named *entonnage*, is so simple and rapid that it is thought likely to be generally adopted in preference to any other. The filler or funnel, made of white iron, should be of sufficient size to hold one meal, having a ring below the rim externally, for receiving the forefinger and thumb, and the orifice of the lower extremity cut aslant, the edges surrounded with a thin coating of India rubber, to prevent injury to the walls of the throat. The beverage which by this means is to be introduced, consists of barley meal, (not bruised barley) mixed up without knots in equal parts of milk and water. When all is ready, the fowl is seized by the wings near the shoulder, the head held forward between the knees, and grasped by the left hand, while the right hold the funnel, opens the beak, introduces the instrument into the gullet, and the proper quantity of the mixture is poured in. The quantity of the litter should be about the eighth part of a litre, but only half that quantity is given during the first three days. This dose must be given regularly three times in the four- and twenty hours, at intervals of eight hours. The boxes or frames containing the fowls, should be placed in a stable or other temperate place, protected from the currents of air, and they should be littered with straw, the litter frequently renewed, and every impurity removed. The duration of this treatment is from fifteen to twenty days; if it fails to be successful within that time, the subject should be withdrawn and otherwise disposed of.

"There is one important purpose which appears to us attainable more readily by forced feeding than in any other way, and which has not received the attention which it seems to merit. The great defect of the flesh of poultry as food, is its comparative want of flavour—it is somewhat insipid and tasteless. This deficiency was at once acknowledged, and endeavour to supply by eating along with it ham or tongue. Much therefore would be gained if we could impart to the flesh, otherwise so tender and nutritious, a greater degree of raciness and taste. Artificial feeding seems to present us with the means of accomplishing this; not only indeed, of giving it savor, but even the very degree and kind of flavor which may happen to be preferred. We might thus make game of our chickens, not in the ludicrous, but literal sense of the expres-

sion. We might give them the game flavor; might impart to them to piquancy of flesh found in various kinds of wild birds; and even possibly render it so odorous and fragrant as to surpass them all. The effect that the nature of the food has on the quality of the flesh of animals, is well known. That of the caper-caille has the sent of the fir-shoots on which the bird feeds; hares, inhabiting low wooded regions, have less flavour than such as live on mountains. Domestic rabbits are always insipid when compared to wild ones. Birds feeding on certain berries—those for example, of the juniper—acquire the perfume of their principal food. Such instances might easily be multiplied. They are sufficient to countenance the idea that, by mingling aromatic substances with the farinaceous aliments which form the basis of their food, we could vary at will the flavor of our poultry, when subjected to forced feeding. Substances for this purpose might be derived either from the mineral or vegetable kingdom; from the former cautiously. Flavored berries, such as the juniper, the aromatic buds of trees, the tops of labiate plants, such as thyme, lavender, odoriferous barks, &c., would form materials to work with. They would not require to be used but towards the close of the period of fattening, as a short treatment would be sufficient to perfume, at our wish the whole flesh of the animal. In this way the value of our most common fowls might be equally increased, and they might be brought to equal, and even surpass many kinds of game."

## Veterinary Department.

(Conducted by A. Smith, V. S.)

### Hunters, their Riders, and Breeders.

The majority of our hunting men of the present day will ride (with saddle and bridle) not less than fourteen stone; they are mostly strong, athletic, skillful horsemen, who must and will be carried wherever the hounds go. Need we wonder then, that they have considerable trouble in finding, and have to pay enormous prices for horses that can go and galloping freely, and jumping with such a burden on their backs, field after field, through a strongly enclosed country.

We pay as much or more attention to condition than ever we did. Our hounds are now bread with more speed than formerly. Foxes are frequently rattled into and worried in less than twenty minutes. Our hunters have plenty of speed and blood, but many of them lack that very essential quality in horses, "substance." My tryo will know that the faster the pace in the hunting field the greater will be the danger of accidents, when riding a horse under great weight. But if he must keep pace with the field, he must select a horse with some blood in his

viens; I may almost say that racing blood of the purest kind is essential in these days when fast runs are all the fashion. But where is the class of horse now bred which combines racing speed with substance sufficient to carry a fourteen or fifteen stone man, with perfect safety over a rasping country. The refuse of the racing studs are certainly not the class of animal adapted for a service of this kind; they have been bred solely for their own single quality of speed, they were never intended to carry a *man*—only *baby jockies*. The useful farmer's nag bred in some countries is strong enough to carry an elephant at his own pace, but that pace is not half fast enough for our modern breed of foxhounds and style of riding up to them. We want pure blood combined with great substance, to carry men of average weight with safety and credit. There are many such horses bred, and are to be procured, but the demand for them far exceeds the supply, and it is no uncommon thing for gentlemen to give from two to three hundred guineas for such an animal. Is it not, then, desirable for farmers to turn their attention to the production of such animals. Ours is the best horse breeding country in the world. We have, I am sure, both sires and dams sufficient, with every requisite quality, to form the nucleus of many more breeding studs.

If men can be found to select them, and capital to pay for them, and with judgment and energy to enter into the business with a will and determination to carry it out liberally, I doubt not that a princely fortune would be the result. We have many intelligent and scientific farmers, men who make but few mistakes in breeding cattle and sheep; why do not they pay more attention to the breeding of horses, which would sell as readily, and at more remunerative prices than any other kind of stock. It is as easy to produce a valuable horse as a weedy screw, by paying proper attention to the breed and quality of the progenitors. But many of our farmers breed from worn out mares, and any travelling stallion that happens to pass by the farm, irrespective of all combinations of make, shape, or quality; in many instances both sire and dam may be weak in the lions, touched in the wind, unsound in the hocks, or otherwise afflicted with disease common to most aged horses, and the produce, as may be expected, turns out weak, weedy, undersized foal, with long, bad-shaped legs and feet, like its sire, coarse in its head and general appearance like its dam, without the speed of the former, or the strength of the latter, but almost sure to be afflicted with more or less of the bad qualities of both. This most prevalent error is the cause of farmers paying more attention to the breeding and fattening of cattle, sheep, or pigs, than to the breeding of valuable horses; because after keeping their colts to the age of two, three, or four years, about twenty pounds is considered a fair value for the mongrel bred brutes.

Of all the mistakes and errors committed by small breeding farmers, there is none so prevalent or so fatal as to put a worn-out, halfbred mare to a second-rate, stilty racing stallion, with nothing to recommend him but the empty and worthless consideration of pedigree.

I have seen fine promising-looking colts thrown by old thorough-bred mares when nearly twenty years old, but this is only in the large breeding establishments, where, with rest and great care, the mare has been stronger at twenty years old than at five; this is a far different animal than one who has been worked till she can work no longer, until she is full of diseases and deformities, and then made use of for the reproduction of her species. Like begets its like, and we need not wonder when the breeders who pursue this line of policy are disappointed when the produce is sent to market, and that he gives up the idea of horse breeding in disgust.

Hunters should be bred from mares in the prime of life, while their functions are at their utmost vigour. They should be selected for their power, speed, endurance, and courage, perfectly free from defects, diseases, or deformity; and should be put to short-legged stallions, with deep ribs, powerful quarters, strong loins and shoulders, with sound, well-formed feet, and a smart, intelligent-looking head, well set on. If both the sire and dam be thorough-bred, so much the better; but thorough-bred horses with *substance* are becoming scarcer every year; indeed, how can they be otherwise when foals and yearlings are forced like a hot-house gardener forces his grapes and pine-apples—his owner may get the size and outward semblance, but none of the substance or quality of the fruit when grown in a natural state, and allowed its own time to ripen.

There was a time when children were worked (in the cotton factories of Manchester and its districts) until it was a rarity to see one grown to maturity in the same form that God made him; the result was the notorious transmission of their infirmities to their progeny. Then it was that the legislature interfered, and effectually prevented factory owners from working children until they were qualified to stand the fatigue, without the risk of deformity. I am no advocate for government interference with private enterprise; but I think the time will come when it will be forced, in self-defence, to interfere more seriously in the matter of horse-breeding than it has hitherto done. We have too much of the present quality of racing blood running through the veins of our troopers, which renders them constitutionally weak, and unfit to stand the rigour of a winter at the picket post, especially when existing upon the uncertain supply of forage which is incidental to all armies on a campaign in a strange and perhaps hostile country. The infusion of the racing blood of the present day into the veins of troop horses

also makes them too light for the purpose they are required; a light dragon will, with his kit, ride an average weight of eighteen stone. It is clear, then, that he requires a horse with substance, but it is also essential that troopers should be well-bred; and this class of horse, commonly called the seven-eights bred one, cannot be produced at the price given by government, indeed they cannot be produced at all except through the medium of worn out racing stallions and mongrel-bred mares. But if government could procure a number of brood mares and stallions of the class above recommended to form the nucleus of a breeding establishment, and by these means produce a number of horses and mares with good blood and substance, keeping them solely for breeding purposes, they might then without difficulty produce, by the aid of a cross with a lower, but stronger breed of horses, the finest cavalry horses that ever looked through a bridle.

I cannot but think that a national stake of very heavy amount, say four or five thousand pounds would have a most beneficial effect, no horses to start under five years old, to carry twelve or thirteen stone, a distance of four miles. We all know that notwithstanding the un-natural treatment to which the race-horse is now subjected, that he sometimes attains very fine proportions at six or seven years old. When sent to the stud he thickens, lets down his belly, and as far as regards looks, is quite a different animal to what he appeared during his racing career, and we may have some idea what a magnificent sight would be afforded by a field of such animals, if they were kept and prepared from their very foalhood for this one great event. What is to prevent such a race being established? I am convinced that it only wants starting in the most influential quarters, and the object would be gained; it would give a great impetus to horse-breeding by drawing the attention of capitalists to the subject, and awakening the understanding of those who up to this period breed nothing but weedy mongrels, not worth the litter they lie upon. The money would soon be subscribed by masters of hounds, members of hunts, and the plucky horse-proud gentlemen of our own tight little island, and the sister country, from whence I opine many of the candidates would come.

This great event might be run off at Ascot, —say in six years from the first of January, 1861; it should be open to all nations, and no allowance as to height, weight, or breed, should be made, but no horse should be allowed to start that has ever run in a race previously.

There would be one advantage to the breeding of horses for this event; that, if bred with judgment, the losers, of which there would be a great number, would find a ready market for them at remunerative prices, as animals bred with pretensions to win such an event would be worth

their cost price and a profit, for stud or general purposes; while the refuse of our present breed of racing stock is good for no purpose but to perpetuate their infirmities and constitutional weakness to our mixed breed of horses. Horses bred and reared for such an event as the one recommended are the class we most require for hunters and chargers; for which, I repeat, the demand is far greater than the supply.

In this enterprising country, where capital, soil, climate, and everything tends to encourage horse-breeders, this should not be. People hunt for pleasure; and there can be no pleasure in a fifteen or sixteen stone man riding a weedy animal, only qualified to carry twelve—which we often see in the hunting-field. We have horses sufficient to carry slim undergraduates or dashing cornets; these can be bought in plenty, and at a moderate price; but hunting men of middle age require a dash of pure blood and great substance in their horses before they can "hunt for pleasure." Let us yet hope to see the supply of such horses equal to the demand; but I need not say that this state of things can only be attained by the attention of farmers and breeders being more directed to the first and most essential principles of generation and reproduction, and their conviction that the production of good horses will pay them much better in a pecuniary sense than a mongrel-bred screw.—*Ballinasloe, in the Land.*

## THOROUGH-BRED STOCK FOR SALE

THE Subscriber has for sale DURHAM and GALLOWAY CATTLE, LEICESTER, COTSWOLD, and LINCOLNSHIRE SHEEP, Male and Female 10 Durham and Galloway Bull Calves—price from \$100 to \$200; 20 Shearling Rams, weighing from 230 to 235 lbs. each—Price from \$50 to \$100 each.

JOHN SNELL,

Edmonton P.O., C. W.

Four miles from Brampton Station G.T.R.

## EAST RIDING YORK

### Agricultural Society Fall Show,

AT WELLINGTON HOTEL GROUNDS, MARKHAM VILLAGE, 9th October, 1862.

All Entries to be made by the evening of the 8th, or to be peremptorily excluded.

A. BARKER,  
Secretary.

## THOROUGH BRED STOCK FOR SALE.

THE SUBSCRIBER has for Sale Durham and Galloway Cattle, male and female.

Leicester, Cotswold, Lincolnshire, Down and Cheviot Sheep; Cumberland and Yorkshire improved Pigs. All imported stock.

GEORGE MILLER.

Markham, June 3rd, 1862.

6t.

## THE PROVINCIAL EXHIBITION

OF THE

AGRICULTURAL ASSOCIATION OF UPPER CANADA,

WILL be held at the City of Toronto on the 23rd, 24th, 25th, and 26th September next.

Persons intending to exhibit will please take notice that the entries of articles in the respective classes must be made on or before the undermentioned dates:—

Horses, Cattle, Sheep, Swine, Poultry, on or before Saturday, August 16th.

Grain, Field Roots, and other Farm Products, Agricultural Implements, Machinery, Manufactures generally, Saturday, August 30th.

Horticultural Products, Ladies' Work, the Fine Arts, &c., Saturday, September 13th.

Prize Lists and Blank Forms for making the entries upon may be had of the Secretaries of all Agricultural Societies and Mechanics' Institutes throughout the Province.

HUGH C. THOMSON,

Secretary Board of Agriculture.

Toronto, August 1, 1862.

## GREAT CATALOGUE AUCTION SALE!

OF

Fruit and Ornamental Trees, &c., at Windsor Nurseries.

WILL be sold by Auction without reserve, on TUESDAY, 30th September next, at 10 o'clock, a. m., on the premises, The whole of the immense stock of WINDSOR NURSERIES, consisting of nearly everything in the Nursery line—including the finest stock of Dwarf Pear Trees, Dwarf and Standard Apple Trees, Roses, &c., at the West.

As the Proprietor is discontinuing the business, this will be found a rare chance for Nurserymen, Tree Agents, and Fruit Growers to lay in their stock at unprecedentedly low prices, as everything must be sold at whatever it may bring.

Catalogues will be ready ten days before the Sale, and will be sent with further particulars, on application to the subscriber.

Terms Cash.

JAMES DOUGALL.

Windsor, C. W., 18th Aug., 1862.

## FOR SALE.

A LOT of thorough bred improved Berkshire Pigs of various ages.

R. L. DENISON,

Dover Court.

Toronto, Aug., 1861.

**VETERINARY SURGEON.**

**A**NDREW SMITH, Licentiate of the Edinburgh Veterinary College, and by appointment, Veterinary Surgeon to the Board of Agriculture of Upper Canada, respectfully announces that he has obtained those stables and part of the premises heretofore occupied by John Worthington, Esq., situated corner of Bay and Temperance streets, and which are being fitted up as a *Veterinary Infirmary*.

Medicines for Horses and Cattle always on hand. Horses examined as to soundness, &c.

Veterinary Establishment, Corner of Bay and Temperance Sts.

Toronto, January 22nd, 1862.

Irrigation.

*Editors of the Agriculturist.*—One object I have in writing to you is, to ask you (as you are supposed to know everything, and to be at all times ready to communicate that knowledge to every one), for information on the subject of irrigating grass land. I have about eight or ten acres of land so situated that a creek might be made to flow over it. It is rather heavy clay, and part of it has only 16 or 18 inches of clay till we come to the solid flag, limestone rock. The water in the creek is rather hard, in consequence, I suppose, of running upon the limestone; it is also full of saw-dust from a saw mill on the next lot up the creek. I never saw an irrigated meadow, and as far as my reading extends, it appears to be beneficial only to sandy or loamy soils, when well drained. Now, what I want to know is, would it be beneficial to irrigate such heavy land with such hard water? for I understand that soft water is best. Would the saw-dust be injurious? How near together should the drains be where I could not make them more than 16 or 18 inches deep? Has clay land ever been irrigated with advantage? What work is there published on irrigation and draining combined, that is adapted to Canada? If you could spare space in the *Agriculturist* to answer these questions, perhaps it might be useful to some of your readers, who may have land that could be irrigated, as well as to

Yours, &c.,  
J. W.

Cambray, August, 1862.

REMARKS.

Irrigation has been found from time immemorial to act more beneficially on light, porous soils than on stiff clays, in consequence of the water permeating the lighter soils more freely.

Clay lands, however, have been irrigated with advantage when this operation has been preceded by *under-draining*, which when combined with deep or sub-soil ploughing renders irrigation yet more advantageous. Our correspondent's subsoil being a limestone rock, we presume will readily admit the passage of water through its various interstices; if not, the benefits of irrigation on so shallow a surface soil would be problematical. Impure water is better for irrigation than pure, or rain water. All water found in springs, rivers or lakes is impure; that is, it contains earthy and saline substances in solution. Our correspondent need not therefore be doubtful about his *hard* water, as the hardness is owing to the presence of lime,—carbonate or sulphate,—substances that possess manuring qualities. The saw-dust in the stream would do no harm, unless in too large quantity, when it might interfere with the regular overflow of the water on the surface of the land. It is impossible to give advice about cutting the drains, without knowing how the surface to be irrigated lies, in relation to the stream which supplies the water. They should be deep enough to contain a sufficient quantity of water, and so placed both as to distance and inclination that the fluid can freely and uniformly flow over the whole surface,—Such a surface should therefore be flat, or at least uniformly inclined. If a field inclines different ways it makes it more difficult, sometimes impracticable to irrigate, in a perfect manner. The surface of many of the celebrated

water meadows in Europe, have been carefully prepared by art. Much, however, can be done on uneven surfaces by persons skilled in the practice of the art by what is technically called "catch work." We would advise our correspondent in the first instance to over-flow his land in as thorough and inexpensive manner as possible, and watch the results, of which we should be happy to be informed in due course. We know of no work embracing irrigation with draining that is readily accessible, but we may shortly turn our attention to the subject in the pages of the *Agriculturist*.

Ebs.

### The Grain Aphid.

EDITORS OF THE CANADIAN AGRICULTURIST,—Considering the office of the *Agriculturist* the best repository of facts relating to Agricultural matters in Canada West, I send you the result of my observation and experience of the insect now infesting our grain fields.

I observed it first on a field of oats of my own, last summer. They were early sown, and the damage done to them was small,—the grain was well filled before they appeared, but I had a bushel of Scotch or Fife wheat sown in the same field, late, which was promising well until the oats were cut, and very few insects on it; but immediately after the removal of the oats myriads of these insects attacked the wheat, and when harvested, the wheat only weighed about 45 lbs. per bushel.

They appeared last year to prefer oats to any other kind of grain, my grain bags could scarcely be forced to take in two bushels weight of oats, while the same bags the previous year easily held two and a-half bushels each. I attributed the loss to the insect. This year it commenced much earlier, attacking the leaves of the oats before the grain appeared, and now it takes wheat, oats or barley indiscriminately. There is also a difference in the insect itself this year—last year very few of them had wings,—this year they appear all to get wings in a few days after their appearance, certainly within one week. Some writers compare them to the common house or bed bug, but I see no resemblance between the two creatures in this part of the country, except the general color. The Aphid divested of its limbs, to the naked eye, resembles more the shape and size though not the color of the small or male Flea, also a bed infester.

Yours truly,

A. HAMILTON.

McNab, 16th Aug., 1862.

Fully one-half of the money value of rape and the best cotton seed cakes is obtained back again in the manure.

### Wool and its Prospects.

[The following article we take from the *Michigan Farmer*, and congratulate our contemporary on his re-appearance, after a short cessation, in a much improved form. The two numbers of the new series that have reached us bear evident marks of talent and industry, and the Journal under its improved management, in a splendid agricultural State like Michigan, must or at least ought, to command a large degree of success.—Ebs.]

From a survey, somewhat hasty, or the market, the state of public affairs, and of the other interests that have a bearing upon wool and its value, we incline to the opinion that wool is likely to advance in price than to fall below the extreme rates, that were current during the season of the clip. Why we think so, will be easily understood from the following statement of our reasons.

1. The stock of old wool in the hands of manufacturers and dealers, was far more thoroughly used up than we have known before for several years, at the time when the new clip was ready. The action of the new tariff during the past twelve months had a tendency to set the manufacturers all through the country at work under more favourable circumstances than they have had since 1846; then again, the demands of the Government for supplies for the commissariat of so large an army, with all its wear and tear, had a most important bearing on the consumption of the old stock—and this with an active demand for home consumption stimulated by a remarkable plenty of currency—these causes all serve to use up the stock of old wool. It is gone, therefore, and all that manufacturers can depend upon is this year's clip, a large portion of which, they are not likely to have, for the wool clip of Virginia, Kentucky, Missouri, Tennessee, must necessarily be light, that will seek a northern market, and hence a diminished aggregate supply.

2. The high price of cotton, must have an immense tendency to keep up the price of wool. Already cotton is worth nearly as much as wool, and the supply of cotton becomes lessened more and more, wool must of necessity, in a greater or lesser degree take its place. The demand for a supply of wool is likely to be very great before the next year's clip is ready, and we should not be surprised to note that it had gone up nearly a dollar a pound before first of next June.

3. If the army called into the field by the government consumed as supposed, nearly two-thirds of the wool clip of last year, we certainly have every reason to believe that now, that orders have been issued to double its numbers for the next nine months, the demand for sup-

plies of woolen goods for such an immense body of men, as nearly one million, will of itself create a consumption that will use up all the wool that has been produced in the wool growing states in less than six months, and then!

4. As yet no material change has taken place in the prices of wool in foreign countries, but exchange has advanced so that it is estimated that the high rates are equivalent to an advance in the prices of wool of from eight to ten per cent. But the tariff so discriminates, that our own growers must have a material advantage, while it lasts. We fear, however, that the wants of the country will become so pressing, that all the manufacturing interests will demand a revision or alteration of the duties on the raw material, so that a supply for home demands may be procured at rates that will permit a very great increase in the importation.

The above are the principal reasons we have for the belief, that wool is bound upon an upward trip for the next twelve months, and that we think that it would be perfectly safe for those who have clips on hand, to hold on for a reasonable time, at any rate, as it does seem possible at present, that there can be decline either in the demand or in the prices. Still, it must be borne in mind, that we are at what the people in Washington are pleased facetiously to call "War," and they have been playing at this game in a polite and politic way for the past twelve months. We are not able to predicate what may transpire, should they determine to make war in some other way, than the "make believe" system.

The wool circulars seem to talk very cautiously as to the prices. Walter Brown, of New York, in his August circular, indicates that an advance may be looked for—he says:

"The domestic Wool market during the month of July was extremely active, especially in the wool-growing districts, and the prices still farther advanced—the tendency still being upward. It is the opinion of many, that good wools will soon be worth 60c per pound, in the Eastern markets. The great advance in exchange, the high value of specie as compared with our rapidly increasing paper currency, must necessarily influence the prices of Wool, which is a direct representative of specie. The fact that cotton is selling at unprecedented rates, cannot fail to produce its effect on the Wool market. The new call for additional troops will, in due time, bring new and large orders for clothing. Manufacturers are also already doing a successful business, and under the present tariff, have before them the most brilliant prospects. Every thing seems to force wool into a high range of figures, and yet notwithstanding all these considerations, the future is in reality greatly obscured, and the immense uncertainties of war are oppressing the minds of the people to such an extent, that it may have a very modifying effect on business, and prevent the natural and full

operation of these apparently active causes."

The prices in the New York markets are quoted as follows, and show an advance during the month of 5 to 7 cents:

Choice selected Saxony fleece, 53 a 60c.  
Saxony fleece, 55 a 57c.  
Full-blood Merino fleece, 55 a 56c.  
Half and three quarter blood fleece, 53 a 55c.  
Native and quarter blood fleece, 51 a 52c.  
Common fleece, 50 a 52c.  
Canada fleece, 50 a 55c.

### Breeding and Rearing Pigs.

[A correspondent of the *American Agriculturist* gives the following as his experience in this important branch of farm management. Will not some of our *Canadian* farmers furnish us with *their experience* also? Eds.]

In selecting my breeding hogs I always pick out the best shaped, most thriving boar pig to keep over for a breeder. For a sow I select a healthy shoat, well shaped, but thin and lank, in preference to a fat and sleek one; my reasons for this are, that the lean sow will produce more pigs, and raise them better than one in high order—the sleek one converts all her food into fat and flesh for her own sides and back, while in the lean one it is converted into food for the young. This rule is applicable to all animals. A cow which shows every rib when in milk, will bring forth larger and better calves, and give more and better milk than the one which always looks fat enough for the slaughter. My experience fully sustains my theory. My mode of raising hogs which are intended to be kept over, is to have them pigged about the latter part of August, or first of September, and after allowing them to run with the sow from four to six weeks, confine them in a separate pen. When first taken from the sow they should be fed from six to eight times a day, or else they will fall off in flesh, and it will take them weeks to recruit. Their usual allowance at first should be about a pint of milk to each pig, and in order to facilitate the properly attending to them, the milk barrel should be kept standing very close to the pen, from which it can be dipped with a pail with very little trouble, being replenished night and morning with fresh skimmed milk from the dairy. The quantity of each pig should be gradually increased each day according to the growth of the pigs, until they have attained to the age of three or four months, when a regular allowance should be made them; and the number of times of feeding may be diminished. At this time of the pig's life a little grain fed night and morning, will not be thrown away upon him; a little oats or rye, if the pig is in a healthy condition, followed by a pint of corn, which may be subsequently increased to a quart. This addition of grain will tell amazing-

ly in the growth of the animal, as well as have a tendency to keep him in such a condition that when "fattening time" arrives he will be ready for the knife much sooner than a hog fed only on slops without the daily quota of corn, to say nothing of the saving of a good deal more corn than has been used up to this time in the feeding. The milk from the dairy, when weakened by the slops from the kitchen, should occasionally through the week be enriched by the addition of rye bran.

**Sty and Bedding.**—The pen in which hogs are kept should consist of two apartments—a covered and an uncovered one. An excellent manner in which to construct a pig-sty, is to erect a two-story frame building, having a part of the under story boarded off for a place in which to keep the slop barrel, reserving the rest for a dry pen for the hogs, and have a pen constructed outside, and communicating with this covered one. The feeding trough should be in the outside pen. In this manner, if the pigs are given a sufficiency of rye straw in the inside pen, and the outside one is kept well supplied with the butts of corn stalks, they will not only make an immense amount of manure, but will keep themselves white and clean, thus refuting the assertion of the filthiness which is continually flung at them. In the upper part of this pen should be kept litter for the bedding of these hogs; or a part of it may be partitioned off for a henney.

I have adopted what I consider a very good as well as an economical plan of getting the upper part of my hog building filled with good littering material. It is this: When hauling in my corn fodder I cut off about two feet of the hard dry butts, which the cattle cannot eat, and leave them bound into small bundles and stowed away in the upper portion of the hog house, to be used as required. These corn butts when thrown into the outside pen are so torn and trampled up that they are converted into good lasting manure, which has not its superior on the farm, and which would be almost entirely lost if fed to the cattle in the fields, etc.

**Fattening.**—When fattening time comes, I generally commence by feeding them the "nubbins," and after two or three weeks, follow them with shelled corn. This I always feed boiled, boiling in the morning what is required during the day, and at night what is necessary for the morning. Feeding thus, brings my work nearly all in daylight. In this way I can make my hogs fat enough for all practical purposes, by feeding them from fifteen to twenty bushels of corn, each, and in slaughtering at sixteen months old, they weigh from four to five hundred pounds. I never like them to exceed the latter figure in weight, for I have no fancy for this overgrown and spongy pork of forced hogs.

One plant of the wild parenip (*Pastinaca sativa*) gives the same as the above.

## Cultivating Mixed Varieties of Wheat.

Selected samples of distinct varieties of wheat are now generally cultivated in Scotland. It may be questioned however, if the practice has much to recommend it beyond securing a pure variety for sale or for re-sowing. At one time the wheat usually grown was a mixture of a number of varieties of white wheats, including velvet-eared, and occasionally bearded heads. They are districts in England and on the Continent, where a mixture is still preferred. In some instances in England, red and white wheats are grown mixed, from the belief that the produce of grain is on the whole more uniform, and larger, and the sample brings a higher price in the market, than when either the white or the red variety are grown separately. This is the general result in those localities where the wheat crop is liable to become affected with mildew. With more attention to the cultivation of wheat in Scotland, selection has been carried out, and the greater portion of the wheats in cultivation are true to their kinds. It is therefore important to ascertain whether, by cultivating genuine or unmixed varieties, the produce per acre is not impaired, and as a consequence the money return less, than when a mixture of varieties are grown. Several eminent physiologists state that a mixture of kinds of any of the seed-producing plants usually yield a larger amount of seeds; and this opinion is very general among farmers where the growing of mixtures of the cereals and leguminous plants are carried out. It is supposed physiologists that the different varieties spread their roots at different depths in the soil, and thus draw a larger amount of the constituents of plant life from the soil. Perhaps something is due to the difference of produce in the different varieties, arising from the character of the season, climate, and soil. There are several recorded experiments which support this belief, but more experiments are required to elucidate the question.—*North British Agriculturist*.

## The Atmosphere and the Soil

BY CUTHBERT W. JOHNSON, ESQ., F. R. S.

While the rain pours down upon our fields, as of late, in unusual quantities, our attention becomes more directed to the effect it produces on the soil, and to the good results of drainage. We have, indeed, more than one reason for cultivating such trains of thought: we are ever rewarded, in these studies, by not only the interesting knowledge we acquire, but by the profitable answers which nature so often returns to our inquiries.

It may, then, be practically useful, if, in this wet season, we commune together a little upon these things—if we glance at the origin of our copious rainfalls, and consider how much distant

countries unconsciously contribute, in this way, to each other's welfare—before we proceed to remark the results of some recent valuable observations on the effects produced by the presence of water, and the action of the atmosphere, in drained and undrained soil.

It is, indeed, as a writer in the *North British Review* recently remarks, only the breezes of the encircling air which flows above and around us, that makes the whole world kin. The carbonic acid with which to-day our breathing fills the air, to-morrow seeks its way round the world: the leaves of the date-trees which grow around the Falls of the Nile, will drink it in; it will add to the stature of the cedars of Lebanon; the cocoa-nuts of Tahiti, the palms and bananas of Japan, will change it into flowers. The oxygen we are breathing was distilled for us some time ago by the magnolias of the Susquehanna; and the great trees which skirt the Orinoco, and the Amazon, the giant rhododendrons of the Himalayas, the roses of Cachmere, the cinnamon-trees of Ceylon, the deep forests of Central America contributed to it. The rain we have seen descending so copiously was exhaled for us from the warm surface of the ocean—was thawed for us out of the icebergs which have watched for ages the polar star.

The amount of that rain, in Surrey (where the average fall is about 24 inches; it was only 17.94 inches in 1858, and 22.25 in 1857, was about 20 inches in the last six months of 1859, and has been about 29 inches to December 1, in 1860, as will be seen from the following table, which shows—

THE RAINFALL AT CROYDON, 250 FEET ABOVE THE LEVEL OF THE SEA, IN THE YEARS 1859-60.

|                 | 1859. | 1860.             |
|-----------------|-------|-------------------|

| December .....  | 2.47  | to the 18th. 1.43 |

29.04

With such widely-differing depths of rain, we need hardly add, how very interesting to the farmer is the proportion of these varying amounts of rain-water which his land-drains have to conduct away! This has been carefully determined on different kinds of soil—as on the chalk formation of Hertfordshire, by Mr. Dickson and Mr. Parkes (*Jour. Roy. Ag. Soc.*, vol. v, p. 151; on the limestone formation of Yorkshire, by Mr. C. Charnock, *Ibid.*, vol. x., p. 516); and

on the London Basin clay and the gault, by Mr. J. B. Denton (*Ibid.*, vol. x., p. 273); and, in the course of these valuable observations, both Mr. Parkes and Mr. J. B. Denton had their attention drawn to several curious effects produced by the removal of the land-water on the temperature of the soil.

The rain-fall in Hertfordshire, during eight years, is given by Mr. Parkes in the following table in tons. By this record the farmer will see how much the relative evaporation and filtration of the rain-water varies at different seasons of the year, and, as might be reasonably concluded, its annual amount also; and he will note that, in practice, almost all the filtered portion must either be removed by drainage, or will remain as land-water, dissolving the saline matters, and in several other ways impairing the fertility of the soil:

| April to Sept., incl. |       | Oct. to March, incl. |       |

Of the several injurious effects of leaving the soil soaking in water, the lowering of its temperature must be regarded as one of the chief. The different temperature of a drained and the adjoining undrained soil was ascertained by Mr. Parkes on another kind of land—viz., the deep peat of Chat Moss, in June, 1837 (*Ibid.*, vol. v., p. 141). He ascertained that, although the constant temperature of the *natural bog*, surcharged with water from 12 inches to 30 feet, was 46 deg., and the thermometer planted in the same substance at 7 inches deep constantly indicated 47 deg., yet that in a portion of the same bog, well drained and deeply *stirred*, at a depth of 31 inches, it indicated a maximum temperature of 48½ deg., having gradually gained 2½ deg.; and that in such well-prepared soils the action of the atmosphere is much more considerable and rapid than is commonly believed, is shown by the observation made during the same valuable experiments, that, although the temperature of the natural, unstirred soil at a depth of 7 inches, was only 46 deg., yet that the mean temperature during 36 observations of the *stirred and drained* soil was 10 deg. higher and that after a thunder-storm it rose to 66 deg. The following is the result of their observations:

|           | Temp. of Atmosphere in Shade. | Time of Observation. | Depth below Surface, in inches. |      |      |      |      |
|-----------|-------------------------------|----------------------|---------------------------------|------|------|------|------|
|           |                               |                      | 31                              | 25   | 19   | 13   | 7    |
| June 10.. | 70.0                          | 9 A.M.               | 48.10                           | 48.2 | 50.0 | 53.0 |      |
| 15..      | 60.4                          | 9 A.M.               | 47.25                           | 49.6 | 50.8 | 53.0 | 67.6 |
| 17..      | 67.0                          | 9 A.M.               | 48.0                            | 50.0 | 52.8 | 56.6 | 63.0 |

We have here, as Mr. Parkes observes, satisfactory evidence that the accession of heat was solely derived from meteorological agency—that is from action on the surface, and not from the substratum, as the latter possesses invariably a lower temperature, which must have tended to diminish, rather than to increase, the heat finally acquired by the worked bed.

It is evident, indeed, from these and other observations, that in the month of June rain-water carries down heat, and raises the temperature of of the subsoil; whilst the loss of heat by the strata nearer the surface is quickly restored by the sun's rays. And another important effect is also observable in all soils properly prepared to receive heat and water, and permit their descent—viz., that the transmission of accessions of heat downwards continues during the afternoon of the day, and throughout the night, whilst the superstrata (but chiefly from 7 inches upwards) are losing some amount of their heat by conduction upwards and radiation. Such is the influence of good and deep drainage and ploughing upon the temperature of the soils thus improved. But the benefit does not end there; others follow from those operations—advantages which were thus well described by the late Professor Johnston ("Chem.," p. 110): "Vegetable matter becomes of double value in a soil thus dried and filled with atmospheric air. When soaked in water, their vegetable matter decomposes very slowly, or produces acid compounds more or less unwholesome to the plant, and even exerts injurious chemical reactions upon the earthy and saline constituents of the soil. In the presence of the air, on the contrary, this vegetable compound decomposes rapidly; produces carbonic acid gas in large quantity, as well as other compounds on which the plant can live; and even renders the inorganic constituents of the soil more fitted to enter the roots, and thus to supply more rapidly what the several parts of the plants require."

Let us next refer to the limestone soils of Yorkshire. Here we have on record the observations of Mr. Charnock, of Holmfild, near Ferrybridge, (*Ibid* vol. x., p. 516.) This Journal was kept during the six years from 1842 to 1848. The following table gives a digest of the results obtained in inches:—

|                                                                                     | 1842. | 1843. | 1844. | 1845. | 1846. |
|-------------------------------------------------------------------------------------|-------|-------|-------|-------|-------|
| The total amount of rainfall was.....                                               | 26.11 | 24.49 | 19.0  | 23.18 | 25.24 |
| The evaporation from the soil, when saturated with water was.....                   | 30.02 | 31.19 | 27.85 | 31.09 | 32.28 |
| Ditto when drained....                                                              | 21.55 | 20.11 | 15.40 | 23.26 | 18.30 |
| The filtration from the soil, through a drain three feet from the surface, was..... | 4.55  | 4.28  | 3.60  | 4.92  | 6.70  |

If we examine the clay soil drainage waters, and the effect of their removal from the soil, similar results are obtained.

Mr. J. B. Denton found the temperature of the drained soils, at Hinxworth, at a depth of

18 inches from the surface, was commonly two or three degrees higher than the surrounding atmosphere, and about two degrees higher than that of the undrained soils. One observation of Mr. Denton I have not elsewhere met with. He says, "A remarkable proof of the influence and penetration of atmospheric changes through the soil to the depth of the drains, is seen in the fact that all the outlets discharged an increased quantity of water on the 6th March and 22nd April without any fall of rain on the surface, it being observed on each occasion that a very considerable fall of the barometer had taken place within the previous twenty-four hours."

From the following table constructed by Mr. J. B. Denton, from the results obtained by him in the drainage of the Hinxworth estate of Mr. Catterbuck, several other useful facts may be gleaned. It shows the rainfall in inches, and in gallons per imperial acre, from Oct., 1, 1856, to May 31, 1857, and how many of these gallons of rain water found their way into the drains from the several outlets. In my abridgment of the tables of Mr. Denton I shall give only the quantities of water delivered from two drain outlets, viz., Nos. 6 and 15—the first delivering the water draining from fields composed of the lower chalk, mixed with clay, gravel, sand, mixed with gault; the last, gault clay, with lime infiltrated.

|                                                                    | Rainfall. |          | Discharge from Outlets. |                  |
|--------------------------------------------------------------------|-----------|----------|-------------------------|------------------|
|                                                                    | Inches.   | Gallons. | Gallons. No. 7.         | Gallons. No. 15. |
| October.....                                                       | 1.645     | 37,215   | 12,910                  | —                |
| November.....                                                      | 1.630     | 36,372   | 27,000                  | 503              |
| December.....                                                      | 1.235     | 27,935   | 30,135                  | 5,825            |
| January.....                                                       | 2.333     | 52,775   | 43,885                  | 31,805           |
| February.....                                                      | .192      | 4,345    | 27,300                  | 9,060            |
| March.....                                                         | .820      | 18,547   | 8,415                   | 2,310            |
| April.....                                                         | 1.440     | 32,566   | 6,698                   | 6,183            |
| May.....                                                           | .750      | 16,967   | 4,177                   | 3,418            |
| Total.....                                                         | 10.015    | 227,220  | 163,550                 | 59,931           |
| Difference between the rainfall and the discharge from drains..... |           |          | 66,670                  | 167,289          |
|                                                                    |           |          | 227,220                 | 227,220          |

The mode of draining both the mixed and clay soils of Hinxworth is thus described by Mr. Denton—

"The mixed open soils were drained by occasional and wide parallel drains (from 4 to 8 feet deep), sufficient to discharge the rainfall and relieve the pressure of subterranean water passing through the soil from the higher grounds to their natural outfalls, at a cost varying from £1 10s. to £3 10s. per acre. The drains in this description of soil were reduced to a minimum in number, on the principle that any excess of work beyond that sufficient to remove excess of wetness would be a waste of outlay; whereas in the gault clay soils—which were drained uniformly by a parallel arrangement of drains 25 and 27 feet apart, 4 feet deep, at a cost varying from £5 10s. to £6 10s. per acre—the reverse principle governed the operations, the number of drains being increased to a maximum consistent

with economy; the object being twofold—not only to remove excess of wetness, but to promote an uniform aeration of the mass of clay above the level of the drains, so as to counteract as much as possible its absorbent and retentive nature.

“The total net cost of draining the 800 acres was £3,357 10s, giving an average cost per acre of £4 4s.”

And the reporter had the satisfaction of adding at the close of his valuable paper that the Clay-land Farm had just been let, on terms securing a full return for the capital expended in draining, and other improvements.

The recorded comparative movement of the water in the mixed and the clay soils of Hinxworth are certainly not the least interesting portion of these observations. As might be reasonably expected, Mr. Denton tells us that the discharge from the mixed open soils was much more regular than from the clays. The quantity of water discharged by the comparatively few drains of the freest description of soil during the period of the experiments was 160,920 gallons per acre, out of 227,240 gallons which the rain-gauge showed fell upon every acre drained, while the quantity discharged from the numerous drains of the clays was only 59,936 gallons per acre.

The steady discharge of more than 1,000 gallons per acre per diem from the mixed open soils during the winter—when evaporation is so much less than during the summer—is a fact of considerable importance when considered in relation to the wide extent of similar land requiring drainage. It will be observed, too, that after the autumn rains had completely replenished the absorbent demands of the clays, a large proportion of any succeeding rain was immediately discharged by the under-drains. There was a fall of rain at Hinxworth in October, 1856, of 1.645, and in November of 1.630, equal together to a supply to the soil of 74,087 gallons, or 3.40 tons of water per acre. The drains just began to trickle on the 27th of November, after a fall of half an inch of rain (.540). The test holes in the land showed that the soil was rapidly feeding itself, and that the water-level was rising, but had not reached the level of the drains. On the 12th of December the outlets were running 160 gals. per diem. per acre, after frequent rains in the early part of the month, of less than a tenth of an inch per diem. On the 13th the rain-gauge showed a fall of .452 (nearly half an inch), and the outlets increased their discharge from 160 to 275 gallons per diem per acre. On the 9th of January, 1857, the outlets were running 125 gallons per diem. On the 10th the rain-gauge showed a fall of .542 (rather more than half an inch), and the discharge from the outlets was increased from 125 to 5,150 gallons per diem per acre. How important, adds the reporter, are these facts, in considering the effect

of extended underdrainage on the arterial channels of the country!

The estate of Hinxworth is thus described by Mr. Denton (*Journal Roy. Ag. Soc.*, vol. xx. p. 273)—“It lies at the bottom of the chalk escarpment of the London Basin, and covers a portion of the lower bed of chalk, the out-crop of the green-sand, and a portion of the gault of the green sand formation. In several parts a superficial deposit of drifted gravel and sand overlies the older beds. The green-sand separating the chalk from the gault is very thin, and if collected in a distinct layer, would not exceed three inches in depth in its thickest part. The gault has gained a siliceous character where it comes immediately in contact with the green sand. It has also imbibed a calcareous quality by an infiltration of the chalk through the green-sand into its bed; for a wide breadth, however, the gault is denuded, and there, although the green-sand is absent, a very considerable infiltration of lime has taken place, which I presume may be accounted for by the fact that the chalk escarpment rises in almost cliff-like shape immediately at the margin of the gault, and any submersion of the gault has necessarily imparted to it the character of its more prominent and overwhelming neighbor. The nature of the soil is ever of paramount importance in considering the results of any reported drainage operations.”

The following are the analyses of the soils of Hinxworth by Professor Way :

#### OF THE LOWER CHALK AND MIXED DRIFT.

|                                  |        |

It is from such careful practical observations that the young farmer will derive the most useful information as a guide to his drainage operations. It is not, it is true, the landholders of the light-soil districts of our island that have to

encounter the expense of land drainage. The question is of but very inferior interest to the skilful agriculturists of the Norfolk sands, the Suffolk crag, and of the great southern chalk formation of Surrey, Hants, and Dorset; but it is of great and enduring importance to the farmers of our extensive clay lands.

It will, we may all very easily discern, be long of increasing importance to the cultivators of such retentive soils. It is to them, in fact, that we must now look for that supply of animal food needed to support a rapidly increasing population; and the greater the advances are made in converting such heavy-soil holdings into stock farms, the more desirable it becomes to render their drainage more complete—*Farmer's Magazine*.

- Dundas, at Morrisburgh, Oct. 2, 3.
- Niagara, at Niagara, Oct. 9.

#### TOWNSHIPS.

- Paslinch, at Aberfoyle, Oct. 8th.
- Hamilton Township, at Baltimore, Oct. 9.
- Barton and Glanford, at Ryckman's Corners Oct. 2nd.
- Camden, at Centreville, Oct. 18.
- Vaughan, at Burwick, Oct. 30.
- Norwich, at Otterville, Oct. 11.
- Portland, at Harrowsmith, Oct. 17th.

## The Royal Agricultural Society of Ireland.

The annual Exhibition of this national association was held in Limerick, August 6 and 7; and we are indebted to that excellent journal,—the *Irish Farmers' Gazette* for the following report, which will no doubt interest our readers generally:—

It is just sixteen years since the Royal Agricultural Society of Ireland held its annual Show at Limerick; and when we look back to that period, and open a volume of our journal which contains the record of the proceedings, our thoughts revert to the amazing changes which have taken place in this country since that record was written. The first pressure consequent on the appearance of the disease in the potato had been felt, and unmistakable symptoms were even at that season to be found, shadowing forth the fearful "coming events" which were to follow, though no one, probably, anticipated the full extent of the appalling calamities which actually ensued. Nevertheless, there were those present at the meeting who warned their auditors that a very serious peril hung over the country, and the urgent advice tendered by the writer of the report which appeared in the columns of the *Gazette* was to "employ the people," for "the poor man's crop was gone," gone indeed—"gone with a vengeance;" and those who had the power were assured that to give employment at that juncture would be found profitable to "themselves, the people, and the nation."

This is not the place, nor is it our intention to review the history of our country since the date of the former Royal Show at Limerick; but, occurring as it did just at the commencement of the second chapter of that sad history, it would have been almost impossible to avoid alluding to it, when we are now called upon to record the events which have taken place at the very next meeting of the same society held at the same place. And there are other recollections stirred up when we turn back to the report given in our fifth volume. The place which once knew many of those present at the meeting now knows them no more forever; and though might easily name several to whom this is applicable, we shall content ourselves with merely mentioning two individuals who were then present, whose opinions were listened to with the profoundest respect, and whose memory will be revered so long as British farming can command an historian. We allude to the late Professor Johnston and James Smith of Deanston, both of whom attended the Royal Show in '46, and in whom the agricultural motto, "Science with Practice," was so brilliantly represented. But, on the other hand, we have honoured names still amongst us who were also present at Limerick on the occasion to which we allude, and who took a prominent part in

proceedings; for, amongst the eloquent speakers at the society's council dinners and banquet, we find the names of Sir Robert Kane and of Professor Hodges, the latter as the representative of what was at that time only a promising "yearling"—the Chemico-Agricultural Society of Ulster; but which, thanks to the exertions and eminent scientific attainments of its representative, has long since reached an honoured and useful maturity.

But although space does not allow us to dilate on these and similar topics arising out of reminiscences of the former Limerick Royal Show, it may not be amiss to cast a hurried retrospective glance at some of the winning animals of that day, ere we pass on our description of those of the present time. For it was Mr. Mason Hopper's Belville—one of the best show bulls of of that or any period—with his small and beautiful set on head, his immensely broad back, his remarkably wide chest, and deep, very deep, brisket, which carried off the Purcell Cup and Medal, even as he carried off, in the same year, first prize at the Inverness meeting of the Highland and Agricultural Society, and at the Wakefield Show of the English Royal, crowning all triumphs, four years after, by winning, as the best bull of any age, at the Glasgow show of the Scotch Society, a £70 sweepstakes of silver-plate, which was most appropriately ornamented with his own medal. The Beau of Killerby—then the property of the Hon. A. F. Nugent—was second to Belville in '46; the other winning bulls in the different sections being Lord Dufferin's Daylight, Mr. Christy's King Ben, Mr. Nugent's Eyeglass—of the Bustle by Windle tribe—and Mr. M. Harford's Young Fairfax. In the cow class Mr. Nugent was the leading winner with Elspeth, Modesty—the progenitrix of the late Charleville Gwynne tribe—and Funny Eye, having also his Bundle and her daughter Bandbox commended. Rose de Meaux, which the late Mr. St. George Gray took home when a calf of a few days old from the Foxhall sale in his gig, gave him, amongst others, Louisa by Sir John Sinclair, and that heifer, whose name has since become so familiar, took the first prize for him in the yearling class, and Mr. Christy's very neat Vesper, as another good omen of the future success of the Fort Union short-horns, was commended by the judges of the day, Messrs. Torr, Dudgeon, and Minnett. Lord Riverston was there with his long-horns, whilst the Hon. Barry Yelton enjoyed a walk over with his Herefords. Lord Dufferin's Geordie, and Mr. Andrew Templeton's Miss Elizabeth, took the bull and cow prizes in the Ayrshires to Ballyleidy, and Mr. Seymour, with his Keillor descended polled Angus cattle, cleared all in that class. The winning Blesington Leicesters of modern show were not represented at Limerick in '46, because that well-known flock was not then in existence; but the very flock on which that of Blesington was s. on

afterwards founded—to wit, the flock belonging to the late Mr. Gerge Moore, of Kilbride—won no less than three out of the four prizes awarded to Leicesters; and for the information of those who have been lately reading in the *Gazette* the accounts given by Mr. Wilson and Mr. Gray, of the "Border Leicesters," and the very practical remarks on the same subject which those accounts have elicited from Mr. Thomas Robertson and his friend, Mr. Jones, we may state that Kilbride sheep were essentially Border Leicesters, carefully selected, by John Murray, from some of the very best Tweedside flocks, and, as the show records of that period attest, the Kilbride sheep were always very fortunate winners.

But we now turn from reminiscences of the past—from things as they were in 1846, to things as they are in 1862. And, although we did not find some of the classes, on Wednesday morning, quite so well filled as we have seen them at former shows of our Royal Agricultural Society, we cannot allow it to be said that there was anything like a failure. Several of the short-horn sections, indeed, presented almost a regular catalogue of winners at former shows, and where this was not the case, the entries, for the most part, showed they had come of winning blood; Booth blood of the best sort—thanks to Messrs. Barnes, Chaloner, and Richardson, those steadfast adherents of Warlabey—being a predominant feature. Failure in numbers there might be, but if so, and although we had it all to ourselves—no short-horns having come direct from the other side—still it was more a failure of "weeds" than of quality. Soubadar, Lord John Russell, Sir Colin, Little Wonder, King of Hearts, Victor Emmanuel, Mickey Free, Queen of Beauty 2nd, Rhoda, Evening, Recherche, Lady of Avenel, Pride of Adare, British Queen, Queen of Beauty 3rd, &c., all winners at one time or other, formed in themselves a rare collection of good things, and and much more than sufficient to give a high character to any show in the three kingdoms. We miss, indeed, the Ardferd Abbey "cracks" of the Spring Show, Florentine and Bride of Lammermuir, neither of which were entered for Limerick; and our American Cousin, or speaking according to Coates, the Hero of Thorndale, though also on his own ground, was, in like manner, absent. There were, doubtless, good reasons for the non-appearance or those deservedly high placed animals, but as we do not know what those reasons were we cannot tell our readers, and must rest content with regretting their absence on an occasion when there was such a creditable turn out of the best of the south and south-west.

The flooded fields which met the eye on every hand on the way down afford by no means consolatory prospects of comfort in the show-yards, and certain unpleasant recollections of the Crimean-like mud of Athlone and the incessant

down-pour of the first day of the Belfast Royal naturally arose in one's mind; but we were agreeably disappointed, for although we certainly experienced some very heavy showers, yet the ample shedding of the market place in which the live stock apartment was held, assisted by the nearly as roomy temporary sheds, afforded every possible comfort for the stock as well as of the public, when the latter were compelled to fly for shelter. An efficient local committee, aided by a most zealous and hard-working local secretary, Mr. William Lysaght, had done all that was possible for the accommodation of exhibitors; whilst we need scarcely say that Captain Thornhill was as courteous and obliging as we have ever found him, and Mr. Corrigan, in his capacity as clerk of the yard, just as active as he is when at home in Kildare-street. Of course, the show was honoured with the presence of his Excellency the Lord Lieutenant, who is ever a welcome visitor on such occasions. A large number of the constabulary were also there, chiefly, we dare say, for the purpose of supplying a guard of honour to his Excellency; but it must have looked rather strange in the eyes of English visitors to see fine, stalwart fellows of that force walking sentry, armed with rifles, over sheep pens, short-horned bulls, cocks and hens, and butter firkins; and the sentries themselves seemed to think it all an extremely rich joke, if we may judge from their very good humoured countenances when engaged in that special duty.

The banquet, as is usual on such occasions in Ireland, was numerously attended by many of the principal land-owners and farmers of the country. Notwithstanding the difficulties under which this portion of the United Kingdom at present labours in common with others, a hopeful and encouraging spirit seems to have pervaded the meeting. We make room for the speech of His Excellency the Lord Lieutenant, whose utterances on public occasions are always significant and valuable:—

His Excellency rose amid loud cheers and said—My Lord Clancarty, my lords and gentlemen, I return very sincere thanks to you for the honour you have done me in drinking my health with such kindness. I always feel on these occasions that I had better leave the details connected with the meeting which we are holding to those who must be more competent than myself, from their pursuits and knowledge, to give their weighty authority concerning them. I believe in the show of this year there is very much to approve and applaud, except, indeed, in point of weather (hear, hear). I believe, too, that with respect to the number of cattle exhibited, a county with which I am connected, the county of Yorkshire, may have had some share in diminishing the numbers exhibited on this occa-

sion, the show in that county, which has great attractions for all the north of England, being held in this very week. There can be no doubt that in point of quality there has been a most valuable exhibition of stock, and I believe it will be admitted on all sides that just praise is due to the produce of your dairy farms, and your sheepfolds, too. During all my earlier visits to the meetings of the Royal Agricultural Society of Ireland I have been enabled to use the almost unqualified language of congratulation and hopefulness. Seasons had been favorable, produce had been on the increase, and crime was greatly diminished. The Ireland of the present seems scarcely to be the same as the Ireland of the past, and there were hardly any limits to the glowing anticipations we might form respecting the Ireland of the future. In many points on this occasion I am compelled to take a soberer and more chastened view—especially with reference to one topic, which I cannot omit to mention, but having done which, I will at once dismiss—both because it is the most painful of all, and one which has only an indirect connection with the object of the present meeting. I allude to the reappearance of crime. Old crimes which we had fondly flattered ourselves had been nearly extinguished and well nigh forgotten, have shown their horrid front amongst our rural population. Even the soil of this county has been reddened with blood. Though in this county it has been happily avenged—perhaps “happily” was not the word to use—I will say rightfully avenged—(applause)—this has been brought about, under God, by the fearless and conscientious discharge of their duties by all persons concerned—by council, by judges, by jurors, the magistracy, and by the constabulary. In mentioning the last body, I must take this opportunity to say that I do not think that on all occasions they have been fairly treated. I admit that there may be modifications which it would be right to introduce, and to acknowledge the impossibility of their doing all that some times seems to be required of them—seeing into the inside of rooms at a great distance from them, and receiving information which nobody will give them (laughter); but know as I do how much they daily do and dare for the maintenance of order and for the safety of life, I must consider that some of the attacks which are occasionally levelled against them are scarcely just or generous (hear). I need not point out to you that agrarian crime, if suffered to remain unchecked, would prove a worse enemy to the progress of agriculture even in its strict and narrower sense than either blight, or drought, or rain, or storm, or the worst enmity of the seasons (laughter). Of the enmity of the seasons there has, no doubt, been of late no lack. From the year 1852 to 1858 there have been in Ireland a series of remarkably favourable seasons. Since 1858 we have suffered from a series entirely the reverse. In 1859 we suffered from the

drought. In 1860-61, and up to the sixth August, 1862, we are suffering from deluge (hear). I might call even as a witness into court that broad and noble stream which flows within this town, so formed by nature to adorn, defend, and enrich the district which it waters, but which of late years has certainly given somewhat of an overplus of its wealth of moisture (hear). Now, these fluctuations of the seasons we have always been liable to in Ireland, and always, I fear, must be. They are mainly owing to the geographical position of the country, which we cannot hope to shift or change (laughter). I am aware that fault has been found with me once and again for dwelling upon the superior adaptation of the country to purposes of pasture and the rearing of cattle, and so seeming by implication to discourage tillage and the growth of crops. Now, no one could refuse to give tillage and the growth of crops their proper opportunity and their proper sphere; but surely, it is the part of a prudent man to take things as they are, and to follow the indisputable law of nature (hear). It is undoubtedly true that for a late season or two there has been a material falling off in what may be termed the general agricultural income of the country; but it is as true, and can be proved from authentic documents, that this decrease has fallen upon tillage and crops, whereas the value of stock has actually increased. I am sure you will excuse me for pointing your attention to this subject, which does seem to me entitled to your most serious attention; and it appears to me to establish in controvertably that in Ireland stock is the most steady and permanent part of rural income (cheers). I think we should be quite wrong to consider that the increase of cattle necessarily leads to the decrease of tillage. Modern husbandry has introduced stall feeding—stall-feeding increases manure, which is the surest staple of tillage (hear); and I believe it to be true, notwithstanding the decrease for the last few years in the value of crops, still, that all the processes and methods of agriculture in Ireland are exhibiting continued improvement (hear). Much capital has been devoted to drainage, and whether we consider the character of the crops, the soil, or the climate, there is no doubt that agricultural speculation could not take a more beneficial direction. The late report of the Commissioners of Public Works shows that in Ireland on 200,000 acres thorough draining, in a great part subsoiling, have been carried into successful operation since 1848. The amount expended in the last few years was, in 1859, £30,000; in 1860, £32,000; in 1861, £36,000; and in the first half of the present year, £32,000. In the County of Limerick alone the gross expenditure contemplated and in progress under the last improvements has been £188,000, of which £9,000 has been for labourers' dwellings. This quota is above the average of the other Irish counties, and is always exceeded by Cork

and Kerry. Now, this process of drainage naturally gives room for the introduction of improved implements, such as we saw with pleasure at the show-yard to-day, by which, being enabled to conduct all the operations of agriculture more rapidly, we may render ourselves less dependant on climate or weather, or in the literal words of the old proverb, we may thus be enabled to "make hay when the sun shines" (cheers). I am aware to what disadvantage the cutting of hay and corn and the stacking of turf must be exposed in some of the rainy seasons with which we are so often visited, but I cannot help thinking that by a more vigilant and determined attention to such opportunities as present themselves, even in the most outward seasons, a great deal of that which is now lost might be made comparatively safe (cheers). I have admitted then, that there is certainly something of gloom in the circumstances which have of late surrounded us, but I feel sure that every lesson borrowed both from the past, the present, and the future warns us against giving way to despondency (hear, hear). Even now in many crops, and in many districts, there are manifest signs of progress and improvement (applause). I earnestly trust that fine autumn may give us a turning point in the character of the late seasons. There are some though I cannot pretend to dive into their mysteries, who, from magnetic and electrical objections, feel justified in assuming that they will be able to ascertain more accurately those general laws which regulate the character of the seasons and of the weather; but I trust that in any case the agriculturists of Ireland will profit by experience in the same way in which they so largely did after the disastrous period which intervened from 1845 to 1849. In the remarks which I have thus taken the liberty to address you, I have mainly confined myself, as I was bound to do, to the topics and prospects of Irish agriculture, but both within and without their range there has been of late no lack of disturbing causes. Europe, Asia, and, above all, America, have heaved and are heaving with convulsions. We have sustained one famine in Ireland; we are now suffering in some degree, though in a very mitigated degree, from deficient harvests. The wealthiest district of England seems now all but paralysed by the sudden withdrawal of its most vital element. The commerce of the world has altered his laws and its actions. Steam and railways have changed the whole condition of transmit. Such changes, so extensive—such shocks, so violent—defy all calculation; but they should not shake our confidence in Him who gives the sunshine as well as the storm, the fertilizing rain as well as the drought, manna, the milk and the honey, as well as the stony rock and the sandy desert—who from evil bringeth good, and in judgment remembers mercy (applause.)

### Yorkshire Agricultural Society.

The recent annual show of this renowned Society, held in the city of York, appears to have been attended by its usual success. The subjoined report, from the *Mark Lane Express*, will be found to contain much interesting information to our readers:

It was on the Wednesday that the short-horns—the very aristocrats of a Yorkshire show—riveted the gaze of their many admirers; and yet, so far as mere numbers went, there was no formidable array here. In fact, the very entries read rather like “running-off ties” than the original composition of open classes. And this was the general character of the York show of short-horns. It was running-off ties. In no class were the entries great, but nearly all the animals were amongst the very best of their breed, and the majority of them as well known as winners. Mr. Stratton, who acted with Mr. Drury and Mr. Thomson of Anlanby, told us it reminded him of his first visit to a York show, some twenty years since, when he saw Bracelet, and Necklace, and Duchess 34th, and Buttercup in the ring, with that famous bull, the Duke of Northumberland, to open the lists. But there were as famous bulls in the yard on Wednesday; and it is long since so generally good a class has been got together:—Royal Butterfly, a winner of the Royal at Canterbury, and of the Yorkshire at Pontefract—Skyrocket, Feversham's grand Leeds bull—a rare, deep great bull from Scotland called Van Tromp, and Victor Emmanuel, also from over the border, and both destined to earn distinction to-day. Then Mr. Robinson sent on his new purchase, the 2nd Duke of Airdrie, the first Duke in Essex, and with some notice even in Yorkshire. The neat Master Buttercup was to be named only in the next degree; and Mr. Wiley's white Sir Charles, with two or three more, completed a class out of which the judges soon selected those they ultimately named for either honours or notice. Their ultimate choice, Royal Butterfly, has worn wonderfully well, and walked away as light and airy and handsome as ever. He does not look near so big as he did at Canterbury, but is a blood-like animal, with nothing coarse or patchy about him. Never was a prize more fairly won; for Skyrocket, sadly disfigured with a large swelling on one of his knees, has visibly wasted, and only still preserves his fine noble outline. There were many fancied Mr. Home's bull would beat him, a long way as he was before the other two commendations. As it is, Van Tromp may succeed to a place, for Butterfly was objected to as having been first at Pontefract, where the Yorkshire meeting was held two years since; and it is even

said that Skyrocket may be disqualified from his having won at an associated show of the Yorkshire and another society, as held at Leeds last summer. Only half a dozen two-year-olds came into the ring, of which the Battersea Gamester was clearly the best, although with a bad rash disfiguring his clean white skin. Mr. Stratton had it more his own way for second with a wealthy beefy bull, but with little of the style or show of Master Frederick, whose beautiful wild, roving eye told immensely against the dull, sleepy expression of his rival. Mr. Fawkes' bull was deservedly commended; and then, over the yearlings, the Battersea awards became more bothered than ever. The *third* in London was the *first* at York; the *first* in London was the *second* at York; and the *second* in London was the *third* at York. But there is no doubt Whipper-in's travels have told on him, for we never saw him show so badly, and people were more inclined than ever to pull him to pieces “behind his back.” It will need all Mr. Tallant's talents, and they are of no common order, to get him in form for the sale, which is to be really genuine, and everything to go for what it will bring. Windsor Augustus, on the contrary, was very even and well covered, and the tenth Butterfly true in his points and fresh in his looks. The awards spoke well for Mr. Carr's herd, who not only bred the best of them, but had a yearling in his own name most deservedly commended. Standing very deep on a short leg, and with a capital twist, a certain thickness of horn rather detracted from Don Windsor's appearance; but even this is something of a warranty for masculine character. The easiest thing of the whole day's work was Mr. Robinson's clever calf placing himself over a rather middling class, with Lady Pigot's alone to be numbered anywhere near to him. Jericho, who has gone on well since Battersea, was sold at York previous to the award for a hundred to the Baron Nathusius, who takes him out to Prussia.

The short-horn cows and heifers were, if anything, more select. In the two senior lots of aged and three-year-olds with only five in each class, there were Mr. Eastwood's Rosette, Mr. Douglas's Maid of Athelstane, Mr. Booth's Queen of the Vale, Colonel Townley's Rose of Lancashire, Lord Feversham's Valetta, Mr. Booth's Queen of the Ocean, Lady Pigot's Pride of Southwick, Mr. Mitchell's Mistletoe, and Colonel Townley's Young Butterfly—nearly every one fit to be first. The judges, in fact, specially mentioned nine out of the ten, while they generally commended the classes of two-year-old and yearling heifers, with ten in the one and eleven in the other. It was thought that the London gold medal cow might have been down calving at Warla-

by; but Queen of the Ocean never looked better, and we are quite willing to admit that we liked her a deal more in York than in London. Rosette is getting coarse and vulgar behind, and Mistletoe has the same very visible failing; but the other cows were all wearing well and in a capital show condition; while amongst the younger heifers Mr. Douglas got the Queen placed to his liking at last. She has been beaten, however, again since Battersea, at Belford, by Mr. Wood's Bonny Belle, a very neat one, only commended by the Royal, and highly commended here; so that out of the three trials the Athelstane beauty has *just* the best of it. The latter, from the way she has been made up, threatens soon to become cowy, but for compactness of frame and fine points she is *now* certainly very admirable. Her second here was a wonderfully useful white of Mr. Atkinson's, only a little deficient in quality, while Lord Feversham's Cecilia, the Royal third, Lady Pigot's Victoria, and Roan Knight's Butterfly were included in the general compliment paid to the class. In the next, about the only mistake of the day occurred, where Lady Pigot's handsome Rosedale was outplaced for second by one of Mr. Singleton's, for some reason, which to the mere lookers-on was more or less inexplicable, and that almost warranted the bit of temper shown by her ladyship's herdsman when he indignantly threw away his high commendation. There was but a small lot of calves where Frederick's Farewell, wrongly entered amongst the older heifers, rather annoyingly for her competitors, was suffered to show in her proper place.

The following succinct and admirable rules, as published in the catalogue, are worthy of the attention of similar societies: "When the cows and heifers are certified to be in calf, the prizes awarded will not be paid until a certificate of their having had a live calf has been delivered to the secretary. The heifers in class 7 shall be certified to be one month past their bulling. The number of five calves that cows have had shall be certified. The bulls in class 1 shall be certified (at the time of entry) to be sires of live calves; and in classes 2 and 3, that cows are holding to them. In awarding these prizes, the judges will be instructed not to take into consideration the value to the butcher of the animals exhibited, but to decide according to their relative merits for the purpose of breeding." With the first of these conditions, by way of a warning, the Empress of Hindostan, though entered amongst the breeding cows was not sent. Surely this is a lesson of itself to such associations as the Northampton, where this fat beast took a prize.

At the dinner (H. S. Thompson, Esq., president of the society, in the chair),

In the course of the evening the chairman gave "Success to the Yorkshire Agricultural Society." This society had now been established since 1837. It was in this month in 1837 when the society first met in York for the purpose of organizing a Yorkshire Agricultural Society. Since that time, of the Council, which consisted of twenty-eight members, sixteen had died, and there were twelve remaining, and out of these twelve eight were still on the council, thus showing that the earlier promoters and supporters of this society had continued to give their support so long as health and strength would allow them. The society had existed for twenty-five years—a quarter of a century—and it would be interesting briefly to review their proceedings, and see what, in that time, they had really accomplished. Before saying what they had accomplished, he might say a few words on what they had not accomplished. They were young and enthusiastic as farmers when they formed that society. In the course of that time they had endeavoured to promote agricultural improvement in every form, but one of the things they had not been able to do, they expected they should have been able to do, was to raise the standard of produce either in the way of stock or crops. He had been a constant attender at the meetings of this society and others, and *he must give it as his unhesitating opinion that they had not raised their standard of perfection in the best animals or best crops beyond what they could do twenty five years ago*. He did not wish to be misunderstood. He would say unhesitatingly that the prize animals shown by Earl Spencer, the Booths, Mr. Bates, and others, were as good animals as were shown now by Mr. Booth, Mr. Fawkes, and others. He thought the prize animals were quite as good then as they are now. Well, then in reference to the crops. It was very common to grow five quarters an acre, and it was not unusual to grow six; and what more could be done at this day? If more was grown by any one, he hoped they would come and ask him to see it. He believed they had not raised their standard at all, either in cattle or crops, beyond those days, but they expected to do a great deal in that way. They had a little smattering of agricultural chemistry, and they thought if they knew the land was too rich down went the crop and injured the quality and quantity, and that they would be able to find out what to administer to grow large crops to the acre. What had they done to increase the produce per acre in roots on the best farms and in the best seasons? <sup>see</sup> He had a great friend he often used to go see, who told him he could grow 100 tons of swedes to the acre. He was afraid he was rather incredulous. His friend showed him

some very fine turnips, and he found some that would weigh a stone. It was quite true that it was so. He (the chairman) should say that on the average they would weigh eight or nine pounds; and he said at the time, "What as to the 100 tons per acre?" His friend said it was very easy to make out that there were 22,000 plants to the acre, and if they only weight seven pounds, that made seventy tons to the acre; and if they could only get an average of ten pounds, that was 100 tons to the acre. It seemed very easy, in that way. He asked his friend when he had got one hundred tons per acre if he would be kind enough to let him know. His friend afterwards said it was not that year, the fly had been so bad; another year he said the wire-worm had been destroying them; and a third year he said, owing to the confounded seedsmen, they could not come up well. His friend lived to a good old age, and without growing his 100 tons, or 50. He could not see they were able to grow more to the acre on highly farmed land in a good season than they did then. Had they done nothing? So far from that, he should say it had been proved by facts that there had been no period since the beginning of the world in which such real gradual agricultural improvements had been realized as within the last quarter of a century. They had not increased the maximum, but they had the average very much indeed. Good stock was much more diffused than it was, and it was much more rare to see bad stock. How had these very great improvements been effected? Very much by the change effected in our means of cultivation, and greatly to the improved intelligence of the farmers. During the period to which he had alluded, the whole machinery of the farms had been changed. When they first framed their prizes for this society, they were anxious to make them such as would promote agricultural improvement. What did they offer for the different classes of things? He was surprised to find that they offered £424 for stock, £80 for written reports, about £60 or £70 for miscellaneous things, and for implements, £30. Out of £600 they offered in prizes, £30 were offered for implements. That showed the appreciation of the comparative importance of stock and implements. This year they had offered £250 for implements, and the increase in the number exhibited had far exceeded the proportion of £250 to £30. They had seen the rise of steam machinery altogether. The first steam thrashing machine ever exhibited was at Hull, in 1841. It was the fourth show they held, and many people on that occasion were very careful how they went near that machine, as they thought it was dangerous to be in the hands of farmers. There was a great number

of smocky engines now in their show yard, and the wish was now to get near them whilst at work. Steam thrashing machines, he was happy to say, were now more common than horse thrashing machines. Look at the steam plough. Many present, no doubt had an opportunity of seeing the steam plough at work within the last few days. What was its position at the present moment? He should say the problem of the successful effectual cultivation of the land was solved. They could effectually cultivate the land by steam machinery. As to the question of economy, he thought the cost of the most economic application of that power to this purpose was making rapid progress. Year by year the expense of it, the wear and tear, and other expenses attending the application of steam power was being reduced, and in a few years it appeared likely that steam ploughs would be as common as steam thrashing machines. He did not say that steam ploughing was now in such a position as to render it advisable for farmers to introduce it upon their farms. Land, however, could effectually be ploughed by steam, and in a few years he thought it could economically as well as effectually be cultivated by steam. He felt it was only fair to ask who were the men who brought it to its present position. Steam ploughs did not make themselves, and they ought not to turn their backs on the men who had fought the battles, and brought the question to its present position. The two men who had borne the burnt of the battle were Messrs. Fowler & Smith. In proposing the toasts, he should beg leave to ask the company to drink their healths, and he would now say publicly that he thought they were exceedingly indebted to them. After referring to their perseverance, the chairman said he was happy to tell them that the manufacturers of Mr. Fowler's plough had, since the 1st of January, sent out forty-five complete sets of engines and apparatus, the great majority of which were in the hands of Englishmen. He would next allude to the importance of covering farmyards. He had tried it himself, and having found its great value, he had made one for a tenant at his express request. The greatly improved value of the manure was such, that whoever tried it would never be without it in future, and he felt perfectly satisfied it would improve the means of fertilizing the land fully twenty-five per cent. The cost was scarcely appreciable when they were making farmsteads, but if they had it to do entirely new it would cost about 5s. per square yard. His toast was "Success to the Yorkshire Agricultural Society." They had achieved, he thought, a considerable measure of success, and he thought a set of Englishmen never had a good cause in hand they did not make

answer. The cause they had in hand was one which was worthy the attention and the exertions of Englishmen, for it was no less than that of providing food and employment for the whole nation.

### Professor Cameron's Lecture.

The following is an abridged report from the *Leicester Express* of Dr. Cameron's interesting lecture which he delivered before the County, Kildare Agricultural Society, in Naas Town Hall, on the 29th of July last :

The lecturer commenced with a few introductory observations, in which he complimented the society on the prominent position which they occupied amongst the agricultural societies, and congratulated them on the important results which had attended their recent efforts to extinguish the sale of spurious and inferior manures in the county. He next defined the three great divisions into which all the objects of external nature were arranged—namely the mineral, the vegetable, and the animal kingdom. There are many thousands of bodies, possessing different properties, each distinguished by its attributes from all the others ; yet by the process of chemical analysis all these substances are resolvable into about 66 elementary or simple bodies—kinds of matter which cannot be resolved into simple forms ; that is, cannot be decomposed. Of these 66 bodies, one-half occur in very minute quantities ; and their functions in the economy of nature are totally unknown. Of the remaining elements a large proportion occurs in but comparatively small quantities, so that, after all, but little more than a dozen raw materials are employed by nature in building up its rich and varied products. The functions of plants were next described. These, said the lecturer, should be regarded as stationary mechanisms, designed by the Creator for the elaboration of lifeless mineral matter into organized structures, capable as being used as food for animals. Plants grow only when exposed to the influence of light and heat, and the various other subtle forces which reside, so to speak, in the sunbeam. These forces are expended during the growth of the plant, and in fact, the development of the vegetable substance is in an inverse ratio to their disappearance. Plants are, therefore not merely stores of organized matter, but also magazines of force. During their decomposition, or the reconversion of their elements into a mineral state, all the force (heat, light, &c.) expended on their production is again set free. It has been proved beyond doubt that matter is indestructible. It is also certain that force or motion is equally unannihilable. We may alter in a thousand ways the form of matter, but its weight cannot be

reduced. We may alter the nature of motion—we can convert magnetism into electricity, electricity into light, light into heat, and heat into motive power, but we cannot utterly destroy any one of these forces. Animals require food in order that they may be enabled to carry on those motions which chiefly constitute vitality. The animal is perfectly unable to organize mineral matter, the substances by which its body is repaired must be but little different in nature from the body itself. Chemical analysis has shown that there is scarcely any difference between those parts of plants consumed as food and the animal body ; so that the latter merely reorganizes the vegetable albumen into animal albumen, and the vegetable fat into animal fat. The constituents of food admit of arrangement into three classes—The nitrogenous, non-nitrogenous, and mineral. The nitrogenous substances are formed of oxygen, hydrogen, carbon, and nitrogen, with minute quantities of sulphur and phosphorus. They alone are employed in the production of lean flesh, or muscle, and the organic or combustible portion of the bones. Hence they are termed flesh-formers. The white of eggs, the curd of milk, the gluten of flour are flesh-formers. The non nitrogenous substances are formed of carbon, hydrogen, and (sometimes) oxygen. They embrace starch, sugar, oil, and the production of heat, and hence are termed heat-givers. The mineral matter is used principally in forming the bones. The lecturer here entered at great length into the subject of the origin of animal heat and motive power, and demonstrated that the greater part of the food taken was consumed in carrying on the processes which give rise to their development. The native of the Polar regions is obliged to use an enormous quantity of fatty food to maintain the temperature of his body, at 100 and even 140 degs. higher than of the air surrounding him. The native of the East Indies, for an opposite reason, uses but little food, and that of a watery kind, the evaporation of the fluid portion of which from his body keeps him cool. Thus, on the one hand, by the process of internal heating and on the other by internal refrigeration, the temperature of the body is maintained at the same point—nearly 100 degs. Fah. Whether the individual be at the tropics or at Nova Zembla, the laws which govern the life of man control with but slight modification that of his "subjects in creation." Animals use food in order to make up for the waste which their bodies are continuously undergoing, and also to maintain the heat which is essential to their healthy vitality. An animal in a constant state of activity will consume more food than another which is in one of quiescence. In cold weather an animal if exposed, will require a larger supply of heat-giving food than it will if kept in a warm place. A beast undergoing the fattening process should be placed in a darkened situation, allowed to be

perfectly quiet, and kept at as high a temperature as is compatible with its health. Under such circumstances the flesh stored by it will cost the feeder far less than if the conditions were of an opposite nature. That by far the greater portion of the animal's food is consumed in developing heat and motion is evident from the fact that an ox will eat  $1\frac{1}{2}$  cwt. of turnips and 5 lbs. or 6 lbs. of oil-cake per diem, and still will only increase in weight by a couple of pounds. The feeder will find it more economical to keep the animal warm, by burning cheap coal *outside* its body, than by burning costly oil or starch *within* it. The best kinds of beasts for fattening (though not for breeding from) are those with large lungs—narrow chested. In such animals, the respiratory process is feebly carried on, and the amount of matter consumed in producing heat is comparatively small. Neither playful or irritable animals should be selected; the quieter—in fact, the more stupid—the animal the greater is its tendency to fatness. The presence of several stout persons prevented him (the lecturer) from applying this principle to the superior animal—man. The food should be adapted to the age of the animal. Calves, and the young of every kind of animal, should be abundantly fed with assimilable food, which should also be highly nitrogenous. During the formation of the bones, the hide, and the hair, much nitrogen is required, because these parts contain a large proportion of that element, and but little fat. When the animal is fattening, it should also be supplied with easily digestible food, in which the fatty and starchy constituents preponderate. It was a mistake to suppose that even in these animals the lean predominated over the fat. The recent researches of Laws and Gilbert prove that in the carcase of a lean sheep there is 50 per cent. more fat than lean; in a fat sheep the proportion of fat to lean is as 4 to 1; the carcase of a moderately fat pig contains five times as much fat as lean. It would thus appear that the more fat-forming substances which the food of store animals contains the more valuable it is. In all probability a large proportion of the nitrogenous constituents of oil-cake and bean meal is passed through the animal's body unchanged, the oily matters being alone completely assimilated. In the early stages of fattening, coarse food, containing a large proportion of woody fibre, may be given, and the greater portion of it will be assimilated; but in the last stage of the process, only the most nutritious and easily digestible aliments should be given; for the tendency to the secretion of fat being then at a minimum, and the appetite of the animal being much impaired, it will only consume as much food as will enable it to discharge the necessary functions of life. If, however, the nutriment be of a very tempting kind, it will probably eat in excess, which will contribute to the increase of the animal's weight.

It is by careful attention to such points as these that the finishing of beasts for the butcher can only be economically accomplished. The half fattening of animals is easily enough effected; but the difficulties in the way of fully completing the process appear to be very great; for in Ireland it is seldom profitably accomplished. Perhaps, when the knowledge of the scientific principles upon which the economic feeding of stock depends is more widely diffused this state of things will be improved. The chemical composition of aliments is not alone to be depended upon as a complete indicator of their feeding value. At one time the value of a food substance was estimated by its amount of nitrogen; but that was a mistake. Many kinds of food, more especially young succulent plants, contain large proportions of their nitrogen in an almost mineral state—at all events, in a form not sufficiently organic to admit of its being assimilated by animals. Many substances, to which, according to analysis, possess a high feeding value are practically inferior to other substances of lower analytical value. Rape-cake contains far more nutritive matter than linseed cake; yet no feeder prefers the former to the latter. The causes of the inferiority of such substances as rape-cake and their remedy are important problems, the solution of which would be of great advantage to the farmer. Some of the causes are already known. For example, rape-cake contains in very small proportion a disagreeably flavoured substance, which causes animals to dislike it. By steaming the cake and adding a little molasses or other sweet or flavoured substance to it, the disagreeable flavour is removed, and even fattening animals will readily eat it when it is presented to them in this state. The addition of an equal weight of locust beans (dried and crushed) to rape-cake so completely disguises the strong flavour of the latter, that stock will not only eat it, but, what is of far more importance, thrive upon it. Dr. Cameron next dwelt at considerable length upon the necessity of attending to the mechanical constitution of the food. A great deal of the motive power of the horse is needlessly expended in the process of grinding his oats and hay. If a man were obliged after a hard day's toil to use his teeth in grinding all the hard grains of wheat required to make a loaf of bread, he would find the process anything but delightful or refreshing. There is no occasion to cook such soft food as turnips and mangels; but inferior, hard, washed out hay and other rubbishy kinds of food are best made use of in a chopped and cooked or fermented state. Such food should only be given to working animals or lean beasts. After expatiating for some time on the importance of the subject of his lecture, and suggesting to his hearers the carrying out of certain feeding experiments, the learned Doctor brought his lecture (which was delivered extemporaneously and

occupied nearly two hours to a close, amid warm applause. The Doctor having stated his willingness to answer questions, several were put to him by the chairman and others, and were satisfactorily replied to.

## Horticultural.

### Cultivation of Window Plants.

The cultivation of flowers in the windows of dwelling houses has been for years rapidly extending in European countries, and it is a source of pure domestic pleasure and rational improvement. In Canada the principal objection urged against the raising of plants in windows is the liability of their being frozen during the intense cold nights, which are certain to occur now and then during winter. This evil, however, can be avoided, or at least greatly mitigated by a little extra care and attention, and we are glad to find that flowers in windows are every year increasing. The following report, condensed from that excellent periodical, the *Gardener's Monthly*, of a recent meeting of the *Pennsylvania Horticultural Society* held in Philadelphia, will be found suggestive:—

Dr. Jack read an essay, detailing his experience in growing window plants, and setting forth his method, which has been quite successful. He said that the subject was one of interest to all who have a love for plants, and especially to those who have not the conveniences for greater indulgence.

The conditions most desired, and the attainment of which has proved the most difficult, are the application of an even heat, and the maintenance of a constant moisture. In order to protect his window plants from an atmosphere too dry, he has pursued the plan of enclosing a space inside of the windows, projecting a case into the room and giving it the form of a bay-window. This is indeed but a Wardian case, one side of which is composed of entire sash. The dimensions are, height, 5 feet 8 inches; width three feet seven inches (this being the size of the window frame), and depth two feet eight inches.

The accommodation of the plants is effected by a circular stage of 31 inches in diameter, revolving on a central stud. This form of stage permits a variety of arrangement, and allows access to all parts for the purpose of watering, etc. While this form of stage retains the moisture constantly rising from the soil

equally as well as the ordinary Wardian case, it is better supplied with light, and affords an opportunity for a much more tasteful display of plants. It is liable to great diminution of external air, by which means, in cold weather, the plants suffer for heat.

To secure a uniform and sufficient temperature, an opening is made on the top of the case for the entrance of warm air, and another in the bottom, for the exit of the cool, which falls in consequence of its greater specific gravity. By this means, the plants are perfectly protected from contact with cold air. The current of warm air entering the top would, however, naturally dissipate the necessary moisture. To avoid this, a net work of loose cotton thread is placed over the opening, one end being immersed in water. Capillary attraction causes the whole to be moistened, and the air, in passing over it, becomes saturated with water.

The effect of this method is shown in the better appearance of the plants, a greater evenness of temperature, and the constant marked presence of humidity. All this is accomplished without complication, and requires but little attention. The process is almost self-regulating, much like that in the Aquarium, which renders the latter of such interest.

To secure the condition of heat, the plants should be exposed not too directly to the rays of the sun. If possible, the case should be so placed as to have the light of an adjoining window thrown in its rear.

A communication from Mr. Walter Elder was read, in which the writer traced the history of window gardening, and presented some thoughts on the moral and pleasing nature of the practice. It was the simplest branch of gardening, and the first to interest the mind with a love of flowering plants; it is the parent of exotic floriculture. Working people in large cities, who had not a foot of ground, made gardens upon the house-tops, and now Paris and other European cities are noted for them.

The French excel in balcony gardens.—Some window gardening is perhaps more universal among the working classes in Scotland than in any other country. It is in every house. The pious, peaceful, and moral nature of the people attaches them to home, and creates in them a desire to beautify it. The writer thought that the people of Philadelphia showed, several years ago, more taste for this branch of floriculture than now.

The communication closed with an allusion to the soothing influence of the culture of flowers on the mind. There was never a more propitious time for the culture of window plants than now, when the number of flowers subject to such treatment is greatly increased.

### Late Grafting.

It is generally supposed that grafting must be done early in the spring, or it will not succeed; the rule is to graft before vegetation has begun. We have at various times practiced grafting up to the beginning of the second week in June, and with pretty uniform success. The chief difficulty to contend with is to keep the grafts from drying up on the one hand, or to prevent them from growing. When an ice house is at hand, the difficulty is somewhat under control. Early in the season we received valuable grafts from Mr. Wilder, Dr. Brinkle, and others. Our purpose was to set them at once; but absence and other causes made it quite impossible, and they remained in the cellar, covered with sand, till the 28th of May, when they were put in, some of them quite dry and somewhat shriveled. They were cut into lengths of three or four inches, and most of them inserted by the common mode of split grafting. With some, however, the usual T cut for budding was made in the bark, the graft cut sloping at the end, inserted under the bark, and secured by tying. All were thinly coated with grafting wax. Upwards of fifty grafts (apples and pears) were put in, and, with one single exception, are growing as finely as could be wished. The exception is a graft of two-year old wood, and is breaking rather feebly, which was to be expected. We call attention to this late grafting, not as a remarkable novelty, but that our readers may know that late grafting may be successfully performed. Valuable grafts are sometimes thrown away, because it is supposed to be too late to put them in. In regard to the ripening of the wood, we have never had a late graft winter killed. There is no doubt a limit beyond which we cannot go; but that limit we have not yet ascertained. The grafts put in by the T cut are growing quite as well as those put in the split. The T cut is more rapidly performed, but neither process requires much time.—*Horticulturist*.

**HOLLYHOCKS.**—To those lovers of flowers who object to the hollyhock on account of the height to which the flower stem rises, we would suggest a remedy. Instead of one, two or three spikes, encourage four, five, or even six, to rise, and when they have reached an approved height, cut their tops off, and the habit of the plant will be entirely altered. If one spike is fixed in the centre, and left taller than those which surround it, the effect is highly pleasing. Beyond this, there are many varieties naturally of a dwarf or bushy habit. Most of the leading modern kinds commence the formation of flower buds at about two feet from the ground.—*W. Paul*.

**GROWING THE TOMATO.**—One would suppose that at this late day we know pretty much all about cultivating the tomato; but it seems that we do not, inasmuch as we daily see recommendations as to the best method of getting the most fruit. Some people train the vines over the most elaborate tressel-work or frames, at no little expense; others trellis them; others stick them with brush about the size or a little larger than that used for peas; others simply throw down brush for them to run over; and others allow the vines to creep over the ground without any support, only previously mulching the ground well with grass or straw.

We have tried every mode herein mentioned, and we have found that whether the plants are stuck, brushed, or allowed to run unsupported over the ground the yield is about the same. Frames and trellises are not so productive. We prefer the sticking process. It produces full as great a crop as any other mode; and if the brush is firmly inserted in the ground, it admits of passing between the rows to pick the fruit. When the vines are allowed to run over the ground unsupported, however much the ground may be mulched, the flavor of the tomato is more or less extracted by the natural attraction of the soil, by which the fruit is rendered almost worthless; besides the vines are all in a mass, and to get at the fruit is inconvenient to the picker and injurious to the crop.—*German-town Telegraph*.

### The Dairy.

#### Rearing Calves on Milk and Linseed Meal.

No doubt but the best and most proper food for the calf is its own dam's milk; for it is a true food, in which the components of nutrition are so nicely balanced by the all-wise and beneficent Creator as to set at naught all human compositions; but it is of so much value for human consumption, that it becomes necessary to economise it, and make imitations of it, though at a very humble distance; and thus it is that science comes to our aid. Professor Johnston says, in his "Lectures on Agricultural Chemistry," that "while the calf is young, during the first two or three weeks, its bones and muscles chiefly grow. It requires the materials of these therefore, more than fat, and hence half the milk it gets at first may be skimmed, and a little bean meal may be mixed with it to add more of the casein or curd, out of which the muscles are formed. The costive effects of the bean meal are to be guarded against by occasional medicine if required. In the next stage more fat is necessary; and in the third week,

at latest, full milk should be given, and more milk than the mother supplies if the calf requires it; or, instead of the cream, a less costly kind of fat may be used. Oilcake finely crushed, or linseed-meal, or even linseed oil, may supply at a cheap rate the fat which in form of cream, sells for much money; and instead of additional milk, bean-meal in large quantities may be tried and if cautiously and skilfully used, the best effects on the size of the calf and firmness of the veal may be anticipated."

The scientific note from Professor Johnston has engaged the attention of many stockmasters in Ireland, and among the rest, Mr. C. Beamish, of Cork, who adopted it and brought it to a regular system on an extensive scale. His formula for compounding the mucilage is as follows: thirty quarts of boiling water are poured on three quarts of linseed-meal and four quarts of bean-meal. It is then covered up close; and in twenty-four hours added to thirty-one quarts of boiling water, then put on the fire, pouring it in slowly, and stirring it constantly to prevent lumps, with a perforated wooden paddle, so as to produce perfect incorporation. After boiling thirty minutes, the prepared mucilage or gruel is put for use, and should be given blood or lukewarm to the calves, mixing it in small quantities at first with milk, say one-fourth mucilage with three-fourths milk, progressively increasing it, so that by the end of a fortnight it will be in equal parts: by the end of the third week, one and a-half mucilage to one part milk; by the end of the fourth week the mucilage may be given in double the quantity of milk, and skim milk substituted for new milk; and by the end of the sixth week, the mucilage will be gradually increased in the proportion of two and a-half to one of milk; and from that on till the tenth week the milk may be gradually reduced, so that by that time they may be fed wholly on mucilage till they are fifteen or sixteen weeks old, when they may be weaned.

During all this time, if too early in the season to put out the calves, they should be comfortably housed, well ventilated, and kept perfectly sweet and clean; a little sweet hay tied in bundles and suspended, so that they may play with it and learn to nibble and eat it; and a little pounded chalk, mixed with salt, given in troughs to lick at pleasure, which prevents acidity in the stomach, and the due formation of cud. Small lumps of linseed cake should be given in other troughs, which they will soon learn to suck, if a little pains are taken to put a bit in their mouths after they have taken in their mouths after they have taken their meals of milk and mucilage. When housed it will be advisable to have a separate pen for each calf of sufficient size to walk about, so that they do not get into the habit of sucking each other and swallowing the air, which, united with the curd by the regurgitating process going on in the stomach, forms round balls which are indigesti-

ble, and is the fertile cause of the death of many promising animals. The following scale of quantity of milk or milk and mucilage combined for each calf may be useful, but should be altered according to circumstances: For the first week the calf may get from three or four quarts daily; for the second week, four to five quarts; fifth and sixth weeks, eight to ten quarts; six to eight weeks, ten to twelve quarts per day, and so on, increasing the quantity about one quart per week per calf till weaning time.

Some parties do not give so much liquid food per day, but make it up by giving them finely-cut roots, dry oatmeal, &c.; but the animals are much too young for such food, though they may get the minced roots so as to train them into their use. Hay tea is an admirable thing also to mix with the mucilage and milk, as it contains a large amount of nutriment in a soluble form.

In the summer time the calves may be left out on the grass, both day and night, in a fort night after they are calved (and fed as already described they should be in the house); but a warm sheltered paddock should be provided for them, and in wet weather they should have access to a covered shed — *Irish Farmer's Gazette*.

---

## The Poultry Yard.

---

### A Profitable Hennerly.

Mr. Wingate's poultry house and yard are well planned—in winter the hens have a warm and commodious apartment, and in summer they are given free use of the yard, but never allowed out of it. Fresh water is kept by them all the time. The apartment in which the hens roost is about ten feet square, and it is also provided with several box nests. There are two perches for the hens to roost upon, about eighteen inches apart, and under them is a broad shelf for the purpose of catching the droppings. This is supplied daily with loam, ashes, stable-dressing, &c., and is scraped off each morning. Mr. Wingate finds this a most efficient fertilizer, applying it to his grapevines and also to other garden crops, with the best results. Adjoining this room is a larger one, which is used for the winter quarters of the poultry, connected with the other by a sliding door for the use of the poultry. Each fall Mr. W. collects from the streets about two cart loads of fallen leaves, and places them upon the floor of this room; consequently the hens have a warm, dry, and comfortable chance all winter. But this is not all; the leaves thus used become partially rotted, and with the droppings of the poultry, make a considerable pile of excellent dressing. Farmers and others who keep hens, and allow them

to freeze to death upon the cold, damp manure heap of the shed, should make a note of this.

In feeding his hens, Mr. W. makes use of the waste from the kitchen, as he keeps no pig. The potatoes, &c. are mashed up and mixed with oat-meal; and besides this, corn is given them in sufficient amount to keep them in good condition. He also uses what bones accumulate from the meat used in the family. For the purpose of crushing these up fine he has a substantial block with the top dug out in the form a bowl, into which the bones are placed, and with an axe reduced to a form readily eaten by the hens. At present Mr. W. has twenty-four hens and a crower. He keeps the hens until they are three years old, then sells them in the fall, after the best season of laying is over. To replenish this number, he buys pullets of some good laying breed.

Mr. W. keeps a correct account of the number of eggs laid by his hens. The number of eggs laid each day are set down, and each month added up. The account of eggs laid last year, (1861) by 23 hens, as follows:

|                    |         |                     |           |
|--------------------|---------|---------------------|-----------|
| January . . . . .  | 48 Eggs | July . . . . .      | 345 Eggs. |
| February . . . . . | 169 "   | August . . . . .    | 309 "     |
| March . . . . .    | 357 "   | September . . . . . | 241 "     |
| April . . . . .    | 393 "   | October . . . . .   | 95 "      |
| May . . . . .      | 473 "   | November . . . . .  | 18 "      |
| June . . . . .     | 403 "   | December . . . . .  | 18 "      |

In other words, 239 dozens of eggs, which at 15 cents per dozen—the average price during the year—would amount to \$35.85. The cost of keeping the hens for a year, Mr. W. considers to be \$8, as the waste from the house he does not reckon at full value. This is a profitable hen-nery, and is a good paying branch of Mr. Wingate's establishment.—*Maine Farmer.*

**LICE IN FOWLS**—Poultry-houses floored with beaten or well-rammed clay are said to be less infected with lice than houses which have sandy floors. In this, however, as in other departments of stock keeping, cleanliness is, after all, the best preventive. Cleanliness of the house and cleanliness of the hen. To secure the latter, let a plentiful supply of pure fresh water be given to them; and a dust bath should form an essential part of the furniture of a hen-house. A correspondent of a colonial paper suggests that to exterminate lice in fowls, they should be fed for several days on coarse meal wet with water, and sulphur mixed with it; the nests being at the same time thoroughly cleansed, the house fumigated with tobacco, and all the roots and wood-work white-washed with fresh lime mixed with sulphur or tobacco.—*Mark Lane Express.*

**HENS EATING EGGS.**—A writer in the *London Field*, says: "That hens eating their eggs is often owing to the form of the nest, and suggests that the proper form is that of a

plate; shallow, that she may not have to jump down on the eggs, and flat on the bottom, so that when she treads on them they will roll aside, and let her feet slip easily between them. She can then pass her bill among them, as she tucks them up under her, and shuffles them together with her wing without hurting them. If on the contrary, the nest is made in the form of a basin, the eggs press against each other, and are liable to be crushed by her efforts to put her feet between them, or to alter their position with her beak and wings. When an egg is broken most hens will eat it, and as hatching approaches, the eggs become more brittle; and in a deep or badly formed nest the chicks are very apt to be crushed and killed between the other eggs, by the movements of the hen."

### Production of Poultry and its Produce.

There was a time—and compared with the age of a nation and civilization, not so very long since—when to enjoy the luxury of a salad or a cauliflower it was necessary for the wealthy and the titled, and even for the sovereign herself, to send an express to the continent in order to obtain it. Doubtless, the farmers of that day thought it beneath the dignity of their cloth to devote any portion of their time, attention, or land to so insignificant and ignoble a species of produce. It might do very well for the poor people of France and the Low Countries to fiddle themselves about such trifling productions, but an English farmer had something more worthy of his attention to look after than pot-herbs and lettuces, with their accompaniments. But the day is gone by, and these things are cultivated in old England with as much success and to as great an extent as on the continent; and any farmer has now only to step out at his back door into the kitchen garden attached to every house in the country to supply himself with whatever of culinary or other vegetables he delights in.

There are, however, still articles of daily consumption, the production of which in England is far from being commensurate with the consumption or with the capabilities of the soil, and for a large supply of which we are indebted to our neighbours, the French and Belgians, to an extent that will appear apocryphal to those who are not initiated into the history and mystery of the Board of Trade returns. We refer to poultry and its produce, in the raising of which the British farmers are far behind their neighbours.

A stimulus, it is true, has been given to this branch of rural economy the last ten years, but at present the "poultry mania," as it is justly termed, is chiefly confined to amateur breeders. In order to extend and diffuse the "poultry mania" amongst the agricultural classes, or rather

to induce them to pay greater attention to the business of rearing and fattening fowls for the market, we will place before them the returns of the Board of Trade of the quantity of eggs and poultry imported, the former for the last ten years, whilst the latter since the reduction of the duty not being inserted in the returns, we can only give them for a limited period.

With regard to eggs, then, the following are the average numbers per annum imported since 1828, taking every five years:

| <i>Average Annual Import of Eggs from</i> |             |
|-------------------------------------------|-------------|
| 1828 to 1832 inclusive.. ..               | 61,431,062  |
| 1833 to 1838 .. ..                        | 68,493,516  |
| 1838 to 1842 .. ..                        | 91,393,632  |
| 1843 to 1847 .. ..                        | 72,690,051  |
| 1848 to 1852 .. ..                        | 103,120,221 |
| 1853 to 1857 .. ..                        | 147,342,219 |
| 1858 to 1861 .. ..                        | 163,581,140 |

There has, therefore, been a gradual increase in the supply ever since 1828, with the exception of the fourth average; but to show the enormous extent which it has now reached, we may state that whereas in 1844 the quantity imported was 70,415,931, in 1861 it reached 203,313,360. And, if we reckon the cost price of these at 4d per doz, their value is £282,379 10s, upwards of a quarter million sterling for a species of produce that could with the greatest ease be raised at home. With regard to the poultry imported there is reason to believe that it has increased in an equal proportion. The returns have not noticed the same since 1856, but for that and the two previous years the imports were in value as follows:

|            |         |
|------------|---------|
| 1854 .. .. | £38,876 |
| 1855 .. .. | 42,075  |
| 1856 .. .. | 48,230  |

So that the increase was about 25 per cent. on those three years, and has probably been quite in an equal proportion since, making up an aggregate amount for 1861 of fully £360,000 for poultry and eggs.

The number of eggs sent from France is not so surprising, when we take into account that every farmer has his *basse-cule*, or fowl yard, the produce of which constitutes no inconsiderable item in the accounts of the year. M. de Livergne, in comparing the produce of the United Kingdom with that of France, states that while the poultry of the former amounts to only twenty million francs (£800,000,) that of the latter country amounts to two hundred million francs (or £8,000,000 sterling); there is, therefore, a large margin left from the home consumption to be exported.

That the farmers would find it to their interest to cultivate more sedulously this branch of rural economy there cannot be a doubt. In London there is always a demand. Like all other provisions, there are different periods for different prices, and here it is that poultry shows

do much good in offering premiums for early maturity. If those who have facilities for rearing chickens would do so in January, or even in December, and bring them to market in a fat state in April, May, and June, they cannot fail to receive a remunerating price. Three pounds per dozen is a common value for fowls four months old. At this season, less than two guineas would be ridiculously low.

There is a collateral advantage to the farmer in keeping a large stock of fowls. The inferior grain could then be profitably consumed on the farm at a remunerating price, instead of being subject to the fluctuations of the market. Nor is the dung that would be made an object of no account. It is certain that fowls' dung is exceedingly valuable, and where large numbers are kept a considerable quantity would be made in a year. For the present we leave the subject for the consideration of those whom it concerns, but may probably recur to it on some future occasion.—*Mark-lane Express.*

## Veterinary Department.

(Conducted by A. Smith, V. S.)

### Umbilical Hernia.

The protrusion of any portion of bowel through the umbilicus or navel, forming a tumor at that part is what is understood by umbilical hernia. The navel of the young animal prior to birth is open for the purpose of giving passage to the umbilical cord or naval string; this opening after birth becomes closed, and the vessel of the cord obliterated.

It sometimes happens that closure of the aperture does not take place, and a portion of omentum or intestine becomes protruded, constituting the hernia in question. However, in other cases it arises from blows or from the animal running and leaping, &c. The following is such a case.

About the end of July last, I was requested by a gentleman of this city to examine a thoroughbred filly, about one year old, that was affected with umbilical hernia. The tumor was about half as large as a man's fist, and increasing in size. The owner was anxious to have something done, if not to cure, at least to prevent the enlargement of the rupture; my opinion of the case was to operate immediately, as from the age and constitution of the filly the danger was

not great, and the chances were the operation would prove successful.

On Friday, the 1st of August, the filly was brought to my infirmary, and having lessened the contents of the bowels by giving laxative medicine and clysters, on the first Tuesday following her admission, I operated in the following manner:

Had the animal cast and turned upon her back and secured in the same manner as for castration. I proceeded to return the protruding portion of gut, which was easily done when in that position. The reduction effected, I pinched up the skin and passed an iron skewer about four inches in length through the skin and abdominal muscles, bringing the ruptured edges of the muscles together; taking care not to injure the intestine by guiding the point of the skewer with the fore-finger of my left hand. I secured the skewer in its place with a piece of twine, in the same manner as the pin is fastened in a horse's neck after the operation of blood letting. I then passed a second and third skewer through the skin only, anterior and posterior to the first, secured in the same manner, and the operation was concluded.

Next day the filly was a little feverish, and a slight swelling appearing in front of the rupture which continued to increase until Saturday, the 8th, when one of the skewers sloughed out, and on the day following the other did likewise; the ligatures and skewers having done their duty. During the time the swelling existed the abdomen was fermented with hot water several times a day, and a few doses of febrifuge medicine was administered, also clysters, and the animal kept continually in a standing posture. The symptoms now continued favorable, the swelling gradually decreasing, and on the 18th my patient was dismissed convalescent. A.S.

#### Rabies in a Horse.

*Communicated to the "Veterinarian" by R. H. Dyer, Veterinary Surgeon, Waterford.*

A few weeks since, I promised to send you an account of a case of rabies in a horse, but circumstances over which I have had no control have prevented my doing so till now. In the meantime, I have been endeavouring to ascertain with certainty when the animal was bitten.

No person can or will say, however, whether he was bitten or not, and the only evidence to be procured, is, that several mad dogs have been in the neighbourhood, and that many animals have been bitten, and further, that in every case the animals so bitten were at once destroyed.

According to the evidence it appears that, the horse in question was taken ill on Saturday, February 22nd, on which day the owner applied to me for a colic draught, such as was sent to a neighbour of his a short time before.

I made some enquiries as to the symptoms present, when he replied that the animal was in pain and had no evacuation either from the bladder or bowels. He took with him an ordinary colic draught, which, however, did not afford any relief, for, on the following morning, Sunday, I was requested to see the horse; he being sent to my place of business. When my attention was first directed to him he was standing side by side with a mare, and I enquired how long he had been blind. The owner answered he did not know he was blind, but that he had noticed something "odd about him" for he blundered about, and did not seem to know what he was doing. On approaching him he snapped at me, which led me to inquire if he was in the habit of biting. The man answered in the negative. I said, "He has an appearance akin to that of a mad dog. The saliva was flowing from his mouth at this time. The moment I made use of the term mad dog neither the owner nor his servant would approach the animal. I suspected the horse had been bitten, but I could not elicit from them any information to lead me to a correct decision. They merely said that a mad dog had passed through their premises about three weeks before, and it was known he had bitten several animals in his progress.

The symptoms present were as follows. The horse was very restless and snapping at everything within his reach, excepting the mare which was with him. He never attempted that I am aware of to injure her. On feeling his pulse I did not detect any marked peculiarity in it, excepting a prolongation occasionally of its beat. The respiration, however, was very much accelerated, which seemed somewhat strange, considering that the pulse remained unaltered. I made a special remark about this at the time, I examined every part of the animal, but did not detect any evidence of a bite. The prominent symptoms were total blindness, anastation of the urinary secretion, discharge of large quantities of saliva, increasing restlessness, and occasional attempts to bite those near him. He also had a most ferocious look.

I administered a sedative draught with great difficulty. The act of giving the medicine brought on a severe paroxysm. He became almost frantic. Being much worse in a couple of hours I attempted to administer another drench, but found it to be impracticable. Every at-

tempt at introducing the horn into his mouth made him furious. He would throw himself upon the ground—not fall down,—as if determined to break his neck—he would rise again, and stagger about the yard, all the time snapping at the rope by which he was held. At length finding that he was becoming dangerous, I secured his legs when down, and kept him in that position, which made him if possible more frantic. At this time the owner, seeing the horse secured, felt more at ease, and approached within a couple of yards of him. He soon consented to my destroying him, which I did by opening the right jugular vein and blowing into it. This took place about three p. m., and five hours after I first saw him. For the last three hours, in particular, the animal had been most dangerous to approach or to handle.

The next morning I examined the interior of the body. Nothing seemed amiss except the heart, which was greatly dilated, pale, and soft in texture. The brain was afterwards examined in the presence of a medical friend. We found the membranes very much inflamed, especially at the base of the brain. Although it was evident that the base of the organ had suffered most, we were of opinion that the substance of the brain in general gave indications of disease. I have since been told that many other animals have been bitten by dogs supposed to be mad. From what I can learn, it seems that about three weeks elapse before the bitten animals are seen to suffer. The black mare, whose companion the horse was, has been attacked since, and, I believe, was destroyed. It is almost impossible here to trace things to their source, for the country people will afford no assistance. The desire to stifle all information abounds with them. I have not added much to that which is already known of this disease, but such as that case is, it is at your service.

## Miscellaneous.

### Scottish Anecdotes.

#### *Editors of the Canadian Agriculturist,—*

In your May number, dated 16th, there is an original anecdote of Burns, the first time I ever saw it imputed to Burns. It is said there are always two ways of telling a story. I recollect some forty years ago or more, my mother telling me the story, but she imputed it to Ayrshire Will, a crazy sort of an individual who had a great propensity for rhyming after anything that you would say to him. Lord Kilmarnock and Mr. Boyd (not lord Boyd) were out taking a walk, when they saw Will coming to meet them. It was arranged to say something to Will that he could not rhyme, so both

said "Boo," to him, when he addressed them thus :—

Ther's Lord Kilmarnock and Mr. Boyd,  
O' sense and manners they are void,  
They'r like the Bill among the Kye  
Plays "Boo ! to iolk as they gang by."

My mother was an Ayrshire lass, and she had many of these stories to tell me. I recollect another of the same individual, and if you can devote a little more room in your valuable paper, it may please some of your readers. For myself I take pleasure in such. The Earl of Eglington, coming upon Will resting on the road side, as if asleep; the Earl awoke him and asked him what he was doing there, "I just sat down to rest, and fell asleep, and I was dreaming the Earl asked me what I was dreaming about. I dreamed that your lady gave me half-a-pound of tea, and your honour gave me two pounds of sugar." "Aye, but," says the Earl, "Will, you know dreams are contrary," meaning that he was not to get anything. "Well, if they are," says Will, "you can give me the tea," and let her ladyship give me the sugar." Another of the same "Daft Will Spier," who was a privileged hunter of Eglington Castle and grounds. He was discovered one day taking a near land cut, and crossing a fence in the demesne. The Earl called out, "Come back, sir, that's not the road." "Do ye ken," said Will "whaur I'm gain?" "No," replied his lordship, "Weel hoo the deil do ye ken whether this be the road or no?"

North Leeds, 1862.

THE AGE OF OUR EARTH.—Among the astounding discoveries of modern science is that of the immense periods which have passed in the gradual formation of the earth. So vast were the cycles of the time preceding even the appearance of man on the surface of our globe, that our own period seems as yesterday when compared with the epochs that have gone before it. Had we only the evidence of the deposits of rocks heaped above each other in regular strata by the slow accumulation of materials, they alone would convince us of the long and slow maturing of God's work on earth: but when we add to these the successive populations of whose life this world has been the theater, and whose remains are hidden in the rocks into which the mud or sand or soil of whatever kind on which they lived has hardened in the course of time—or the enormous chains of mountains whose upheaval divided these periods of quiet accumulation by great convulsions—or the changes of a different nature in the configuration of our globe, as the sinking of lands beneath the ocean, or the gradual rising of continents and islands above;—or the wearing of great river beds, or the filling of extensive water basins, till marshes first and then dry land succeeded to inland seas

—or the slow growth of coral reefs, those wonderful sea-walks, raised by the little ocean-architects whose own bodies furnish both the building stones and the cement that binds them together, and who have worked so busily during the long centuries, that there are extensive countries, mountain chains, islands, and long lines of coast consisting solely of their remains—or the countless forests that have grown up, flourished, died and decayed to fill the store-houses of coal that feed the fires of the human race to-day,—if we consider all these records of the past, the intellect fails to grasp a chronology for which our experience furnishes no data, and time that lies behind us seems as much an eternity to our conception as the future that stretches indefinitely before us.—*Agassiz.*

**LEeks, GARLICK, AND ONIONS**—Shakespeare, as we all remember, in his play of Henry V., refers to the leek; and Gower asks Fluellen: "But why wear you leek to-day, St. Davy's day is past?" Fluellen desires Pistol to eat it, although he complains and says: "I am qualmish at the smell of leek." The Emperor Nero, we can assure Signor Mario, ate them in large quantities to improve his voice. The Egyptians use them as a sauce with roast meat, or for breakfast with bread. We read in the book of Numbers of the Israelites murmuring for the onions, leeks, and garlic of the Egyptians during their sojourn in the desert. Garlic was most esteemed by the ancients. The Romans and Greeks gave it to their soldiers to excite their courage, and to their labourers to strengthen them under their toil. Though they are so sharp, and "move tears" by their smell, the onion tribe has never been beneath the notice of the truly great. Napoleon Bonaparte devoured them greedily. One of the most favorite dishes was a leg of mutton, stuffed with sage and onions—On one occasion he ate so voraciously of it, that he was seized with a violent fit of indigestion, and unable to attend to his military duties. The conqueror of Marengo stayed by sage and onions! Here's food for moral zing.

**OBSTINACY OF THE SEA HORSE**—The walrus is an obstinate animal, and does not fly on the approach of man; on the contrary, forming themselves into a body, they go and meet him, and resist any attempt on his part to proceed. When a company of travellers meet these animals on the shore, they are forced to fight their way through them: and if the walruses are pelted with stones, they gnaw them with their teeth, but afterwards attack the men with redoubled fury, rending the air with the most tremendous growling. These animals seem to be fully aware of the effect of united resistance and attack, and also of the utility of keeping in masses and ranks; for, should any one of them attempt to retreat, those in his rear fall upon,

and compel him to keep in the ranks, or kill him. Sometimes it happens that, when one walrus attempts to stop another, who is retreating, they all begin to suspect each other of being inclined to fly, and, in that case, the contest often becomes universal. When two are fighting with one, the others come to the aid of the weaker side. While they are thus fighting on the land, others that are in the water raise their heads, and look on for a time, till they also become enraged, swim to shore, and join in the combat.—*Cassell's Illustrated Natural History.*

## GRASS

BY DR. JOSEPH REYNOLDS.

It groweth everywhere. Its tender blade  
Shooteth in the sunshine and in the shade.  
It groweth on the hill-side, and the plain,  
By the sheltering hedge, in the shady lane.  
It springs by the roadside, under our feet,  
In the garden—where beds and borders meet;  
Under the shrubs, where blooms the scented rose,  
And the wild jasmine or sweet almond grows.  
It creeps up the bank, it runs down the slope,  
It springs with the crocus under the cope  
In the early spring, and stays in the fall  
With the pansy that peeps under the wall;  
In the fresh meadow, where the waters gleam,  
In the clear sunlight, and the sparkling stream  
Winds its course—now hidden, and now seen—  
It spreads its modest, cheerful coat of green.  
It groweth everywhere: on the mountain,  
In the valley, by the springing fountain;  
In the forest, in the field, on the beach,  
Just where the daily flowing tide doth reach.  
It creepeth close by the shore of the lake,  
Where its soft rootlets seek their thirst to slake;  
The waves that ceaseless lap its foam-crowned tip  
Kiss the green leaflets that stoop down to sip.  
The wild deer from the wood crops the smooth turf  
As early he comes to sport in the surf.  
The herds of the prairies, with the wild ass,  
All find their homes in wide oceans of grass;  
The droves of mustangs on the Mexican plains,  
The Tartar's wild horse in the Afghan domains,  
The goats of the Alps, that climb on the rocks,  
The horned zebu, and the fleet springboks,  
All ranging free as the birds in the skies,  
Crop the sweet herbage that nature supplies.  
The soft, modest grass is everywhere seen,  
Spreading its carpet of beautiful green,  
To cover the scars man makes in the earth,  
And smooth o'er the soul that giveth it birth.  
When hoofs of war-horses trample the soil,  
In the rage and strife of battle's turmoil,  
When war's iron storm tears up the fair plain,  
And ridgeth it o'er with graves of the slain,  
The soft grass, in pity, spreads o'er the scene,  
Covering it up with its mantle of green.

—*New England Farmer.*

**MATERNAL HABITS OF THE KANGAROO**—As most of my readers are aware, the kangaroo like nearly every other animal indigenous to Australia, is "marsupial" i. e., the female is provided with a pouch outside the bottom of the stomach, in which are the teats, to one of which the young foetus is attached during the period of gestation, I believe about sixty days; and when fully formed—soon, in fact, as the young one begins to live—it becomes detached from the teat, which now supplies it with milk. When the young one leaves the teat, it is in an equal state of development to the new born offspring of any other animal; in fact, this pouch appears to be the womb of all these marsupial animals, and not, as many suppose, merely a place of refuge in which the old mother carries her young. Here the young one at first principally lives, till able to run at the foot of the mother; but, even then, when danger is near, it tumbles head over heels into the pouch for protection; and it is wonderful how quickly the old doe can pick up the joey when running at full speed, and shove it into the pouch, its pretty little face always outside. There she carries it till hard pressed, when the love of life overcomes the love of the mother, and she then casts it away to save herself. This, in bush phraseology, is termed "dinging the joey." I once saw an eagle-hawk chasing a doe kangaroo with a heavy joey in the pouch through the forest. The cunning bird kept stroke for stroke with the kangaroo, which it hardly dare attack; but it well knew as soon as the old mother became exhausted, she would cast away the young one. Two ounces of kangaroo-shot from my gun, however, stopped the eagle's gallop. I might have killed the old kangaroo as well, but had not the heart, after seeing the struggle she was making to save the life of her offspring.—*Bush Wanderings of a Naturalist; by an old Bushman.*

**THE NEWSPAPER**—What charm then—what weird power lies in these straight lines of letters, that they should find the way to every house, and stir up a peculiar interest in every heart? They simply record the life and doings of our race. They give rude etchings and photographs of man in all the varying phases of his character—character developed in every possible condition—under every conceivable form of trial; and thus they appeal to our sympathies and desires in every way. The struggles and aims, the fears, ambitions, hopes, cares, passion, crimes and virtues of man are here set down faithfully in shorthand. The newspaper makes Shakespeares of us all. It furnishes us with an outline—it may be some fireside tragedy—we can at will fill up the sketch with details of the most romantic interest; the materials are given, we can weave them into a web hued and patterned as gorgeously as we please. It supplies us with a few bald facts relative to some mysterious occurrence; straightway we are absorbed in the exci-

ting process of completing the imperfect story, our minds pursuing a thousand probabilities, yet still left unfettered in a boundless universe of conjecture. The details of some strange scheme or deed are laid before us—at once all the faculties of the mind are engaged in the work of tracking out the hidden motives; unravelling the complications; developing the secret source or agency; in short, solving the mystery in what ever form it may present itself. Most people laugh at the countryman who wished a newspaper "wi' plenty o' guid murders in't." But the "guid murders" doubtless meant those which the utmost ingenuity of concealment had shrouded in thorough mystery; and the desire probably indicated—not a weakness—not an unnatural gloating over the most brutal form of guilt, but the strong, though morbid working of a high quality of mind.

The feeling of power evoked by the newspaper is another element of attraction in it; it sets before us all the kingdoms of the world, and all the glory of them; by it we sit in the councils of kings, and take part in those deliberations by which the destinies of the world are controlled; by it we stand in the assemblies of the wise, while genius displays all her dazzling treasures; and by it we can, with the disciples of science, explore, investigate, and acquire new riches of knowledge in every direction where the Creator's own hand has written the inexhaustless wonders of his wisdom.—*Good Words.*

**CONCRETE HOUSES.**—In reply to an inquirer I copy from the *Civil Engineer and Architect's Journal* for 1852, the following brief description of the erection of two houses in concrete:—"On the estate of East Cowes Park, Isle of Wight, adjoining Osborne, her Majesty's marine residence, two villas have been recently erected, under the direction of Mr. Langley, constructed entirely of concrete, composed of one part of Francis's Medina Cement, with seven of coarse gravel and grit, the gravel having been first carefully sifted clean and rendered perfectly free from sand. The gravel was dug on the estate, and the walls carried up, as well as the chimneys, by fixing two or three boards vertically, and filling in the concrete between about 12 to 14 inches thick, by which method, in consequence of the quick setting of the cement, boards were shifted every three or four hours as the work progressed. Even the arches were all turned in it, no bricks whatever being used. The method is not only extremely economical, but has the great desideratum of being perfectly free from damp, although the walls are not so thick as in the ordinary method of building by brick or stone. The absence of sand in the mixture is absolutely necessary, as every particle of sand engages a proportion of cement, or, in other words, deprives the gravel of so much strength, and materially deteriorates the work. We believe that a building-

society is about to be formed for the purpose of erecting many houses on the estate, with similar materials."—*London Field*

**MIGRATION OF EELS.**—A close observer assures us that the following interesting evolutions occur when eels come in from the sea: The aggregate shoal, about to ascend the inland streams, move up the shore of the river in the form of a long, dark, rope like body, in shape not unlike an enormous specimen of the animals which compose it. On reaching the first tributary, a portion, consisting of the number of eels adequate for peopling this stream, detaches itself from the main body and passes up; and, in the subsequent onward passage of the shoal, this marvelous system of detaching, on reaching the mouths of brooks, a proportionate quantity of the great advancing swarm, is repeated, until the entire number has been suitably provided with rivulets to revel in. Such being the wonderful instinct by which nature ordains that each stream be provided with a competent number of this migratory creature.—"*A Slice of Salmon*;" in *Macmillan's Magazine*.

**AN EAGLE'S STRATAGEM.**—As the mountains around the Königs Sea abound in chamois, the eagle very naturally resorts there; and opportunity is frequently afforded of witnessing his tactics, modified by circumstances. The following account gives an instance of most cunning stratagem; but it also shows how impotent for attack the eagle is when his victim is not entirely exposed. A good-sized chamois buck had got upon a ledge of rock, and was gazing downward and about him as these animals like to do. An eagle perceived him; but as the bird could not approach close to the rock on account of his breadth of wing, he resolved to obtain the prize he had marked as his own in another manner. So he sailed by the chamois on his narrow path as near as he dared come; then again and again; and as the animal retreated in order to quit his perilous position, the eagle, wheeling round in a smaller circle, met him instantly, to hem in and cut off his retreat. By thus rushing past within a few feet of him, and filling him with terror, he hoped to bewilder the chamois, and cause him to fall over the precipice, in which case he would have but to descend, and carry off his booty. And, in fact, the chamois, from trepidation probably, in turning a corner, slipped with one hind foot over the ledge. He lost his balance, and fell headlong over the rocks, as the eagle intended that he should. But after lodging for a short time on an intervening slope the carcass rolled off, and came toppling down into the lake. The whole proceedings had been watched by two persons in a boat. They now crossed to get the chamois; while the eagle, disappointed of his victim, wheeled above them, watching all they did.—*Forest Creatures*; by Charles Boner.]

**DANGEROUS COSMETICS.**—At a recent sitting of the French Academy of Medicine, Dr. Reveil read a paper on the necessity of preventing perfumers from selling poisonous or dangerous articles, which should be exclusively left to the responsibility of regular chemists, and not sold without a physician's prescription. "To show the danger there is in allowing the unchecked sale of certain compounds," he said "I need but state that arsenic, the acid nitrate of mercury, tartar emetic, cantharides, colchicum, and potassa caustica form part of their ingredients. The kind of soap called lettuce soap, which is sold with the announcement that it has been acknowledged by the Academy does not contain the slightest trace of lettuce. This and other soaps are all coloured green by the sesqui-oxide of chromium, or of a rose colour by the bi-sulphuret of mercury known as vermillion. Some that are cheaper contain 30 per cent, of insoluble matter, such as lime or plaster, while others contain animal nitrogenous matter which, having escaped the process of saponification, emits a bad smell when its solution is left exposed to the air. The various toilet vinegars are so far noxious that, being applied to the skin still impregnated with soap and water, they give rise to a decomposition, in consequence of which the fatty acids of soaps being insoluble in water, are not removed by washing, become rancid, and cause a chronic inflammation of the skin. The preparations employed for hair-dye under the pompous names of 'African Water,' 'Florida Water,' &c., all contain nitrate of silver, sulphur, oxide, and ete-tate of lead, sulphate of copper, and other noxious substances. All cosmetics for removing hairs or freckles are dangerous; the *lait antephe lique*, for instance, contains corrosive sublimate, and oxide of lead. Were a chemist to deliver such a remedy to a customer without a regular prescription, he would be liable to a fine of 6000f." Dr. Reveil concluded by expressing his regret that certain physicians should so far forget their own dignity as to lend the support of their names to such noxious inventions.—*Galigan's Messenger*.

**SINGULAR DOMICILES.**—Like other familiar birds, the sparrow sometimes builds its nest in very unsuspected localities, and there are several examples of their nests being placed in different parts of a ship's rigging. For example, while the Great Britain was lying in the Sandown graving dock, some sparrows built two nests in the "bunts" of the main and mizen topsails, i. e., the place where the sail is gathered up into a bundle near the mast. As the sail could not be set without disturbing the birds, the sailors augured a speedy and pleasant voyage. Mr. Thompson gives an instance of the sparrow building upon the furled sail of the *Aurora*, of Belfast; but as the sail was loosened during the second voyage to Glasgow, the nest was destroy-

ed and the eggs broken. Again, a pair of sparrows built their nests under the slings of the foreyard of the ship *Ann*, of Shields, just before leaving port, and, when the vessel creaked the Tyne, the birds went ashore and brought back materials wherewith to complete their home.—*Routledge's Natural History*.

**DOMESTIC SERVICE.**—We are reminded here of a good-hearted housemaid in a clergyman's family, whose eyesight was in danger before she let anybody know her troubles. She valued her "religious privileges," and bore with much for their sake; and as often as she believed she had made up her mind to leave her place, her master's discourse to her on the trials of life, and descriptions of the beauty of patience upset her resolution, and induced her to try again. She was expected to call the pupils (it was a school), at six, summer and winter, and to serve the warm water, light the fires, and serve the breakfast, have the school-room swept and in order, besides washing and dressing the little children, —her mistress thinking it quite hard work enough to be ready when the bell rang for prayers. All day the young woman was at work, full drive, as she and the cook must have been in a household of that size and construction. When the last of the family went to bed at eleven o'clock, she was set down to make her master's fine shirts, by a single candle in the kitchen, and she rarely went to bed before one or two, except on Sunday nights. When invited out to tea at holiday times, she was told that if she was not home before nine she would be locked out; and it was no empty threat. The only way to procure her a sociable evening was by offering her a bed. Moreover she was not allowed to go out without her workbag, in which was a pair of wristbands, or a shirt front, which she was to bring home finished. When asked why she put up with such treatment she alleged her unwillingness to give up her "religious privileges," and to inconvenience an inexperienced mistress. The state of her eyes settled the matter at last, and her sight was barely saved by a costly abstinence from work and wages. The mistress has probably learned from experience something of what it was she required. The family emigrated to a place where, if servants were to be had at all, they would certainly refuse to work both night and day, or at all more than suited their convenience.—*Edinburg Review*.

**MIGRATORY INSTINCT.**—The Tower of Babel heard the already recognized law of migration authoritatively promulgated, beheld it branded into the living tablets of human nature. And that law has never yet become effete: no portion of it has been annulled. Its operation—certainly never for long even suspended—has never ceased to afford evident tokens of its continuance. Look at the "Great Migration," as

it is called, which Europe saw before the Medæval times, and the colonizations of still much earlier periods, the irruptions of huge hordes of fierce herdsmen-warriors in many an age and many a country, in both Africa and Asia, upon lands and labours they knew not of, except as it were by a dim, dreamy-hearsay, myth-like both in its vague dimness and its fundamental element and substratum of truth. These illustrations of the instinct which impels the human species to migrate from scenes of failing capabilities and resources to newer ones of abundant supplies and exceeding susceptibility of development, are as numerous as the ages which have looked on man's existence, as striking as the succession of scenes that have ever newly presented to his wondering gaze, as he has been again, and yet again driven to seek some newer and fitter abiding place.—*Atkinson's Sketches in Natural History*.

**ANIMALS BECOMING PARENTS TOO EARLY.**—Victor Gilbert never allowed ewes to have lambs until they passed their third year; and the bucks were not used until they had arrived at full maturity. He, as well as many other sagacious stock-raisers that we might name, are probably conversant with the fact that during the period of growth and development up to maturity, the reproductive organs are dormant, while at the same time the nutritive function is wholly engaged in elaborating chyle and blood for the development of bone, muscle, and nerve, and that calling into requisition the reproductive or generative organs, before the animal has attained full growth must necessarily divert the elements of matter intended for nutrition from their legitimate channel, and direct them to the reproductive organs. A too early use of the purely animal function induces weakness and stunted growth.—*American Veterinary Surgeon*.

**FREAK OF AN AGRICULTURAL LOCOMOTIVE.**—On Wednesday evening last the inhabitants of the Bull Ring, Birmingham, were much alarmed by a loud crash at the premises of Mr. John Gregory, boot manufacturer, a few doors from Moor-street. On going into the street to ascertain the cause, it was found that a large agricultural locomotive, moved by steam power, had dashed into the door-way of Mr. Gregory, smashing it to pieces, as well as several shutters. It appears that the steam plough, with some half dozen waggons containing implements, left Mr. Smith's premises at Coven near Wolverhampton, Stratford-on-Avon, and was driven by steam power along the highway and through the principal streets of the borough. To avoid the hill of the Bull-Ring, the train (or such it was took the way of Carr's Lane, and Moor-street) On turning into the Bull Ring, from some misunderstanding as to the best direction to take so as to avoid accident, a sudden turn was given to the guiding wheel, and the ponderous mach-

ine, weighing 15 tons, and capable of drawing 50, jumped upon the pavement, and ran with great force against Mr. Gregory's shop. There were two men in charge of the agricultural train at the time, and both were at their post on the engine, and when it ran into the shop they had barely time to save themselves from being crushed to death by jumping off the machine. Fortunately the water in the boiler was rather low, and the steam not powerful at the time or the immense mass would either have fallen through the thin boarding of the shop flooring into the cellar, or, by going three or four inches farther, knocked down an iron pillar which supported the front of the house. The occurrence attracted an immense crowd of persons, doubtless increased by the novelty of its character. The ponderous machine once fixed in the doorway of the shop, the difficulty was to get it back again into the street, and nearly three hours elapsed before this was accomplished. It was found necessary to obtain the assistance of six of the corporation horses to effect its removal, and at eleven o'clock the train was again on its way to Stratford.

**THE CRAB THAT FEEDS ON COCONUTS.**—What a wonderful world it is in which you live, and how very numerous are the proofs of the wisdom and goodness of God in taking care of all his creatures! You may be quite sure that he will take care of you, seeing that there are none so mean and so little but what he makes provision for their wants. There is a curious example of the instinct which the Almighty gives to some of the creatures he has formed that I have a mind to relate. You have all seen crabs; but there is an odd kind of crab that you have not seen, which lives in the East Indies, and instead of finding its food in the sea some say that it climbs up, like a monkey, into a cocoa-tree, that it may dine and sup; at any rate it feeds on the fruit which falls from the branches. But how does it get at the kernel? for your own little teeth tell you that the shell of the coconut is anything but soft. The Creator has given its forelegs a pair of strong pinchers; with these it tears away the husk, piece by piece, from that end where the eyeholes are situated. It then hammers away till it has broken the shell open; then it turns it round, and by working into it by its hind claws, which are as hind legs, it gets out the sweet and juicy inside of the coconut. It goes every night to the sea to refresh itself, as one drinks a glass of water at supper time, before going to bed. This is a very strange example of what we call instinct, which means something in beasts, and birds, and fishes, and reptiles which is to them instead of the reason and conscience which God has given you. What an interesting illustration this little fact is of what the Bible says: "The eyes of all wait upon thee, and thou givest them their meat in due season. Thou openest thine hand, and satisfiest the desire of every living thing."

## THE INDEPENDENT FARMER.

Let sailors sing of the windy deep,  
Let soldiers praise their armour,  
But in my heart this toast I'll keep,  
The Independent Farmer.  
When first the rose in robe of green  
Unfolds its crimson lining,  
And 'round his cottage porch is seen  
The honeysuckle twining;  
When banks of bloom their sweetness yield,  
To bees that gather honey,  
He drives his team across the field,  
Where skies are soft and balmy.

The blackbird clucks behind the plough,  
The quail pipes loud and clearly,  
Yon orchard hides behind its bough  
The home he loves so dearly;  
The grey old barn, whose doors unfold  
His ample store in measure,  
More rich than heaps of hoarded gold,  
A precious, blessed treasure;  
But yonder in the porch there stands  
His wife, the lovely charmer,  
The sweetest rose on all his lands—  
The Independent Farmer.

To him the Spring comes dancingly,  
To him the Summer blushes,  
The Autumn smiles with mellow ray;  
He sleeps, old Winter hushes.  
He cares not how the world may move,  
No doubts nor fears confound him;  
His little flocks are linked in love,  
And household angels round him;  
He trusts in God and loves his wife,  
Nor griefs nor ills may harm her;  
He's nature's nobleman in life—  
The Independent Farmer.

**ABSORPTIVE POWER OF THE SOIL.**—No contrivance of science to the practice of agriculture is more calculated to arrest the attention of the farmer than the various observations which have been made within the last few years regarding the remarkable power the soil possesses of absorbing and retaining some of the indispensable elements of the plant. They are the more worthy of attention, inasmuch as the facts which have been determined are to a certain extent, opposed to some of the more commonly prevalent opinions. They lend but little countenance to the idea that the manure, when committed to the soil, lies there in a precarious condition, liable at any moment to be deprived of its soluble constituents by the rain, and of its volatile matters by the heat of the sun's rays; but, on the contrary, they tend to show that there is a conservative influence at work in the soil which imprisons these substances within it, and stores and preserves them for the future uses of the plant; and, what is more, it exercises this influence more powerfully on these substances which are most sparingly distributed throughout the soil, holding with the firm grasp of a miser

the potash and ammonia, but leaving the soda and lime, which are less important to the plant, at the mercy of the rain. The discovery of these facts has thrown an entire new light on the chemistry of the soil, for they have shown that it must be studied not merely by itself, but in relation to the various substances with which it comes in contact in the course of cultivation so as to trace the influences which they mutually exert, and thus a subject already sufficiently complex has become more difficult and laborious than it was before.—*Scottish Farmer*.

**"THE SPIRIT" IN GINGER BEER.**—As many temperance men are in the habit of drinking ginger beer under the impression that they are still "keeping the pledge," by abstaining from alcoholic liquor mixtures, it may perhaps be as well to tell them the real truth, that all good ginger beer contains a notable portion of spirit. The more the beer is "up," the more certain is it that alcohol is present. It is well known that ginger beer is made with sugar, ginger, &c.; and that it is "set" to ferment before it is bottled; now, it is during the fermentation of the sugar that spirit is produced, and, to show its presence, it can be easily separated by distillation. In making this statement we do not wish to bias the opinion of any man, but merely to correct a popular error—the belief that ginger beer is free from spirit!—*Septimus Piesse*.

**WHITEWASHING SHINGLES.**—Fresh or caustic lime, applied during the heat of summer, and after the wood has become thoroughly dried, enters the pores, and tends strongly to prevent decay. We have recently examined a board fence, which had been whitewashed in successive coats about 18 years ago. The boards were hard and sound, and had not become covered with moss, as was the case with another fence near, built at the same time. There is no doubt that a great advantage would result from whitewashing shingles before laying them. We have on a former occasion, given some instances of the durability thus imparted to them. A late number of the Boston Cultivator gives some additional examples. J. Mears of South Abington, performed the experiment in substance as follows:—He procured a vat (a lime vat at a tannery does well,) and applied salt with a small portion of potash to the lime, and immersed the shingles for four hours. The wash was afterwards brushed over the shingles when laid. This made a fire-proof roof on a blacksmith shop, now eleven years. Silas Brown, another correspondent says 25 years ago, he dipped shingles into a large kettle of lime wash to which salt had been added, and the whole kept boiling. A few shingles were dipped in all over at a time, long enough to soak them well, and then thrown aside to dry. In a short time all the shingles were thus prepared. Although what are termed "sap shingles," they have now lasted 25 years,

"and may do so for years to come." Several experiments of a similar character have been made since, with very successful results. *Cultivator*.

**WHY YOU CURSE THE SEED STORES.**—Do you want to know why? "Certainly?" Well then, let me tell you what has been often told you before:—*You plant too deep!* You don't believe it? I do, and I know it. There are hundreds of western farmers who as conscientiously believe that they must plant their corn from *four to six*, and in some instances, *eight inches* below the surface, as they believe there is a God in Israel, or a McCLELLAN to swear by. And you can't make them believe differently. They know; they've tried it; and their experience proves them and their practice right, all "book-learned" farmers to the contrary notwithstanding. And they despise "book-farmers" as bad as they hate gophers; and they kill all the gophers they can find.

Why do they plant so deep? Because they think the soil is peculiar. And in that they are right; it *is* peculiar. But *they* have made it so by their manipulations. They plow it when it is wet, harrow it when it is dry, and it is cloddy and lumpy, and rough as a Down-East field of stone. Then when planting comes they must get down to moist earth, or it will not germinate. They have to get down deep to do it. The roller is not known to the majority of farmers in corn culture. It ought to be. On such land as I have described, it ought to be used *before* the corn is planted, and again afterward. But I speak of the practice in corn planting show to the more clearly where the fault is in the case of smaller seeds, such as are purchased at the seed stores, planted in the gardens, and never grow at all! Why, only yesterday, I heard a lady say that she put her lettuce seed in *three inches deep*—down where the ground was moist—and it had not come up yet; and she was indignant! The seed stores were the matter, of course. "You know they *do* cheat so in seeds," said she to her companion. How sweet, and innocent, and indignant, and disappointed she looked, poor woman! For she was really a splendid woman; but she had not learned to garden. And she confessed that she planted her peas nearer a foot than six inches deep; and her flower seeds which she had got all the way from the Hub of Creation, were equally well planted—and O, the seeds men!

It should be remembered that the season is backward, the ground wet and cold in most localities; and then the fate of the good woman's seeds will be apparent. So of other sensible people who undertake farming and gardening. They know little of the laws of production, and less of the mode of manipulating soil. The more completely pulverized the soil the deeper they plant. It would seem hardly necessary to say

that in a fine, well pulverized soil, compact and clean, seed should *never* be planted deeper than three times its diameter; yet it is necessary to say so, and keep saying so, as long as children continue to be born, and seed is purchased and planted.—*Rural New Yorker*.

**THE SICK IN BED**—With a proper supply of windows, and a proper supply of fuel in open fireplaces, fresh air is comparatively easy to secure when your patient or patients are in bed. Never be afraid of open windows, then. People don't catch cold in bed. With proper bed-clothes, and hot bottles, if necessary, you can always keep a patient warm in bed. Never to allow a patient to be waked intentionally or accidentally, is a *sine qua non* of all good nursing. If he is roused out of his first sleep, he is almost certain to have no more sleep. It is a curious but quite intelligible fact, that if a patient is waked after a few hours' instead of a few minutes' sleep, he is much more likely to sleep again; because pain, like irritability of brain, perpetuates and intensifies itself. If you have gained more than the mere respite. Both the probability of recurrence and of the same intensity will be diminished, whereas both will be terribly increased by want of sleep. This is the reason why a patient waked in the early part of his sleep, loses not only his sleep, but his power to sleep. The more the sick sleep the better will they be able to sleep. A good nurse will always make sure that no door or windows in her patient's room shall rattle or creak; that no blind or curtain shall, by any change of wind through the open window, made to flap; especially will she be careful of this before she leaves her patient for the night. If you wait till your patient tells you or reminds you of these things, where is the use of us having a nurse?—*Florence Nightingale*.

**ANTIQUITY OF THE PIG**—The pig is the existing representative of a very ancient race of animals which lived and died upon this earth long before there were was Christians to devour, or Jews to abhor their flesh. The same species of wild boar that was hunted by our forefathers was contemporary with the mammoth, cave-bear, and the long haired rhinoceros. Some persons imagine that geology deals only with fossil shells or fishes; but there is a vast deal of interest attached to the geological history of the predecessors and representatives of our domestic animals. We know that the wild ancestor of our domestic pig was in existence before the separation of England from the Continent of Europe; and that the hunter, had hunters then lived, might have chased the boar through forests the sight of which is now occupied by the waves of the English Channel. Mammoth tigers, and rhinoceroses perished but the wild boar lived, and lives still on the Continent of Europe, though extinct here.—*Old Bones; of the Rev. W. S. Simonds*.

**COLLODION FOR GRAFTING**.—They are practicing a process in France, by which trees can be grafted at any season of the year, when mature buds can be obtained, whether the sap is in a flowing state or not. They remove a small piece of bark and wood, leaving a perfectly smooth surface, to which a similar piece, containing the bud intended to form the future tree is fitted. This is immediately sealed over with collodion, which forms a strong, impervious cuticle, insuring a perfect union of parts and a free circulation of sap, on approach of warm weather.—*Working Farmer*.

### Editorial Notices, &c.

THE WESTMINSTER REVIEW—July: New York; Leonard Scott & Co., 79 Fulton Street.

We have received from the Publishers, through Mr. Rowsell, of this city, the current number of the *Westminster*, the contents of which evince, as usual, great ability and ripe scholarship. The articles on the Life and Policy of Pitt; Election Expenses; English Rule in India; will be perused with interest by politicians of all shades of opinion; while those on the Philosophy of Sir William Hamilton; Celebrated Literary Friendships; and the Dawn of Animal Life, will be read with equal pleasure and improvement by all classes of people that possess the smallest share of literary and scientific taste. The department of this Review consisting of a running comment on the more salient points of the chief publications of the quarter on the most important branches of human knowledge, including politics and polemical theology, is of the greatest service to all such,—the number of whom is daily increasing in all the walks of life,—who desire to keep pace with the literary and scientific progress of the age. Although the theological bias of the *Westminster* is very far from being in accordance with the general belief of the age, an enquiring mind can scarcely afford to do without it, as its habit is to treat speculative subjects in a calm, free and liberal spirit. The article on Dr. Davidson's introduction to the Old Testament is a case in point. Such articles of the *Westminster* require to be read with one's eyes fully open, and to accept their conclusions only after the most thorough and careful examination.

BLACKWOOD'S MAGAZINE, for July, from the same publishers, is also to hand, and as usual contains articles of general interest and sterling worth.

The same publishers have issued an American edition of the *Farmers' Guide* to scientific and practical agriculture, by Henry Stephens, F. R. S., of Edinburgh, with notes and appendices by the late lamented Professor Norton, of Yale College: 2 vols. Royal octavo, 1600 pages, and numerous steel plates and engravings. This is allowed by the highest authorities both in Europe and America, to be the most complete work on Agriculture, both in theory and practice, ever published, and the American edition is printed from the stereotype plates of the Edinburgh edition, and may be procured in this country for about one-third of the price. *Five dollars only* for these two large beautifully got up volumes! We should like to see this inestimable work on the book-shelf of every farmer in Canada.

#### Horse Infirmary and Veterinary Establishment, Corner of Bay and Temperance Streets, Toronto, C. W.

A SMITH, Licentiate of the Edinburgh Veterinary College, and Veterinary Surgeon to the Board of Agriculture of U. C., begs to return his thanks to the Public generally for their support since opening the above mentioned establishment, and respectfully solicits a continuance of the same.

And also begs to announce that Veterinary Medicines of every description are constantly kept on hand:—Such as, Physic, Diuretic, Cough Cordial, Tonic Condition, and Worm Balls and Powders. The constituents composing the Cough-balls, have been found (by Professor Dick, of Edinburgh) most serviceable in alleviating many of the symptoms of Brokenwind or Heaves in Horses. Colic Draughts, &c., a mixture which owners of Horses should always have beside them.

Liniments for Sore-throat, Sprain, Curb, Spavin, Ringbone.

Blistering Ointments. Liquid and sweating Blisters.

*Horses bought and sold on commission.*

Toronto, Aug. 30th, 1862.

#### FOR SALE!

Ayrshire Cattle, Leicester Sheep, and Berkshire Pigs.

THE Subscriber offers several Young Bulls, Heifers and Cows, on very Liberal Terms. Specimens from his *Prize Herd* will be on Exhibition at Toronto, if all's well.

P. R. WRIGHT, Cobourg, C. W.

Aug. 30th, 1862.

6-mos.

#### THOROUGH-BRED STOCK FOR SALE

THE Subscriber has for sale DURHAM and GALLOWAY CATTLE, LEICESTER, COTSWOLD, and LINCOLNSHIRE SHEEP, Male and Female 10 Durham and Galloway Bull Calves—price from \$100 to \$200; 20 Shearling Rams, weighing from 230 to 285 lbs. each—Price from \$5 to \$100 each.

JOHN SNELL,

Edmonton P.O., C. W.

Four miles from Brampton Station G.T.R.

#### EAST RIDING YORK

Agricultural Society Fall Show,  
AT WELLINGTON HOTEL GROUNDS,  
MARKHAM VILLAGE, 9th October, 1862.

All Entries to be made by the evening of the 8th, or to be peremptorily excluded.

A. BARKER,  
Secretary.

#### THOROUGH BRED STOCK FOR SALE.

THE SUBSCRIBER has for Sale Durham and Galloway Cattle, male and female.

Leicester, Cotswold, Lincolnshire, Down and Cheviot Sheep; Cumberland and Yorkshire improved Pigs. All imported stock.

GEORGE MILLER.

Markham, June 3rd, 1862.

6t.

#### THE PROVINCIAL EXHIBITION

OF THE

AGRICULTURAL ASSOCIATION OF UPPER CANADA,

WILL be held at the City of Toronto on the 23rd, 24th, 25th, and 26th September next.

Persons intending to exhibit will please take notice that the entries of articles in the respective classes must be made on or before the undermentioned dates:—

Horses, Cattle, Sheep, Swine, Poultry, on or before Saturday, August 16th.

Grain, Field Roots, and other Farm Products, Agricultural Implements, Machinery, Manufactures generally, Saturday, August 30th.

Horticultural Products, Ladies' Work, the Fine Arts, &c., Saturday, September 13th.

Prize Lists and Blank Forms for making the entries upon may be had of the Secretaries of all Agricultural Societies and Mechanics' Institutes throughout the Province.

HUGH C. THOMSON,

Secretary Board of Agriculture.

Toronto, August 1, 1862.

## TO BE SOLD BY AUCTION,

On Thursday, Oct. 16, 1862,

**THE** well-known Herd of **NORTH DEVON CATTLE**, consisting of more than forty head of Cows, Bulls, and Heifers; one hundred and seventy West and Southdown Ewes and Rams; pure blooded Essex Pigs, in pairs fit for breeding.

Catalogues of description, with pedigrees, may be had fourteen days before the sale, on application at the office of the *Galt Reporter*, if by letter, prepaid. Credit of 12 months may be had on approved endorsed paper.

## THE SPLENDID FARM,

Consisting of upwards of **THREE HUNDRED ACRES**, to be sold by private bargain, on accommodating terms.

DANIEL TYE.

County Waterloo, Wilmot, August 1862. td

## THE JOURNAL OF THE BOARD OF ARTS AND MANUFACTURES, FOR UPPER CANADA,

Is Published on the first of every Month,

**A**T \$1 per annum for single copies, or to clubs of ten or more at 75 cents. per copy; to members of Mechanics' Institutes, and of Literary, Scientific, and Agricultural Societies, through their Secretary or other officer, 50 cents per annum per copy.

Subscriptions payable in advance.

Printed for the Board of Arts and Manufactures for Upper Canada, by W. C. CHEWETT & Co., King Street East, Toronto.

## The Agriculturist,

OR JOURNAL AND TRANSACTIONS OF THE BOARD  
OF AGRICULTURE OF UPPER CANADA,

**I**S published in Toronto on the 1st and 16th of each month.

**Subscription**—Half a dollar per annum for Single copies; Eleven copies for Five Dollars Twenty-two copies for Ten Dollars, &c.

**Editors**—Professor Buckland, of University College, Toronto, and Hugh C. Thomson, Secretary of the Board of Agriculture, Toronto, to whom all orders and remittances are to be addressed.

## Contents of this Number.

VOL. XIV.

TORONTO, SEPTEMBER 16, 1862.

No. 18.

### The Provincial Exhibition.

The approaching Exhibition of the Agricultural Association of Upper Canada, to be held in this city on the 23rd, 24th, 25th, and 26th inst., promises to surpass all former occasions. Although the entries in some of the departments have not yet been finally completed, sufficient is already known to warrant the conclusion, that in all the principal materials constituting the staple of a general Industrial Exhibition, the one now about to take place will not be found wanting. Although the present season has not been, in some important respects, the most favourable to agricultural pursuits, mainly in consequence of severe and extensive drought, during spring and the early part of summer, the subsequent genial rains and temperature soon produced an agreeable and astonishing change in the backward and languishing vegetation; and we have good reason for expecting to see at the approaching show, superior specimens of roots and cereals, as well as live stock in general.—There will also be several excellent specimens of animals, as well as mechanical productions, of kinds but little known in Canada.

His Excellency the Governor General will make his first visit to Upper Canada on this interesting occasion, who will be accompanied by Lady Monck and family, and also, it is expected, by the Governors of New Brunswick and Nova Scotia. The Local Committee, in connection with the citizens of Toronto, intend getting up a cheap Agricultural Banquet, at which

their Excellencies and other distinguished guests will be present. This will no doubt be a great attraction, and we hope to see many hundreds of our enterprising farmers, merchants, manufacturers, and others, gathered around the festive board, to do honour to the Representatives of Her Most Gracious Majesty on this continent, and the great cause of the agricultural, mechanical, and general industry of this rapidly improving Province. Public meetings will be held in the new Agricultural Hall, on the corner of Yonge and Queen Streets, on the evenings of Wednesday and Thursday of the Show-week, for addresses and discussions on subjects affecting the interests of Canadian agriculture.

### The Grain Aphis.

The following papers, involving somewhat of a controversy on the habits and effects of the Grain Aphis that has appeared in large numbers this season in several parts of Canada, and elsewhere, has been sent to us, and which we insert for the edification of our readers. Our columns are always open to communications whether original or otherwise that have a bearing on Agriculture or the mechanical arts; or that are in any way relate to such industry. We earnestly invite all parties connected or interested in such pursuits to send us concise statements of the results of their observations. It is in this way that truth is elicited and the knowledge of it diffused. Any display of acrimonious feeling in such mat-

ters should be equally deprecated and avoided. The Grain Aphis in some localities has unquestionably been productive of a greater extent of mischief than at an earlier period we had anticipated. Winter wheat as a general rule escaped, but late spring sorts have in some places suffered considerably. The chief injury inflicted consists in the lessening of the weight of the grain. The constant draining of the sap that flows into the ear, causes it to be very light, and in extreme cases, withered and almost worthless. No artificial means of a certain practical character for driving off or destroying this pest have yet been discovered, but nature in this, as in similar cases, has provided external enemies of these extensive tribes of depredators. The lady bugs, *coccinella*, as larvæ and beetles, the golden-eyed flies, *crysopa*, as larvæ, have been the past season in great numbers in wheat fields, busily engaged in devouring the plant lice. Whether they will happen next year is quite uncertain, and the causes of their recent increase are equally involved in obscurity. The army worm appeared in vast and destructive numbers last year, but we have heard little or nothing of it this season. Let us hope it will be the same with this grain aphis next year.

### Plant Louse, (Aphis) or Grain Destroyer.

*To the Editor of the Peterborough Review.*

DEAR SIR—Having heard much of this new and formidable-looking "depredator," I paid a visit on Monday last, to the farm of J. Harvey, Esq., one of our oldest and ablest agriculturists, where, after a careful examination of his crops, we drove to the farm of Mr. Alex. Rosborough, where, in company with Mr. R., we examined his beautiful and extensive fields of grain. Here, as at Mr. Harvey's, we found his Oats and Spring Wheat literally covered with this unwelcome visitor, giving to the heads of the Wheat in some of the fields a most extraordinary checkered appearance of red and green.

The insect, which in size is something less than the midge, presents, when viewed through a glass, a round oblong body of a pale reddish color, without covering and quite transparent; feelers and legs black, and the wings, which were found upon a few of them only, were long, of a greyish color, edged with black. We observed also that the bodies of some of them were of a dark greenish color; the number of these, however, was not very great; and although we discovered neither eggs nor deposit of any kind, we found the insects of various ages

and sizes; the young ones were without wings, or the appearance of any; those further advanced being partially fledged; while those of full growth were fully fledged, and were not long in showing us the use of them, by leaving for parts unknown. Their position upon the grain also attracted our attention, collected as they were in groups, sometimes to the extent of a dozen, heads downward, around the small stem which connects the chaff or husk of the grain with the stalk, and as busily engaged in obtaining their food as were ever a litter of pigs.

Mr. Harvey informed me that the number upon his wheat had diminished within the last four or five days by more than one-half, and that upon entering the field at the period named they would rise up in clouds and leave, proving pretty conclusively their intention of leaving us as soon as fledged.

On our way homewards we looked into several fields of Wheat and Oats, and found them all more or less affected; and I regret to state, upon authority which I believe to be thoroughly reliable, that the attack is very general in this part of the Province.

What amount of damage this heretofore unknown foe may do, is at this moment impossible to determine. That it will be serious I have little doubt. With the Wheat the process of filling appeared to be going on as usual, though I discovered in many places slight discolouration of the husk or chaff. Oats, however appeared to be suffering most; and in one field of Mr. Rosborough's, I believe there is fully one-third destroyed now.

Trusting that our fear may not be realized,  
I am your Obedient Servant,

W. S. CONGER.

Peterboro', Aug., 1862.

### *To the Editor of the Peterborough Review.*

SIR.—There were published in the last impression of the "Review" two communications respecting the appearance, this year, of an insect with whose antecedents but few Agriculturists in Canada seem to be familiar, and whose advent has, in consequence, produced a more or less considerable amount of alarm. The letters are from the pens of Professor Buckland and Mr. W. S. Conger respectively.

Professor Buckland's has been reproduced on more than one occasion since its original publication, and is, in my opinion, so satisfactory, as emanating from such a source, that, although subsequently to its perusal I personally inspected fields of both wheat and oats infested by the insect in question, I scarcely thought any further notice of it, unless some new light could be thrown upon the subject, would prove sufficiently interesting to your readers to encourage you to admit it within your columns; more especially as the "Canadian Agriculturist" of August

16, 1861, and of March 1, July 1, and July 16 of the current year, contains full reports of its appearance and of its operations.

Mr. Conger, however, is of a different opinion, and furnishes us with a very minute description of the insect, and with his melancholy forebodings as to its destructive qualities.

Unable to take for granted that his description is correct, and unwilling that erroneous notions should be circulated without contradiction, I hazard a remark or two in contravention of his assertions and his theories.

Mr. Conger calls the insect in question a "new and formidable looking depredator." If he refers to the "Canadian Agriculturist" of August 16, 1861, he will find that it is by no means new. The author of an article in that number, an article written a twelvemonth ago, says that "it is not probable that it now (1861) makes its appearance for the first time;" and another writer on the same subject in 1846, remarks, "to say that wheat is subject to the presence of *aphides*, or plant-lice, is only to state in the case of wheat what may be affirmed of almost every known produce of our soils." Neither can I admit the correctness of the other double epithet; for to such as are acquainted with it, it wears no very "formidable" aspect; and the writer of the article in the "Agriculturist," above quoted, observes, with respect to its prevalence, that "there is not much cause for concern;" and refers analogically to another species of the same family, the *Aphis fabæ* which attacks, in countless myriads, the bean crops in England, observing, somewhat quaintly, that, notwithstanding, the English "farmers do not find their bean-crops very light."

But Mr. Conger proceeds with his entomological disquisition. After describing the form and color of his louse, as "viewed through a glass," he says, "although we discovered neither eggs nor deposit of any kind, we found the insects of various ages and sizes; the young ones were without wings, or the appearance of any; those farther advanced being but partly fledged; while those of full growth were fully fledged." There is a "Natural History Society" established in Montreal. Should the eye of any member of that Society, be fortunate enough to fall on Mr. Conger's description, that gentleman will doubtless, at the next meeting of the Society, be nominated for the honor of Fellowship. Meantime I venture, with great humility, to suggest, that the *Aphis* is *viviparous* as well as *oviparous*, and that, therefore, if I am correct, it need scarcely excite much surprise that, although young *Aphides* were found, the broken egg-shells which the observer ought, he thinks, to have discovered, by the help of his "glass," were imperceptible. Again, as to the "unfledged," "partially fledged," and "fully fledged" *Aphides*, I once more, almost tremblingly, hint that while some of those interesting insects are

evidently possessed of wings, some also, the greater number, are what is called *apterous*, or wingless, and never succeed in raising those appendages. The winged females never, I believe, lay eggs, but produce their young alive.

Many other matters of interest there are connected with the family of *Aphides*, of which, by the bye, there are at least 70 species; but the limits usually assigned to a newspaper letter forbid any greater enlargement upon the subject.

I therefore, in conclusion, direct attention to Mr. Conger's lugubrious, and, I trust ill-founded, peroration; his peroration is a bane to which Professor Buckland's letter provides the antidote.

But, for the remedy? None is known, you say. Recollect, and I write the words with a feeling of profoundest reverence, that "The things which are impossible with men are possible with God." He who inflicts the disease furnishes the means of cure. He whose "great army" is "the locust, the canker-worm, and the caterpillar, and the palmer worm," can, when he sees fit, withdraw those forces, or cause them to be overcome. This *Aphis*, so much dreaded, has enemies more fatal to its existence, than are its own attacks upon the crops. The *Ant* will carry the living *Aphis*, insect after insect, to its subterranean cavern, and keep them there, stalled as it were, to feed upon their honey like excretions. The *Ichnumon* plunges her ovipositor into the body of the *Aphis*, and therein deposits her eggs, many *Aphides* being thus converted into hatching-places by a single fly. The little beetle, popularly known as the *Lady-bird*, is an insatiable devourer of *Aphides*; as also are other insects, in addition to numerous birds. So that these Plant-lice being peculiarly inactive, seldom, as I believe,—or believed till I read Mr. Conger's graphic account of their air-borne propensities, their fleeing to "parts unknown," which "parts unknown" are, I apprehend, the stomachs of their above named foes—making use of their wings, and as they are pursued incessantly and perseveringly by enemies so voracious that one single fly called *musca aphidivora* requires at least thirty *Aphides* to enable him to feel a comfortable, after-dinner lassitude, I think I may take the liberty of endorsing Professor Buckland's opinion, and of offering it to the attention of the Peterboro' Farmers, in opposition to that of Mr. Conger.

I am, sir,

Your obedient servant,

B. A.

Peterboro' August 16, 1862.

TO THE EDITOR OF THE REVIEW.—Dear Sir, —I observe that your correspondent B. A., has taxed his time and ingenuity in criticising my letter on the appearance of the Plant-Louse, published in your paper of the 15th inst. In the exercise of that right B. A., has in my opin-

ion shown a desire to indulge in a little ill-natured sarcasm which might as well perhaps have been omitted, and has attempted to draw conclusions from my letter which its language does not warrant; while the over-weening pedantry, and spirit of dictation displayed throughout his whole communication is quite in keeping with the well-known character of its author. Witness, for instance, his *excessive modesty* when he says that *he* did not, after reading Professor Buckland's letter, consider further notice of the subject necessary.

It may have been an act of presumption on my part to write, and of you to publish anything on the subject of Entomology without B.A.'s consent, but a long indulged habit of seeing, thinking and forming opinions for myself has become so strongly engrafted upon my nature that it is more than probable I shall continue to do so, regardless of whether such opinions are in unison with those of B. A. or not.

B. A. commences by saying, that "he had read the communications of Professor Buckland and myself, respecting the appearance, this year, of an insect with whose antecedents *but few agriculturists in Canada seem to be familiar*, and whose advent has, in consequence, produced a more or less inconsiderable amount of alarm," and proceeds to say that Professor Buckland's letter was so satisfactory to him, as emanating from such a source, that he scarcely thought further notice of it necessary. Why this change of mind? Let us, however, before we proceed further, examine the letter of Professor Buckland, and ascertain what those opinions were which gave to this distinguished author and critic, such unqualified satisfaction as to induce him to offer them with *his endorsement* to the farmers of Peterborough in opposition to mine, and see in what particular they differ from those I have ventured to express.

"In hops," says Professor Buckland, "the Aphis is often very destructive, but among grain its devastations are seldom of an alarming character, although in appearance the vast numbers seem *exceedingly formidable*. I have often seen fields of the horse bean in England," says Professor B. "very much affected by the Aphis, and yet a pretty good crop has been obtained,—*no doubt their presence* is generally *more or less injurious*, but nothing like Midge or Hessian-fly. *I am in hopes* that you and your neighbours will not find it *this year* so injurious in the result as present appearance may seem to indicate; as to remedy we are almost powerless, the insect appears to be a *new comer* in your part of the country."

So much for Professor Buckland's letter and opinions. In my letter I spoke of the insect as a "new and formidable looking depredator," and in my concluding paragraph said: "*what amount of damage this heretofore unknown foe may do is at this moment impossible to determine*, that it will be serious I have little

doubt."—And pray how much less has Professor Buckland said? Has he not also declared these insects to be *destructive, formidable* in their appearance, and beyond doubt, *injurious*. And yet, notwithstanding the great similarity of opinion expressed in the letters of Professor Buckland and myself, B. A., with his usual regard for truth and fairness, approves of the one and condemns the other.

But suppose for a moment that Professor Buckland's opinions—which were given on the 20th of July, before the insect had shown itself in any great force—had in some measure differed from those I ventured to express as the result of an examination made by Mr. Harvey and myself, on the 11th of August at a time when these insects were most numerous. Would it in any way have affected my statement? And were we not at that time in a better position to judge of the probable effect they would produce upon the crops than those whose examinations were made three or four weeks before at a time when the insect first made its appearance?

B. A. also questions the correctness of my description,—though he does not venture to say in what particular I have erred. In reply to this I may simply state that while I make no pretensions to the science of Entomology, I challenge B. A. or any one else who has made similar examinations, to show wherein I am wrong. My description of the insect and its operations upon the fields of grain we visited, was given precisely as we saw it, and as it then appeared, omitting entirely to notice any of the fine drawn theories of Naturalists as to its nature and habits. Leaving such of your readers as are desirous of obtaining more minute information to consult the writings of Reaumer, Kirby, Curtis, Dr. Fitch or Professor Hind, where they could find all they desired quite as well as if *reproduced* by B. A. or myself. It is true I did not fill my communication with high sounding words selected from works upon the science of Entomology. But I believe I made myself understood by that class of your readers who are most interested in the matter. And although on the occasion of which I speak, I had not the assistance of those brilliant eyes which B. A. says "assisted him in watching the operations of his diminutive *grave digger*," yet I had the assistance of two experienced and highly intelligent farmers, quite as able to judge of what they saw, and what I attempted to describe, as Professor Buckland himself, and who fully concurred in the views I expressed.

In conclusion I will give you for B. A.'s especial benefit, the following opinions of Professor Hind, whose essay on the Weevil and other grain destroyers obtained the first prize in 1857.

Professor Hind in his admirable essay speaking of the Aphis, say: "The wonderful fertility of this tribe of insects exceeds that of any known species, and elevates them to a position in the scale of pests and plagues which secures for

them the *second* if not—in many temperate climates—the *first place* among insects depredators. A few weeks is sufficient to convert a handful of these viviparous and oviparous insects into countless legions, which, taking flight, *darken the air with their numbers.*" I must also, before closing this already long letter, respectfully advise B. A. to extend his reading, and before he again ventures upon unknown ground, to understand his subject.

As for his sneer about the chances of my being offered a fellowship in the society of Natural History, he will permit me to say that it is possible my chances are quite equal to those of the *learned delineator of the insect "grave digger,"* and would be Professor of Entomology.

I am your obedient servant,

W. S. CONGER.

Peterboro, 26th August, 1862.

P. S.—Since writing the above I have seen many farmers, and regret to learn from them that the fears I expressed in my letter of the 15th inst., as to the probable damage the "Aphis," or Plant-Louse, would inflict upon the crops in this part of the country, are likely to be more than realized, and persons who at that time considered their grain uninjured, have during the last few days, while harvesting, discovered that their oats and spring wheat have suffered seriously.

Yours,

W. S. CONGER.

Peterboro', 30th Aug., 1862.

### Chinese Sugar Cane.

DEAR SIR,—In looking over the Prize List of the approaching Exhibition, I regret to notice that no prize is offered for an agricultural product now becoming one of the most important staples of the Western States, and which might, if encouraged, become a most important addition to our provincial produce and manufactures;—I refer to the *Chinese Sugar Cane or Sorghum*, which grows wherever Indian Corn may be cultivated.

I have seen it stated in late American Newspaper that in one State, either Illinois or Indiana so much has been raised of Sorghum during the present year, that the wants of the population, for Syrup, or Sugar, (or both) will not only be supplied, but that there will be a surplus for exportation. Throughout the entire west, during the year, no less than about 50,000 acres are said to have been occupied by this comparatively new plant. I have tested its growth in this Province and am convinced we could raise it to advantage as well as our neighbours in the West. Syrup and Sugar are of universal consumption, and I have no doubt every farmer who can raise Indian Corn, can raise the cane to supply his own syrup or sugar. We want the machine for crushing the cane, and the apparatus

for evaporating the sap or juice, but these can easily be produced, as they now form ordinary articles at the west. I regret that this important product of the soil has escaped the notice, or failed to excite the interest of the managers of the affairs of the Provincial Exhibition.

I beg also to refer to some agricultural machinery or implements which do not appear in the List, but which seem to me of considerable importance to farmers generally.

1. A good cheap Horse-Power for *one or two horses* for ordinary farm purposes.

2. A simple machine for sowing Lime, or Plaster by horse-power.

2. A simple but effective machine for sowing Turnip, Carrot, Parsnip, Mangelwurzel seed &c. in two drills at once, by horse-power.

The proposed erection of a Sugar Refinery in Toronto, by Mr. W. Molson, of Montreal, might, in my opinion, greatly facilitate the growth of the Chinese Sugar Cane in the County of York or the neighbouring counties, as farmers could conveniently exchange their home-made syrup for sugar, which I believe is commonly done in the west wherever there is convenient access to a sugar refinery. The sap of the Sorghum contains, I learn, about five times the amount of Saccharine found in the Maple, and the manufacture of the syrup is a rapid and simple process and from 200 to 300 gallons may be produced from an acre

I am, my dear sir,

Yours respectfully,

JAMES LESSLIE.

E. W. THOMSON, ESQ.,

President Board of Agriculture, U. C.

Toronto, 29th Aug., 1862.

### REMARKS.

[The Board of Agriculture is always glad to receive suggestions of the character of the above, and feel grateful for them. We shall be happy to receive communications from our readers who have had experience in the culture of the Sorghum, and of its conversion into syrup and sugar. The other subjects to which Mr. Lesslie refers shall not be lost sight of. It has always been the practice of the Board at the annual Provincial Exhibitions to notice and give extra prizes to articles of merit, although not enumerated in the prize list. Eds.]

### Woods at the International Exhibition.

(From the Mark-Lane Express.)

One of the most extensive and interesting of the numerous collections now on view in the International Exhibition is certainly that of the woods, sent from so many countries and climates and from far separated districts. A complete

analytical examination of these would be of the greatest importance in the interests of manufactures and commerce. The British Colonies, Asia, and Africa, North and South America, and the various European States, all contribute of their forest wealth, adapted for the many convenient purposes for which wood is in demand. Much as Iron has come into use of late years to take the place of wood for ship building, it has not yet entirely replaced it; and there is still a large, and indeed, increasing demand for wood for lining the great iron-cased war vessels which recent invention has brought into play.

In the absence of any useful work on the products of the forests of the globe, to which reference can be made, it will, we think, be found exceedingly useful to advert from time to time to the series of woods which have been collected at much trouble and cost, to be displayed to the eyes of the world at South Kensington. These specimens may not, it is true, be very attractive or interesting to the mere idler and sight-seer at the Exhibition unless per chance he be struck with surprise at the huge dimensions of some section of a monarch of the forest, the growth of several hundred years; the great length of some planks, like those of Western Australia and Tasmania, shown in the gardens of the Royal Horticultural Society; or the picturesque timber trophy of Canadian woods, erected in the north-eastern transept, towering upwards to the roof. But, as indications of the soil, as mementoes of indigenous wealth, open to the axe of industry as materials for the use of the skilled mechanic and artificer, these collections of wood open up one of the most instructive fields for investigation, and will diffuse much that will supply thought hereafter. Capt. Fowke, R. E., who has already published some most interesting results of experiments on the strength and properties of colonial and other woods shown at the Paris Exhibition in 1855, is now conducting at the South Kensington Museum a daily series of tests on many of the woods exhibited; the published results of which will be of great importance.

Of the British colonies, Canada stands out most prominent in the collection of woods, and the colony on this occasion, with limited funds at command, has done well to confine itself chiefly to a noble display of her vegetable and mineral treasures. There are several collections of wood shown; and although they are more characterized for utility than for beauty, yet they are such woods as could not be done without; and our Australian and tropical colonies come in, too, with furniture and cabinet woods generally. It affords us much gratification to learn that an effort is making on the part of the representatives of the various colonies to establish by colonial aid, a permanent museum of colonial products; and from the unanimity with which the movement has been originated, there is every probability of its success, and of the most valuable collection now on view being re-

tained in tact. The usefulness of such a museum to the manufacturer, the artisan, the emigrant, and indeed to all interested in the progress of our colonies, will be generally admitted; and while France with but five or six colonies has long maintained such a colonial museum, it does seem singular that Great Britain, with its fifty important colonies, spread over every part of the globe, should not long since have had such a collection, instead of being obliged every five or ten years to have to go to enormous expense in forming collections which immediately after are sold and disposed of and lost to the world.

New Brunswick, considering her forest resources, has not produced so good a display of woods as she might have done, although there are some very fine ornamental illustrations. British Columbia and Vancouver have done as well as could be expected from their great distance and the expense of transit of large specimens—the planks and sections of the Douglass pine and other giants of the forest indicate one of the sources of colonial wealth.

The Australian colonies have all come out well in a display of their woods—and it is hard to award the palm. New South Wales, Queensland, Victoria, Tasmania, Western Australia, and New Zealand, all show very fine specimens of their woods in all stages—rough, polished and manufactured. Ceylon shows some of her beautiful furniture woods and their applications. India has not done so much as she might have done, but she is circumscribed for space to exhibit the noble sections of wood lying at Eyfeshouse, the India gallery being chiefly occupied with works of art more attractive to the general public. Mauritius, St. Helena, and a few other small colonies have a fair display of woods; and Natal stands as the representative of Southern Africa, and proves that there are some useful woods to be found in that quarter.

Passing to the West India group of colonies, we find that great efforts have been made on this occasion to develop its woods and bring them into public notice, and the beneficial result of this effort cannot fail to be felt. The ornamental woods of Jamaica, of Trinidad, and British Guiana have taken the public by surprise and the cabinet work made of them is of singular beauty, and we do not wonder that these woods have been highly commended and rewarded by the juries. British Honduras, Dominica, and some of the smaller islands have also turned their attention, we hope with profit, to a collection of their indigenous woods, with information of their properties and uses. The valuable squared logs of mahogany shown in the Haytian court, the woods of Europe, Algeria, and the French colonies, are all the evidences of the dormant wealth yet available, although settlement and the progress of population are making greater havoc among the forests than the forethought of individuals or governments is replacing by replanting.

### On the Cultivation of Wheat in Canada. and on the Season of 1862.

In the July and August numbers of this Journal we noticed the "Home Manufactures of Canada," and the "Use we make of our Mineral Resources," we now propose to devote a few pages to the Industry of the Soil, and the Manufactures which are dependent upon a constant and cheap supply of grain. In collecting material for this subject, the extraordinary fluctuations in the production of wheat in Lower Canada came so prominently into view, when contrasted with the rapid and steady increase in Upper Canada, that we were led to devote more space to this important subject than would appear to belong to the pages of this Journal, and our notice of "the Cultivation of Wheat in Canada and of the season of 1862," has swelled to a far greater extent than was anticipated, when a mere introduction to the condition of different manufactures in the Province, dependent upon a supply of rye, barley, wheat, and Indian corn was in contemplation.

There are many important questions which require solution, with respect to the cultivation of Wheat in Canada.

Two facts are patent to all from the results of the last census. These are:—

First; The cultivation of wheat is rapidly diminishing in Lower Canada, and the quantity raised does not amount to one-half what is required to feed her population, assuming that each man, woman and child consumes five bushels only per annum.

Second; The cultivation of spring wheat is rapidly increasing in Upper Canada, and more than twice the quantity of land is devoted to spring wheat than to fall wheat.

With regard to the first statement—namely the diminution in the cultivation of wheat in Lower Canada—we find that section of the Province formerly exported a very considerable quantity of wheat, the produce of her own soil. The following table shows the exports of wheat from Quebec between 1793 and 1802, inclusive;

| Year.      | Wheat, bus. | Flour. | Biscuit, cwt. |
|------------|-------------|--------|---------------|
| 1793.....  | 478,900     | 19,000 | 9,800         |
| 1794.....  | 414,000     | 13,700 | 15,000        |
| 1795.....  | 395,000     | 18,000 | 20,000        |
| 1796*..... | 3,106       | 4,300  | 3,800         |
| 1797.....  | 31,000      | 14,000 | 8,000         |
| 1798.....  | 92,000      | 9,500  | 12,000        |
| 1799.....  | 129,000     | 14,400 | 21,500        |
| 1800.....  | 217,000     | 20,000 | 25,000        |
| 1801.....  | 473,000     | 38,000 | 32,000        |
| 1802.....  | 1,010,033   | 28,300 | 22,051        |

In 1802 the population of Upper Canada did not exceed 60,000 souls, and there is no reason to suppose that that part of the Province contributed much wheat for export previous to 1802.

\*The exportation of wheat was prohibited this year, in consequence of the bad crops of 1795.

The frontier States of the Union did, no doubt, contribute flour and wheat "in casks." We will therefore strike out from the above table all the exports of flour and biscuits, and credit them to the frontier States and Upper Canada, amounting to 855,500 bushels wheat, and 169,451 cwt. biscuit, from 1793 to 1802, a period of ten years.

With these deductions, the total quantity of wheat of Lower Canada growth exported between 1793 and 1802, amounted to 3251,139 bushels, or at the rate of three hundred and twenty-five thousand bushels per annum.

The quantity of wheat raised in Lower Canada in 1827, '31, '44, '51 and '60 was as follows, showing no increase, but, in proportion to the population, an extraordinary and indeed alarming decrease:

| Year.      | No. of bushels. |
|------------|-----------------|
| 1827 ..... | 2,931,240 (1)   |
| 1831 ..... | 3,404,756       |
| 1844 ..... | 942,835         |
| 1851 ..... | 3,045,600 (2)   |
| 1860 ..... | 2,563,144 (3)   |

The quantity required to feed the population of Lower Canada, at five bushels per head, the usual allowance, is 5,553,320 bushels. Hence the people of Lower Canada, if they consumed wheat after the manner of their forefathers, would require an importation of not less than 2,990,206, or nearly three million bushels.

Nor is this decrease compensated by the production of other kinds of grain in due proportion. The total amount of barley, rye, peas, oats, buckwheat and Indian corn, raised in 1851, amounted to 12,147,000 bushels, and in 1860 to 23,534,903 bushels; † an increase of 11,387,533 bushels—not in fact even doubling in ten years, while during the same the population increased from 890,271 to 1,110,664 souls.

The comparison between Upper and Lower Canada stands thus in relation to population and the production of the following articles:

|                                                                   | Upper Canada. | Lower Canada. |
|-------------------------------------------------------------------|---------------|---------------|
| Population, 1851 .....                                            | 952,004       | 860,261       |
| " 1861 .....                                                      | 1,306,091     | 1,110,664     |
| Wheat crop of 1860, bus 24,620,425                                |               | 2,563,114     |
| Indian corn, rye, oats, }<br>barley, buckwheat }<br>and peas..... | 36,122,340    | 23,534,903    |

Total bus. grain in 1860.....60,742,765 26,098,017

Proportion of grain produced in Upper Canada to each inhabitant, 43 bushels.

Proportion of grain produced in Lower Canada to each inhabitant, 23 bushels.

The change is astonishing which has taken place in Lower Canadian husbandry during the

(1) Bouchette. (2) Census 1851-'2. (3) Mr. Galt's Budget Speech.

† Mr. Galt's Speech.

last half-century, and is certainly worthy of special study, and even of the attention of the Government. When a province which once was a large exporter of wheat becomes incapable, under her present system of husbandry, of raising one-half of the quantity of a staple product of human food necessary for home consumption, questions of much moment arise. Does it result from a change in the climate from insects destructive to wheat crops, exhaustion of the soil, or bad farming practice? No doubt, more or less, from all of these causes united; but we must chiefly look to the manner in which the soil is cultivated, and the practice prevailing in Lower Canada, for the solution of this problem.

Turning now to Upper Canada, we find the following encouraging statistics:

| Year.      | Wheat produced in bush |
|------------|------------------------|
| 1842 ----- | 3,221,991              |
| 1848 ----- | 7,558,773              |
| 1851 ----- | 12,674,503             |
| 1860 ----- | 24,620,425             |

In some counties in Upper Canada the cultivation of wheat is progressing with extraordinary rapidity (too rapidly, we fear, for good husbandry), as the following comparative table, showing the produce of the United Counties of York, Ontario and Peel for the years 1848, 1850, 1851 and 1860, will tend to show:

| Produce. | 1848.     | 1850.     | 1851.     | 1860.     |
|----------|-----------|-----------|-----------|-----------|
| Wheat    | 1,451,384 | 2,038,676 | 2,362,932 | 3,469,002 |

The United Counties of York, Ontario and Peel produced in 1860, as much wheat as Lower Canada in 1831, and nearly one million more bushels than Lower Canada in 1860.

We would remind those among our readers who are inclined to the view that the Wheat Midge and the Hessian fly are pre-eminently destructive in Lower Canada, that by the use of early-ripening seed, draining, and improvement in farming practice, the "fly" has been overcome in many parts of Upper Canada, and there is no fear that with the adoption of well-known artifices the ravages of these destructive insects will be held in check. And why we ask, might not the same artifices have been employed in Lower Canada, which have proved so successful with us! Probably an answer will suggest itself when we compare the number and circulation of the newspapers published in the French language, with the number and circulation of the same means of diffusing information in the English tongue in Upper Canada. It is a question, we submit, which might reasonably engage the attention of the Minister of Agriculture, whether an enquiry should not be set on foot to obtain information respecting the cultivation of wheat in Lower Canada, and the best means of circulating a knowledge of the most successful remedies against the ravages of the Midge and Hessian fly, which are so generally instanced, and, we think, most erroneously, as the ineffic-

able destroyers of the wheat crops in Lower Canada, whose wide-spread devastations it would be vain to attempt to arrest.

The present year has been remarkable for the infinite number of insect-pests which have infested the wheat crops, but fortunately without, as far as we can learn, occasioning any wide-spread damage.

The insect which created the greatest alarm at one time was an *Aphis*, a very common and most prolific creature, whose powers of multiplying itself almost surpass belief, and furnish us with one of the most astonishing marvels of insect life, out of the vast number by which we are daily surrounded. If the reader has noticed the extremities of the shoots of currant bushes during the latter part of August and the beginning of September of the present year he will have observed, no doubt, a vast number of green and brown insects feeding on the leaves, causing them to curl up, and often assume a dark or a bright colour according to the stage of insect growth. The green and brown insects are *Aphids*, similar to those which were found in such infinite numbers upon the succulent parts of the wheat and many other plants where they are not commonly observed during the early part of the summer.

The *Aphis*, or Plant Louse, is a name given to a very extensive genus of insects, whose destructive habits and wonderful productiveness make the study of their history especially interesting to farmers and gardeners. Certain species of *Aphids* affect different plants. Dr. Fitch describes twenty-eight species, which feed upon the juices of Indian corn, the pear, apple, cherry, and a number of other trees. In the collection of the British Museum no less than 326 species of this insect are described, and it is worthy of notice that almost every species of plant has its own peculiar *Aphis*. The Hop-fly and Bean-dolphin have occasioned immense destruction in Britain. In 1802 the hop duty fell from £100,000 to £14,000 on account of the great increase of the *Aphis*. When the *Aphis* has been absent the duty has risen to £500,000. This insect is well named the *APHIS* or *EXHAUSTER*. They are so prolific that one individual may become the progenitor of one quintillion in the 10th generation. As many of our readers may not be quite familiar with the vast number represented by the word 'quintillion,' some details may be useful. Professor Owen shows in his lectures on 'Comparative Anatomy,' that the *Aphis lanigera* produces each year ten viviparous broods, and one which is oviparous, and each generation averages 100 individuals:—

|                |                                         |
|----------------|-----------------------------------------|
| 1st Generation | —1 <i>Aphis</i> produces                |
| 2nd "          | —100 One hundred                        |
| 3rd "          | —10,000 Ten thousand                    |
| 4th "          | —1,000,000 One million                  |
| 5th "          | —100,000,000 One hundred m.l.           |
| 10th "         | —1,000,000,000,000,000 one quintillion. |

The Aphids which appear in Spring are exclusively females, no males being found till the Autumn. It is not necessary for the young females produced during the Summer to pair with a male; yet these females go on producing each 25 day of living young ones, all of which become in a short time as fertile as their parent.

It does not come within the province of this Journal to describe more in detail the habits of these insects, but to those of our readers who are interested in this curious subject we may refer them to the following accessible works, in which they will find much valuable information:—

1. First and Second Report on the Noxious, Beneficial, and other Insects of the State of New York. By Asa Fitch, M.D.
2. Harris on Insects. New Edition.
3. The Farmers' Encyclopædia. By Cuthbert Johnson.
4. The English Cyclopædia.
5. Stephens' Farmers' Guide.

The question naturally arises, why were these insects so numerous during the present year? The cause is to be traced, very probably, to the extraordinary dryness of the spring months of 1862.

The Aphis multiplies much faster in a dry season than in one which is humid; like the red spider, and many other destructive insects, it is fond of a warm and dry atmosphere. The month of May was extremely dry, and the quantity of rain recorded at the Toronto Observatory was only one third of the average which has fallen in that month for twenty two years.

The month of June was also remarkably dry, the amount of rain which fell reaching only one third of the average of twenty-two years, and it was the driest June which has occurred during the entire period in which observations have been made at Toronto. Fortunately for the wheat and other crops July was extremely wet, having nearly double the average fall of rain, so that not only were the crops pushed forward by the unusual moisture of the earth, but an innumerable host of insects were washed off the leaves of the growing crops by the heavy and continuous fall of rain. By the most unusual and providential fall of rain in that month the multiplication of the Aphis was arrested and the crops of the country saved. It will be noticed throughout Canada, that in general the fall wheat has been harvested at an average time of the year—the spring crops are later than is common with us. The fall wheat was sustained during the long drought by the great amount of moisture in the soil at the advent of spring, from the excess of snow and rain which fell in February and March. In March we had one inch more rain and nearly ten inches more snow than the average of twenty-two years.

The retardation in the growth of spring crops arising from the dryness of May and June has probably been of immense value to the country

in destroying the Midge. That this insect was very abundant in many parts of Canada during the present year there is no reason to doubt; observations in many different quarters have recorded its presence in infinite numbers, but the fly appeared before the wheat was ready to receive it, and its eggs were deposited where there was no suitable food for the young worms when hatched; myriads would consequently die for want of food, and therefore we may look upon the unusually dry spring of 1862 as having been a blessing of incalculable value to the Canadian Farmer by destroying one of the worst and most widely distributed enemies of his wheat crops. The maggots of the Midge were also seen in vast numbers in the fall wheat, but generally it was too far advanced for them to injure it to any considerable extent. The fall wheat was suddenly pushed forward by the July rains (which at the same time destroyed the Aphis) and the Midge could not penetrate the chaff or sheath to deposit its eggs, or if it succeeded in penetrating the germ the young worms were hatched after the grain had been formed. Although this year has been one of most exceptional character in relation to the distribution of snow and rain, yet when viewed in the proper light it will afford a striking illustration of that wise and merciful beneficence which disposes and adjusts all things for some excellent purposes, which do not appear to our eyes until the object for which the disposition was made is attained, and sometimes not even then.

The following table from the records of the Provincial Observatory has been kindly furnished by Professor Kingston—an examination of its contents will show the extraordinary character of May June and July of the present year.

|                         | May.  | June. | July. |
|-------------------------|-------|-------|-------|
| Mean Temperature 1862   | 52.17 | 60.52 | 66.70 |
| Average for 22 years .. | 51.39 | 61.36 | 66.85 |
| Difference from average | x0.78 | —0.1  | —0.15 |

|                         | Inches. | Inches. | Inches. |
|-------------------------|---------|---------|---------|
| Depth of Rain, 1862 ..  | 1.427   | 1.007   | 5.344   |
| Average of 22 years ..  | 3.241   | 3.100   | 3.490   |
| Difference from average | —1.814  | —2.093  | x1.854  |

|                         | Days. | Days. | Days. |
|-------------------------|-------|-------|-------|
| No. of Rainy days 1862  | 8.0   | 10.0  | 15.0  |
| Average of 22 years ..  | 11.3  | 11.9  | 10.0  |
| Difference from average | —3.3  | —1.9  | x5.0  |

May, 1862, was mild, and extremely dry, but it was thrice surpassed in that respect: it only records one-third of the average depth of rain.

June, 1862, was comparatively cold and extremely dry, the depth of rain recorded only reached one-third of the average; it was absolutely the driest June during the last 23 years.

July, 1862, was comparatively cold and extremely wet, showing nearly the double the aver-

age depth of rain, it was only once surpassed, viz. in 1841 when the depth recorded amounted to 8.150 inches.

A comparison of the foregoing with the corresponding months of the several years may be made by referring to the comparative tables that accompany the monthly reports for May, June, and July, 1861, published in the *Canadian Journal*.

A glance at the following table will show how dependent the prosperity of the country is upon a good harvest. It will be seen that the difference between the agricultural exports of 1856 and 1857 amounted to more than six millions of dollars, and that our exports last year exceeded those of 1857 by ten millions of dollars.

*Table of the absolute value of all Agricultural products exported, exclusively of Canadian growth, for the years 1853 to 1861, inclusive.*

| Year.      | Value of Ag. Exports | Year.      | Value of Ag. Exports |
|------------|----------------------|------------|----------------------|
| 1853 ..... | \$8,032,535          | 1858 ..... | 7,904,400            |
| 1854 ..... | 7,316,160            | 1859 ..... | 7,339,798            |
| 1855 ..... | 13,130,399           | 1860 ..... | 14,259,225           |
| 1856 ..... | 14,972,276           | 1861 ..... | 18,244,631           |
| 1857 ..... | 8,882,825            |            |                      |

In our next issue we shall endeavour to exhibit the use we make of a considerable portion of our rapidly increasing grain crops and show how closely dependent many important manufactures in Canada are upon a good harvest.—*Journal of Board of Arts and Manufactures.*

## A Drop of Rain-Water.

BY CUTHBERT W. JOHNSON, ESQ., F. R. S.

We are often, but erroneously, said by foreigners to be far too attentive to the weather—that it is too often the leading topic of our conversation; but if the remark had any foundation it is hardly a matter of surprise, as we have more reason than most nations for having our thoughts thus directed; we are more dependent upon the weather for our food than those blessed with more certain seasons; our corn, our vegetables, our fruits, are all natives of other and warmer lands; we can only preserve by very great care and skill what nature spontaneously produces in more southern soils, and under a more serene climate. We are all, therefore, whether gardeners or agriculturists, deeply interested in atmospheric transitions in temperature, and in the degree of moisture to which our plants are exposed. It is but rarely, however, that we inquire of the *origin* and *history* of the meteorological phenomena which encircle us. The research might, however, be attended with more profit than we may at first suspect. It is with that conviction that I propose in this and a subsequent paper to endeavour to trace the history of a drop of rain-water.

The *origin* and *progress* of a drop of rain water is a history of many things which relate not only to our comfort and enjoyment, to the growth of the vegetable world, but to our very existence. We do not commonly inquire about such matters; we have always been used to see the rain descend; there is nothing novel about it, to cause us to search as to its history—why it falls upon our fields, whence it comes, or where that water proceeds in its course when it disappears in the earth from our sight? We do not engage in such examinations, because the phenomenon is neither novel nor startling; the fall of a meteoric stone arouses more attention, although we can neither discern its origin nor its usefulness, than all the rain-drops, which we well know spread the oil of fatness so continuously over our fields. Could our lot have been cast in a totally rainless district, like that of the Chincha or Guano Islands, on the Peruvian coast, our wonder would have been considerably excited when first placed in a shower of rain—our inquiries about its origin more fervid, our gratitude to its great Author more deep. It may be more useful, then, if we travel together with an imaginary inquirer of this kind, who has everything to learn with regard to a drop of rain-water, and is anxious to find its origin, its nature, and why and whence it disappears or evaporates.

The size, shape, the composition of a drop of rain seems to be naturally the first portion of our inquiry. Its size varies: from the very smallest, say 1-24th to about  $\frac{1}{2}$  of an inch in diameter; its shape is spherical. An early reflection presents itself when we are considering the size of a drop of rain,—the beneficence of its Divine Architect in adapting the weight of those rain-drops to the wants and safety of His creatures. Falling as they do from a great elevation, they descend with a force which, had they been considerably larger, would have spread death and destruction in every shower. We all know the painful effect produced upon our heads by a rapidly-descending current of water, or when a few small drops of rain are congealed together by a low temperature as they descend from the clouds, and hailstones formed. In our driest summers, it is true, we may desire, in figurative language, “*torrents*” of rain upon our languishing crops; but no one wishes to receive rain-drops as large as turnips, or rain falling in columns. A prayer for a hailstorm was perhaps never yet uttered. We see, then, that even the rain-drops were weighed by their Divine Author, their gravity adapted to the powers and good of His creatures, and the bed of earth on which they were to descend and fertilize. The mean annual fall of rain on the entire surface of the earth is estimated at about five feet (Maury, *Phy. Geo. Sea*, 207); but the amount of the average annual fall of rain varies, however, widely in different countries, from the districts

of the Andes, where the rain rarely ceases, to those not a hundred miles distant, around Lima where rain is almost unknown.

In our quarter of the globe, the annual rainfall varies with different countries, altitudes, and exposures to moist westerly currents. At Madrid, which is placed on an elevated plateau, the annual rainfall is only about 10 inches. At Coimbra, in Portugal, a fall of more than 200 inches has been recorded. Extraordinary rainfalls have occurred occasionally in the South of Europe. On October 25, 1825, 32 inches fell at Genoa, and October 9, 1827, at Joyeuse, in the South of France, 31 inches fell. In the East Indies 13.06 inches fell at Mahabuleshwur, September 2, 1833; but 11 or 12 inches is not rare. In July, 1840, 134.42 inches fell at that station. At Bombay, July 1, 1844, 7.44 inches fell in twenty-four hours, 2 inches falling in seventy minutes (*ibid*, p. 366). In England our rainfalls do not nearly approach amounts like these. Mr. E. J. Lowe has recorded the most rainy months and days at Beeston, near Nottingham, from 1843 to 1857:—

## MOST RAINY MONTHS.

|                       | Inches. |
|-----------------------|---------|
| 1852, November .. ..  | 7.0     |
| 1252, September .. .. | 5.3     |
| 1849, September .. .. | 5.0     |
| 1847, May .. ..       | 5.0     |
| 1853, June .. ..      | 5.0     |

## MOST RAINY DAYS.

|                          |       |
|--------------------------|-------|
| 1843, August 9 .. ..     | 1.095 |
| 1846, October 19 .. ..   | 1.300 |
| 1847, May 8 .. ..        | 1.645 |
| 1848, June 18 .. ..      | 1.055 |
| 1848, September 28 .. .. | 1.155 |
| 1849, July 25 .. ..      | 1.084 |
| 1850, July 24 .. ..      | 1.106 |
| 1851, July 26 .. ..      | 2.063 |
| 1852, September 6 .. ..  | 2.044 |
| 1853, August 17 .. ..    | 1.502 |
| 1855, July 14 .. ..      | 1.060 |
| 1857, June 30 .. ..      | 1.590 |
| 1857, August 13 .. ..    | 8.010 |

In our country, the smallest rainfall is in Essex, which hardly averages 20 inches. The largest is in the westerly counties, where it ranges from 35 to 46 inches. On some of the mountains in Westmorland 108 to 148 inches have been recorded in one year.

## ITS ORIGIN AS VAPOUR.

Having noted the fall of rain—seen it descend from the clouds—the next portion of our inquiry is. How did that rain water get into the atmosphere? We need hardly be reminded that it was by the evaporation of water from the earth's surface. "To evaporate," observes Maury, in his valuable work on the Physical Geography of the Sea, "water enough annually

from the ocean to cover the earth to a depth of five feet with rain-water, to transport it from one zone to another, and to precipitate it in the right places at suitable times and in due proportions, is one of the grand offices of the atmosphere." This water is evaporated chiefly from the torrid zone. Supposing it all to come thence, to raise as high as the clouds, and to lower down again, all the waters in a lake sixteen feet deep, three thousand miles broad, and twenty-four thousand long, of the annual business of this invisible machinery. Well may we exclaim, What a powerful engine is the atmosphere! And how nicely adjusted must be all its cogs, and wheels, and springs, and compensations, that it never wares out, or fails to do its work at the right time and in the right way! "According to Laidly," adds Maury, "the evaporation at Calcutta is about 15 feet annually; between the Cape of Good Hope and Calcutta it averages in October and November, nearly three-quarters of an inch daily; between 10 and 20 degrees in the Bay of Bengal it was found to exceed an inch daily. The South Seas then should supply the atmosphere with watery vapour, while the northern hemisphere condenses it. We should therefore have more rain in the northern hemisphere. The rivers tell us that we have, for the great water courses of the globe, and half the fresh water in the world, are found on our side of the equator. The rain gauge also tells us the same story. The average fall of rain in the north temperate zone, according to Johnstone, is 36 inches: he gives but 26 inches in the south temperate. The observations of mariners corroborate this conclusion. Rains, fogs, thunder, calms, and storms, all occur much more frequently, and more irregularly on this side, than they do on the other side of the equator.

Let us begin our examination by finding out the ordinary amount of vapour present in the air, and with what gases it is mixed. The composition of the atmosphere, at a mean temperature and pressure, is as follows:—

## By measure. By weight.

|                      |      |       |
|----------------------|------|-------|
| Nitrogen gas .. .    | 77.5 | 75.55 |
| Oxygen gas .. .      | 21.0 | 23.32 |
| Aqueous vapour ..    | 1.42 | 1.03  |
| Carbonic acid gas .. | 0.08 | 0.10  |

Whoever wishes to see that aqueous portion of the atmosphere made apparent to his senses, need only to introduce a glass of very cold water into a warm well-tenanted room—the vapour of its atmosphere is immediately condensed on the glass. It is not as is commonly said, the heat of the air, but its warm aqueous vapour, that strikes, that is condenses upon the glass.

The state in which water exists in the atmosphere seems now pretty well determined. It was formerly supposed, by the majority of philosophers, that it was in a state of chemical combination with the atmospheric gases; but later researches seem to show that it is in a state of

steam. Saussure long since had shown that the amount of steam existing in a given space and temperature is the same, whether the space be free from or filled with air; and then Dalton distinctly proved that the vapour of water mixed with air, or other gas permanent over water, differs in no respect from pure steam, and is subject to the same laws. The aqueous vapour of the air constitutes, in his opinion, a distinct and independent atmosphere, the elastic force of which forms at different temperatures different proportions of the elastic force of the whole. For example, at the temperature of 95 deg. it gives to air 1-50th of its elasticity. According, therefore, to this view, which is confirmed by the experiments of Gay Lussac and others, a volume of air, or gas, at any temperature, saturated with moisture, contains as much steam as would exist, at the same temperature, in a vacuum of the same extent.

The insensible vapour in the air we may then conclude is merely mechanically mixed with the atmospheric gases; there is no chemical combination. It is the diffusion of water in the state of steam, produced by the evaporation from the earth's surface. This evaporation is hardly ever interrupted; it continues very often even when rain is falling, or the ground covered with snow—under the burning sun of the equator, or in the eternal ice of the arctic regions, it still proceeds. It is, indeed, remarkable, as the Rev. L. Jenyns observes ("Meteorology," p. 164), that evaporation still goes on when water is frozen, the same as when it is liquid: even the most intense cold is insufficient of itself to put a stop to it. This circumstance often strikes persons with astonishment who witness it in its effects without being aware of the true cause. They see a fall of snow gradually waste—if light, wholly disappear—or a block of ice sensibly diminish during the continuance of a frost, especially if the wind blows tolerably fresh from some point towards the north, without the least sign of liquefaction on the surface. And they perhaps naturally enough wonder what has become of it. Sometimes also in deeper snows the surface becomes curiously grooved or channelled, by the wind acting unequally upon it, and thus promoting unequally the evaporation. This phenomenon is best observed around the trunks of trees, and near the interstices of palings, or wherever a stream of air acquires an increased force in a particular direction. There is every reason to conclude with Dr. Prout, that the quantity of vapour thus formed from snow and ice is precisely equal to what would be evaporated from water itself, provided water could exist as a fluid before the temperature at which it is congealed.

The amount of water in the air, from an average of seven years' observation at the Greenwich observatory during each month of the year, has been given by Mr. J. H. Belleville, in his "Manual of the Thermometer."

In the following table, column I, gives the

mean weight, in grains, of vapour in a cubic foot of air at 9 o'clock, a.m., and column II. the amount at 3 o'clock, p.m., Column III. gives the mean addition of vapour required for complete saturation of a cubic foot of air at 9 o'clock, and column IV. the amount needed at 3 o'clock.

|            | EXISTING AMOUNT. |        | DEFICIENCY. |        |
|------------|------------------|--------|-------------|--------|
|            | I.               | II.    | III.        | IV.    |
|            | 9 A.M.           | 3 P.M. | 9 A.M.      | 3 P.M. |
| January..  | 2.70             | 2.84   | 0.17        | 0.30   |
| February.. | 2.58             | 2.72   | 0.25        | 0.62   |
| March...   | 2.77             | 2.85   | 0.40        | 1.05   |
| April....  | 3.26             | 3.37   | 0.68        | 1.41   |
| May.....   | 4.02             | 4.06   | 1.10        | 2.04   |
| June.....  | 4.71             | 4.78   | 1.45        | 2.42   |
| July.....  | 5.07             | 5.26   | 1.50        | 2.27   |
| August...  | 5.00             | 5.07   | 1.18        | 2.27   |
| September  | 4.66             | 4.77   | 0.73        | 1.93   |
| October..  | 3.96             | 4.01   | 0.35        | 1.08   |
| November   | 3.27             | 3.42   | 0.22        | 0.55   |
| December.  | 2.78             | 2.89   | 0.17        | 0.37   |

The amount of water which the air contains<sup>d</sup> let us remember, increases with its temperature. The mean relative humidity of the air, Mr. Belleville observes, is greater at 9 a.m. than at 3 p.m.; the mean quantity of vapor in this time actually *increases*, but as the increase is *not* in proportion to the increase of *temperature* in the same interval, the air is relatively drier.

November, December and January are the months when the air is most frequently saturated with vapour. As Spring advances the air becomes warmer, and the point of saturation further removed. A cubic foot of atmospheric air, when saturated with water, at the temperature of 66 degrees, contains only about eight grains of water. Dalton calculated that the medium quantity of vapour held in solution at once in the atmosphere may amount to about one seventieth of its bulk.

That vapor we have seen is mainly supplied by the evaporation of the surface of the ocean; but the land contributes a large proportion: the vegetable and animal worlds do the same. First as to the portion yielded by the land, the amount of water evaporated from its surface has been examined by various experimentalists. Schubler conducted his trials on a small scale, with different earths exposed in trays to the sun and winds (*Journal R. A. S.*, vol. i. p. 177). He found that the difference in the evaporation from the surface of different earths was not so great as might have been anticipated. He determined that when a given surface of calcareous sand lost by evaporation during four hours 146 parts, an equal extent of fine garden-mould lost 143 parts, some black turf soil 128 parts, and two specimens of clay soil each lost 123 parts.

Some years after Schubler's experiments, Mr. Dickenson (*ibid*, vol. v. p. 151) examined the amount of the annual evaporation from the

Chalk soils of Hertfordshire. The following were some of the results he obtained —

|                          | 1842. | 1843. |
|--------------------------|-------|-------|
| Depth of rain in inches. | 26.43 | 26.47 |
| Evaporation.....         | 14.7  | 18.37 |
| Filtration .....         | 11.76 | 8.10  |

In the same years, on the limestone soils of Yorkshire, Mr. C. Charnock obtained the following results (*ibid*, vol. x., p. 517):—

|                          | 1842. | 1843. |
|--------------------------|-------|-------|
| Depth of rain in inches. | 26.11 | 24.9  |
| Evaporation.....         | 21.56 | 26.11 |
| Filtration.....          | 4.55  | 4.28  |

It is noticeable from these trials how much greater is the evaporation from the limestone than from the chalk; and how much less the drainage. The wind produces a far more considerable amount than the mere heat of the sun. The marine-salt makers, who expose sea-water, in very shallow ponds to the action of the atmosphere, are well aware how much faster the Summer breezes evaporate the water than the sun on a still day; every washerwoman is aware of the same fact. Mr. Charnock experimentalized upon this question; and found that—

|                                                                                                  | 1842. | 1843. |
|--------------------------------------------------------------------------------------------------|-------|-------|
| The annual evaporation from }<br>water to both the sun }<br>and the wind was in }<br>inches..... | 33.61 | 34.17 |
| From water exposed to the }<br>wind, but shaded from the }<br>sun .....                          | 22.48 | 22.7. |
| From a drained soil.....                                                                         | 21.56 | 20.11 |
| From a soil saturated with }<br>water.....                                                       | 30.02 | 31.19 |

But it is not only the surface of the earth and its waters from whence the insensible moisture of the atmosphere is derived. Plants contribute copiously, too, to the supply. It is certain that plants of all kinds exhale moisture in large proportions. Mr G. Philips (*Joar. R. A. S.*, vol. vii., p. 306) found that the polyanthus, placed in a pot of earth, between the 23th of February and the 14th of April, 1845, evaporated 2.01 grains of water daily for every square inch of surface of its leaves, the mould 10.8 grains for every inch of surface; he found that a fine day, with sun and wind, always promoted evaporation, while a dull, cold day always retarded or stopped it. The evaporation from the leaves of a potato, under similar circumstances, was much less, being at the rate of only 1.4 grains per day for each square inch of surface. The transpiration of moisture from plants increases progressively from March to August, after which period it declines. It is the most copious from sun-rise till noon, after which hour it lessens. Other plants emit moisture at a much greater rate than the polyanthus or the potato. Hales found that the sunflower transpired, in July and August, 15

grains of water from every square inch of its surface; a cabbage, under favorable circumstances, has been found to emit, daily, water equal to its own weight.

Need we attempt to calculate the enormous amount of aqueous vapor which the vegetable world thus contributes to our atmosphere? the whole covering of our Emerald Isles pouring in an incessant stream of moisture; the vegetation of all lands contributing their portion. The dense steaming forests of the equatorial regions adding perhaps the largest amount in a given space, enormous, though insensible streams, rivalling in their weight of water those of the Amazon and the Mississippi. From the vegetation of the whole world, in every clime, in every soil, and at every altitude, from the level of the sea up to the lines of eternal snow, by day and by night, is this out-pouring going on; no winds prevent its continuance, by no change of temperature is this invisible stream of watery vapor entirely stayed.

But the emission of vapor upon the air by the surface of the earth, its waters, and its vegetation, are not the only sources of the supply of atmospheric moisture. All animals contribute a considerable share. As I have elsewhere had occasion to remark, the evaporation from the surface and from the lungs of animals is very considerable; it varies, however in different species and individuals. Cruikshank calculated it from his experiments to average about 7 pints in a man, during the 24 hours; Lavoisier and Seguin made it amount to only  $3\frac{1}{4}$  pints, the maximum being 5lbs, the minimum  $1\frac{1}{2}$ lbs. They calculated that, in every 18 parts of water thus evaporated, 7 parts were from the lungs, and 11 from the skin. Its amount is increased by drink, but not by solid food. Its minimum amount is immediately after a meal, and in close, foggy weather: it attains its maximum during digestion. It is, as might be expected, the most considerable in warm and breezy weather, in hot climates, and after great exercise. This is indicated by the enormous quantity of liquid consumed by those who labor under such circumstances; the daily 14 pints of beer, the 24 pints of cider allowed to the reapers (*Jour. R. A. S.*, vol. xiv., p. 445); and by the 30 pints of porter swallowed by the London coalwhippers—an amount which is often unequal to the loss they sustain by transpiration. The evaporation from labourers in certain situations, is, in fact, enormous. Dr. Southwood Smith made some observations upon the men employed in filling and emptying the Phoenix Gas Works. These men are thus engaged twice a day. On a foggy day in November, when the temperature of the external air was 39 degrees, the greatest loss of weight by these men in an hour and a quarter, was 2lbs. 15 oz.: and the average of eight men was 2lbs. 1 oz. On a bright day in the same month, when the temperature of the surrounding air was 60 deg., the greatest loss

of weight was 4lbs. 3 oz., the average loss being 3lbs. 6 oz. On a bright, clear day in June, the greatest loss sustained in the hour, by a man who had worked in a very hot place, was 5lbs. 2 oz.; the average of all, 2lbs. 8 oz.

Such are the chief sources of the vast fountains of vapor which replenish the atmosphere with the water that we shall presently trace becoming visible to our senses, in clouds, in dew, and in the rain drop. The atmosphere in which we are enveloped, and in which, and by which we live, is indeed, full of marvels abounding with evidences of design, and the benevolence of its Creator. It is such testimonies that our readers may profitably study, not only in their fields, but by their study fire; and as an able American author, whom I have before quoted, remarks, in one portion of his excellent works "to him who studies the physical relations of the earth, sea and air, the atmosphere is indeed something more than a shoreless ocean, at the bottom of which he creeps along. It is an envelope, or covering, for the dispersion of light and heat over the surface of the earth: it is a sewer into which every breath we exhale, we cast vast quantities of dead animal matter: it is a laboratory for purification, in which that matter is recomposed, and wrought again into wholesome and healthful shapes; it is a machine for drawing up all the rivers from the sea, and conveying the waters from their fountains in the ocean to their sources in the mountains: it is an inexhaustible magazine, marvellously adapted for many benign and beneficent purposes. Upon the proper working of this machine depends the well-being of every plant and animal that inhabits the earth. Its movements, therefore, cannot be left to chance. They are guided by the laws that make all parts, functions, and movements of the machinery as obedient to order, and as harmonious as the planets in their orbits.—*Farmers' Magazine.*

### In Breeding Horses, do the Stock Take Most After the Sire or Dam?

So important is it that agriculturists should have definite ideas on this interesting subject, that we this week place at the head of our column, a query addressed to us by a correspondent from Kiaross. Judging from prevailing practice, we can scarcely avoid the conclusion, that farmers generally deny that the mare has much or any influence on the development and growth of the progeny. How else can we explain the notorious fact that an immense proportion of the breeding mares throughout the country are selected not on account of their superior appearance and qualities, but because age, accident, or hereditary effects have rendered them less valuable for work. How opposite is this to the more rational practice of those keen horsemen the Arabs, Money fails to purchase their best mares

According to the view first distinctly set forth several years ago by Mr. Orton of Sunderland, and concurred in by most good judges, the progeny appears especially to resemble the dam in the head, carcass, internal organs, and temper, whilst the influence of the sire is more especially noticeable in the colour, and the form and style of the limbs. The powers of endurance depending upon the deep chest, arched ribs, and well developed lungs, are the valuable qualities of many a priceless mare, and descend with great certainty to her offspring by various horses. On the other hand, the colts got by particular stallions usually exhibit great similarity in color, in the style of their action, and also in the defects of their limbs. If the horse has been subject to splints, spavins, or such other bony deposits, a large proportion of the colts will exhibit a similar tendency. This view, must not, however, be carried too far. It must not thence be presumed that the sire exercises no influence upon the development of the internal organs or temper, or that a mare's weak or mis-shapen limbs will not reappear in her progeny. It only justifies us in saying, that whilst the male and female appear to impress their characters tolerably equally upon the offspring, the characters, peculiarities, and even the diseases of the internal organs, are in the majority of cases those of the female parent, whilst the skin and organs of locomotion usually indicate the preponderating influence of the sire. From this law, however, two important practical deductions may be safely drawn—1st, never to breed from mares with narrow contracted chests, or weak loins, or delicate constitution: and 2d, to eschew as decidedly entire horses with weak, badly shaped, or diseased limbs.

But other influences are also at work affecting the share which the two parents have on the offspring. The parent in the highest state of health and vigor always imparts more than its own share of character. Thus the progeny will more resemble the active vigorous young stallion than the old worn-out mare to which they may be put. Hence the importance of maintaining in a healthy and natural state all animals intended for breeding purposes. It is further most interesting, that of the two parents, the best bred or highest descended is most strikingly reproduced in the offspring; and this is so notorious, and applies so constantly to all the higher animals, that breeders should avoid all half-bred sires, and use only such as have, in addition to good shapes, a fair unblemished pedigree. The character and qualities of such parents being transmitted through many generations, and more permanently and indelibly fixed, and are greatly more likely to be impressed upon the progeny. Thus a well-bred Short-Horn bull will produce from a lot of ordinary cows, calves resembling their sire and each other in color, heavy flesh, superior quality, and all other good points. The strong capability of such well-bred animals to

reproduce their good qualities may be judged off by the frequency and persistence in their stock of certain slight markings. How frequently, for example, do well bred bulls, with a strong infusion of Duchess blood, get their calves out of cows of all sorts and colors distinctively marked with the white spot on the loin, and frequently also on the tail!

To obtain a tolerably certain result in breeding, parents must be selected possessing tolerably similar characters. Uncertainty and disappointment are sure to follow from the attempt to breed from unlike or very dissimilar parents. Thus failure generally follows the union of the draught mare and thorough-bred horse, or *vice versa*. The dissimilar characters of such unlike animals cannot be properly blended in the offspring, and nondescript horses with big heads, deficient action, weak limbs, and bad feet, are the usual results. All this, we thought, was already sufficiently well known to every farmer and breeder, and yet we this week met an intelligent gentleman returned home from the Cape, and purchasing to take out with him a number of cart fillies to be put to an Arab, and from this violent and unsuitable union a good stamp of riding horse is expected. Time and money would be great better spent on strong, active, half-bred mares, which should, in our opinion, be put, not to an Arab, but a strong stout, well-actioned, short-legged English thorough-bred.—*North British Agriculturist*.

### Judging Stock, &c., at the Provincial Exhibition.

EDITOR OF THE AGRICULTURIST—SIR,—I take the liberty of sending a line to you, as I see some complaints in last number of the *Agriculturist* in reference to having too many Judges on Sheep. You say you want communications on subjects touching the different merits of the arrangements of the show. Formerly one set of Judges had to act on two or three classes of sheep, and I have frequently seen sheep shown in two different classes. When thrown out of the Leicester class, they would turn right into the Longwool.

I think by having sets of judges for every class, making them all come out at the same time, is the best preventive against such doings. The principle is a good one, and should be carried out every year, however much it may displease a few exhibitors. Surely if a man has got ambition to raise five or six distinct breeds of stock, he can or will try to employ men to look after his own interest when it would be only for one or two days.

I have been an exhibitor of late and shall be one this year, and think it behoves every one to try and have the show conducted in a

proper manner. I am sure the managers will not encourage anything else, as it is to the verdict of those shows that we look for satisfaction. Yours respectfully,

AN EXHIBITER.

Halton, Sept. 1862.

### Great Annual Sale of Shropshire Sheep.

As the Shropshire breed of sheep is gaining great popularity in Britain, and as some importations have, of late, been made by a few of our enterprising Canadian Farmers, the following account of the public sale, abridged from a late number of the *Shrewsbury Chronicle*, may prove interesting to many of our readers:—

On Monday week an extraordinary exhibition of stock was exposed for sale by Mr. W. G. Preece, at The Flask, in this town. The stock consisted of 250 magnificent rams of all ages; of these no less than 229 were absolutely sold or let; and on Tuesday 750 breeding ewes of the best blood in the county. The sale commenced with Messrs. Crane's lot, which were knocked down at sums varying from 9 to 46 guineas. These were followed by two belonging to Mr. W. G. Pearce; Robin Rough sold for 33 guineas, and Channock Ranger for 21 guineas. The Rev. C. P. Peter's rams ranged from 9 to 21 guineas; Mr. H. Smith's, of Sutton Maddock, 7 to 29 guineas; Mr. J. Evan's, of Uffington, 6 to 21 guineas; Mr. Stainer's, Wroxeter, an average of 12 guineas; Mr. Maddox's, Harley, averaged 14 guineas; and Mr. Claridge's, Pitchford, averaged 15 guineas. Mr. Joseph Meure's lot were let and sold at prices ranging from 6 to 13 gs; Lord Wenlock's sold at 7 to 21 guineas. and Mr. Sheldon's Brailleshouse, 7 to 27 gs. Mr. Horton's five sheep were let at the following prices:—One to Mr. Hatton at 70 gs.; one to Mr. Davies, Meer Old Hall, 60 gs.; one to Mr. Williams, 28 guineas; one to Mr. Henry Nicholls, 19 guineas; and the last to Mr. G. Cnreton, at 20 guineas. Mr. P. W. Bowen's lot sold on an average at 18 guineas. Mr. Mansell's, 16 guineas; Mr. Matthew's, 17 guineas; Mr. R. Lee's, 10 guineas; Mr. Lander's, 9 guineas; Mr. Thornton's, 8 guineas; and Mr. Stubbs, Weston, 20 guineas. Among Mr. Adney's was the grand five-year-old ram, Lord Harley, sire of Havelock, the winner of the first prize at Battersea. This fine old sheep was purchased by Mr. Horley of the Fosse, the owner of Havelock, for 39 guineas. On Tuesday, the sale of the ewes took place, and the competition was carried on with great spirit throughout. Messrs. Crane's ewes ranged from 3 to 5 guineas each; Mr. Evan's, Uffington, 2½ to 4 guineas; Lord

Wenlock's, 2½ to 5 guineas; Mr. Minor's, £3; Mr. P. W. Bowen's, 3 guineas; Mr. T. Mansell's, 60s. to 75s.; Mr. A. Mansell's, 2½ guineas; Mr. W. G. Preece's, 70s.; Mr. Thornton's, 60s.; Mr. Brooke's, Rowton, 55s.; Mr. Belliss's, Burlington, 2½ to 3 guineas; Mr. R. Lee's, 50s.; Mr. Pembrey's, 60s.; Mr. Plimley's, 60s.; Mr. Archerley's, Moortown, 63s.; Mr. Pitt's, Posenhall, 50s.; Mr. Preece's, Cressage, 63s.; Lord Berwick's and the Hon. N. Hill's from 2 guineas upwards; Messrs. Homer's, Sankey's, Harris's, &c., &c., from 40s. to 50s. each.

### Malignant Disease among Sheep in England.

In a recent number of the *London Times*, we find the following startling article, from which it would appear that *small-pox* has suddenly broken out among a large flock in the South of England, in a very malignant form. The facts are exceedingly interesting:—

It is impossible for words to describe fully the excitement which has for the last few days prevailed in Wiltshire and the upper parts of Hampshire, in the agricultural classes, in consequence of the breaking out of a malignant disease in one of the largest breeding flocks in the west of England—in a flock, too, that has for the last 50 years been regarded as one of the most healthy flocks upon the Beckinham Downs. For a few days there was some secrecy in the matter; but so completely impregnated is the whole flock that for the sake of flock masters generally it is desirable that a notice of the attack, and the means which are being taken to subdue it, should be forthwith promulgated. The facts are briefly these:—It is now about a month ago that Mr. Joseph Parry, of Allington, was riding alongside one of his folds, containing about 300 two-year-old ewes, when he observed one of the ewes lying by the hurdles. The animal looked in a pitiable condition, soon breathed its last, and was put out of the way, and for the time nothing more was thought of the occurrence. But, in a day or two after, other sheep in the same flock showed symptoms of illness, exhibiting great internal suffering, loss of appetite, heaviness and indisposition to move, and general prostration. The two-year-old ewes had, up to this time, been kept with their lambs; but thinking it better to separate them, the latter were now removed and put with other lambs upon the farm, the former being turned among the general breeding flock, making altogether 1,000 ewes and 700 lambs. The nature of the attack upon the two-year-old ewes surpassed all comprehension. That it was eminently contagious was certain. In the course of a fortnight, the same symptoms began to show themselves among the older ewes and among the lambs, and for days in succession as many as 20 or 30 of the

ewes died in a most loathsome state of disease, their bodies covered with pustules and a vicious matter running from the nose and from the eyes, rendering the sheep completely blind, and emitting the most foul stench that can be conceived. All local remedies are entirely unavailing. The malady was a mystery, and it became necessary that the best possible advice should be had, and that, too, without delay. Mr. Joseph Parry went to London, last Monday week, to consult Prof. Simonds, the well known lecturer at the Royal Veterinary College. After hearing Mr. Parry's explanation of the symptoms. Professor Simonds came immediately to the conclusion that the disease from which the sheep were suffering was small-pox; but as small pox has never been known to make its appearance except through infection—as, wherever it has appeared, its origin and propagation have always been traceable—its introduction into Mr. Parry's flock was perfectly unaccountable. Every suggestion which the Professor could offer was at once met by Mr. Parry. There had been no change on the female side of the flock for at least half a century. New male blood was only introduced once in two years; and it was now two years since Mr. Parry had purchased or hired rams from another flock. Neither could it have been imported by the shearers, as all the flocks which the same shearers had shorn this year, both before and after Mr. Parry's, were known, and in neither was there the slightest symptoms of disease. In short, there was no traceable means of accounting for the visitation. A "chill" could not possibly produce it, as a common cause of illness would not produce a special disease of this description. Its spontaneous appearance, therefore, is a thing unheard of. Moreover, it is a disease unknown among English flocks; the only occasion of its appearance here having been 1847, when some Merino sheep that had just been imported were sold with the small-pox upon them at Smithfield market. This was the first known appearance of the disease among sheep in England; and although it was then unfortunately communicated to two flocks belonging to Mr. Statham, a farmer at Datchett, near Windsor, and Mr. Weale, of Pinger, and for a time found its way into Norfolk and Hampshire, it was ultimately eradicated, and from that time to the present there has been no known instance of small-pox in this country. To account for it in the present case, therefore, seemed impossible, inasmuch as Mr. Parry's had always been a notoriously healthy flock—well tended, carefully fed, and with all the advantages of fine down air. Still, from the symptom, Professor Simonds had no doubt about the fact, and his visit to Allington on Friday last fully confirmed his previous persuasion. On examining the sheep he found them suffering in almost every stage of the disease, some in which the pox had first shown itself exhibited a staggering gait, with slight fever, and swelled eyelids; in others, when it had become more fully de-

veloped, red spots (easily discernable upon the bare parts on the inner surface of the legs) were found thickly studded over the body, while in those where the complaint had still further advanced, pustules (in form like the heads of linary small-pox) and malignant ulcers, emitting a thin stinking matter, were the distinguished features of the malady. A more loathsome sight than the sheep exhibit in this advanced stage can hardly be imagined. The contagious nature of the disease is truly astonishing. An instance is related (when it was introduced into England by the Spaniards in 1847) of its having broken out in a flock penned some distance off, but in the same field, while feeding on rape, clearly showing that infection was carried in the air from one flock to the other. Considerable danger has in the same way arisen on the continent (where the disease is well known) from the driving of a healthy flock on the same road or on the same down which had previously been travelled over by diseased sheep, or by the immediate transit of a sheep dog or a shepherd from one fold to another. But while it is so highly infectious to sheep, it is by no means so to other animals or to human beings. Cases are recorded in which children of all ages have been inoculated over and over again without any specific disease resulting; and the like experiment upon the cow, and even the goat, have been equally unavailing. Upon examining the flock on Saturday and Monday and again on Tuesday, Professor Simonds found that a great number of sheep had already passed through the most trying part of the malady while some (as many as 170) were declared by him to be perfectly convalescent. This being the case, it impossible to say how long the disease has actually impregnated the flock; but to reduce its continuance to a certainty, and as the most effectual means of preserving those that have not already been attacked, Prof. Simonds suggested that the whole of the sheep should at once be inoculated; and, having placed the case entirely in the hands of the Professor, Mr. Parry assented to this proposition, and the whole flock of 1,700 sheep and lambs (exclusive of those which have died and those which have recovered) are accordingly at this moment either in an incipient or a malignant state of small-pox.

Adding misfortune to misfortune, the old shepherd who had tended the flock for the last thirty years dropped down dead among his sheep last Thursday evening. Proud of his flock, which had borne a high character, and reflected credit upon his management, the poor man seemed to feel the visitation most acutely; and there is no doubt that the anxiety under which he had been labouring for the previous month, acting upon a diseased heart, tended to bring about his melancholy end. He was endeavouring to catch one of the sheep on Thursday evening, when he fell with the animal under him, and almost instantly expired.

## Horticultural.

### Toronto Horticultural Society.

#### THE HORTICULTURAL EXHIBITION.

The last exhibition for this year of the Horticultural Society in their Gardens, Gerrard street. The weather was fine, though, before the sun went down, exceedingly warm. The attendance, considering the attractions, and the large number who have visited previous shows, was small. In the evening, when the temperature was pleasant, and the lamps were lit, the largest numbers were there, and to judge by the merry peals of laughter which ever and anon rang through the darkness, the folks enjoyed themselves amazingly. The exhibition was not a large one, but in quality, the fruits, flowers, plants and vegetables shown have never been excelled in Toronto, at this season of the year. Perhaps the grapes attracted as much attention as anything else. The people hung around them with their eyes, as they were not permitted to do so with their teeth. The most luscious and beautiful specimens came from the vineries of Mr. Eccles and Mr. Gzowski. The exhibition of cut flowers was very fine; the colours good, and the specimen placed on view numerous. The collection of bouquets was perhaps the best, though certainly not the largest, offered at any exhibition of the Society. There has been considerable improvement during the last three years in the making of bouquets. Our florists are beginning to understand that there is something more necessary to this than the mere tying up of a bunch of flowers. They must be carefully assorted, the colours contrasted or blended one with the other, "violent" hues must be subordinated, and the best flowers made prominent, without at the same time placing the rest out of sight. These requirements have to a great extent been met, but there is room for improvement. One of the most tastily "set up" bouquets was exhibited by Mr. George Tattle. It consisted merely of wild flowers gathered from Canadian woods and fields, but looked very beautiful. Fall flowers, such as astorias, phloxes, verbenas, asters, dahlias, &c., were plentiful, and well grown—the phloxes especially being very fine. Stove and green house plants amongst which were some new varieties, were exhibited by Hon. I. C. Morrison and Hon. S. B. Harrison. Apples, pears and plums, celery, cauliflowers, parsnips and onions occupied considerable space, and formed a good representation of Canadian vegetables. The judges found their duties very onerous, and had more than ordinary difficulty in deciding between the merits of many rival claimants at their hands. Having discharged their duties, however, they with the Committee adjourned to lunch. When justice

had been done to the eatables, the chairman, Hon. G. W. Allen, in proposing the health of the judges, remarked that in order to avoid jealousy among exhibitors, the judges were now brought from a distance, so that no charge of favouritism or of partiality could be preferred against them. Mr. Miller of Guelph, responded. The healths of the active and attentive secretary of the Society, Mr. J. C. Small; and of its liberal President, Mr. Allen, was also drank. Mr. Humphries kindly entertained the company with a few good songs, interspersed between the speeches. We nearly forgot to mention that the band of the 30th was in the Gardens all day. During the evening they played a variety of popular pieces, which were greatly enjoyed by the company.—*Globe*.

### Dwarf Apple Trees, once more.

EDITOR OF THE AGRICULTURIST,—Friend Werden's last article in the *Agriculturist* about Dwarf Apple Trees, would seem to demand a reply more lengthy and pointed than I have at present either time or inclination to devote to it. With your permission, however, I will again venture to make a few remarks, not in defence of those Nurserymen in Rochester or Toronto, who have "humbugged" Mr. Werden, but in defence of those charming objects of the fruit garden, viz. Apple Trees upon the Paradise stock.

To state in the outset that such trees are more hardy, will generally bear much earlier, and grow much slower than when grafted upon the common apple stock, would be only to repeat what every Horticultural and Agricultural Journal, both in Europe and America, have stated again and again. If Mr. Werden denies this, why, we must agree to differ. After all his cry of humbug, however, he says:

"Now I do not say that there is not such a thing as a Dwarf Apple Tree as described, but, unfortunately for me, I have not got them." Surely Mr. Editor, the trees are not to blame, and Dwarf Apple Trees are such, whether Mr. Werden has them or not; and his crying humbug, cannot alter the character of the trees in the least. If any nurserymen have cheated Mr. Werden, let the persons be named and blamed, but let not genuine Dwarf Apple Trees be called a humbug. Mr. Werden says, "I hope Mr. Arnold will take pity on us and send me 25 genuine Dwarf Apple Trees." No, friend Werden, Mr. Arnold will do no such thing, he has too much feeling for his Dwarf Apple Trees to submit them to your, "continual warfare of pruning, cutting back, pinching and nipping." The fact is, Sir, that apple trees dwarfed, nineteen varieties out of twenty, require scarcely any nipping, pinching or pruning; but like the rebels in the South, all they ask is to be let alone. Why Mr. Editor, if I should send Mr. Werden

25 trees would he not again cry out humbug, and say that I had written all this for the purpose of selling my trees; most assuredly he would, and on my refusing to send the trees, perhaps Mr. Werden will say that I am afraid to put the trees to the test; but in order to test the thing fairly, let Mr. Werden put 25 Dwarf Pears of his own selection, and I will put 25 Dwarf Apples of my selection in the hands of the Directors of the the Toronto Horticultural grounds, or if he prefer it, in the hands of Judge Logie, the President of the U.C. Fruit Growers' Association. And if my Dwarf Apples do not yield more fruit for the first two, or if he prefers it twenty years; than Mr. Werden's Dwarf Pears, then I will pay for the Pears. And if the apples do yield more than the pears, then shall Mr. Werden foot the bill. But Sir, to come to the point, and test the question fairly as to whether the apple will grow slow and bear earlier upon the Pardice stock than upon the common apple stock: Let us walk out amongst them. Now, Sir, here we are, and here stands a Dwarf (Red Astrachan) planted in 1853, it measures six feet in diameter, and stands six feet high, it has borne 7 full crops in 9 years, and every Spring it is one mass of blossoms, and the sight of the blossoms alone well repays me for the ground that it occupies, and for the trouble of cultivating it. And here stands (a few rods from the Dwarf) a Standard of the same variety, planted at the same time, and both have received the same cultivation, viz., ordinary cultivation, or such as other trees or bushes generally get in the gardens of our thrifty farmers or mechanics. This tree is at least three times as large as the other, every way, and has borne me just three apples in nine years.

I could give at least a dozen other instances with the same results as to growth; but, as Mr. Werden, says he "would not mind going a hundred miles to see a bush of the Northern Spy or St. Lawrence in full bearing at the size of two feet." I will instance the St. Lawrence and let that suffice. And here in the nursery, rows of 3 year old plants, in the first 8 trees, there are four bearing fruit, thus: five, four, three, and one severally; and not one of these bearing trees is more than 2½ feet high. But my two standard specimens, St. Lawrence, 9 years planted, and at least 14 years old, fine, large, healthy trees, have never yet yielded me a dozen apples. And now, Mr. Editor, one word more and I have done. As Mr. Werden has referred us to his prize essay on fruit culture, let us turn to it on page 154 of the Transactions of the Board of Agriculture for the year 1859, and let Mr. Werden's "fellow farmers" read it—here it is, "As for dwarf apple trees, I feel so well satisfied that they will give good satisfaction, that I recommend every man that has ground only for a garden, to fill it up with these trees, \* \* \* \* and, my word for it, it will be

more profitable than 50 acres to agricultural purposes." What, a garden of dwarf apple trees more profitable than 50 acres to agricultural purposes! Tell it not in Gath, publish it not in your city, Mr. Editor, lest some of those wicked politicians should get hold of it, and should attempt to prove from this prize essay that our noble, Provincial Agricultural Association was a humbug; that the funds of the society were squandered upon essays on fruit culture, which were calculated to lead the people astray; if the advice respecting dwarf apple trees was followed. Surely, sir, if the term humbug will apply to any one in Canada who has written on the subject of dwarf apple trees, he who wrote the prize essay on fruit culture for 1858 is the man. That they afford a great amount of pleasure, and some profit, but few that have tried them will in my opinion deny. But the real profit in dollars and cents is another matter, and I would very much like to see the portrait of the man who had become rich from the profits arising from the sale of fruit that was grown either upon dwarf apple or dwarf pear trees.

Yours, &c.,

CHARLES ARNOLD.

PARIS, Sept. 13, 1862.

### Interesting to Fruit Growers.

Any person travelling through the country will observe a general decay of fruit trees. Old orchards in particular, are in many locations an entire failure. What is to be done? Are we to be deprived of fruit, or is there some way to recuperate and prevent further decay? So far as the winters have an influence, we probably need not hope for any change, unless their severity be abated. Extreme warm weather, followed immediately by extreme cold has been the cause, I think, of the general decline of fruit trees. Then the borers and mice have made strange havoc among young trees. I set a row of trees, some third of a mile, near the wall, some five years since. Now there are a very few remaining, and several of those were saved by inserting scions across the wounds inflicted by mice—thereby carrying the sap from top to root. I have recently examined an invention called a "Tree Protector," by Homer B. Record of Turner, consisting of a shield and bonnet. The shield prevents the mice, borers and other insects from access to the trunk of the tree, while the bonnet prevents them from ascending into the branches. The material used is wire cloth, light canvass or what may be equivalent. The cloth is cut so as to go about one third around the tree and to extend upward about one foot. It is slightly enlarged at the bottom so as to conform

to the tree. The top of the shield is provided with an elastic band, somewhat larger than the part of the shield to which it is attached and expands with the growth of the tree. The bonnet is composed of the same material, in the form of a cane and goes around the tree above the shield, with which it may be connected by a small wire, or it may be detached. This too is supplied with an elastic band, so as to expand with the growth of the tree. The bands pass around the tree and fasten with a hook or button. The underside of the bonnet is smeared with tar, then a quantity of cotton or its equivalent applied, which adheres closely to the bonnet. Thus it will be seen that all insects that attempt to ascend the trunk of the tree will become entangled in the bonnet and there die together with their larvæ. The expense for small trees will be from ten to fifteen cents, I think.

Fruit growers should examine this apparatus and satisfy themselves of its utility. I see no reason why it should not produce desired result.  
—*Maine Farmer*.

T. C.

### Decayed Orchards.

It is a well known fact that fruit trees of various descriptions in most parts of Canada have suffered severely from the inclemency of the weather. Many orchards—some of them not old—are in consequence in a state of rapid decay. Indeed from the depredations of insects and other causes, fruit-growing in this Province seemed fast approaching an end. New trees, however, have of late produced occasionally heavy crops, and the produce of most kinds of fruit the present season is abundant. We take the following from a recent number of the *Maine Farmer*; it has reference to the Sandy River valley in that State:—

The orchards throughout the valley seemed to have suffered greatly by the severity of the winter, the trees in most instances presenting the appearance of having been scorched by fire. It is a fact clearly demonstrated by observation—although it is not easily accounted for—that apple trees situated upon elevated localities are found to be more thrifty, and withstand our winters better than those in valleys and low places. With the sad sight which orchards here present—if taken as an average of the condition of those throughout the State—it will not be long ere we shall cease to be an apple producing region, unless something is done. The proper remedy is to be found in commencing anew, and starting young orchards again. We were therefore gratified to see numerous young orchards, some just coming into bearing; and also a num-

ber of nurseries of apple and other fruit trees. It should be borne in mind that orchards need a rotation as much as other crops, and it will be far better to begin a new orchard on a new piece of ground, than to patch up and doctor the old one.

### Fruit Prospects and Birds.

In our last issue we drew the attention of fruit growers to the fact that an extensive show of blossoms is no certain criterion of a plentiful crop of fruit, but very generally the reverse.

Birds are too indiscriminately accused of destroying the fruit buds. They do no such thing. The fact is, when they are supposed to be so engaged, they are actively employed dislodging and devouring insects which have already taken possession of the buds, being there hatched from the eggs deposited by the adult females; and if left unmolested by these useful creatures would not only devour the buds, but continue the multiplication of their species until in time they would eat up every green thing. The infinite wisdom of the Great Creator is in all things seen to be perfect; and in none of his works is this more beautifully displayed than in the ordering of that balance which exists between the animal and vegetable kingdoms, and which if left alone, would work harmoniously for the benefit of man.

The great majority of butterflies, moths, and beetles, in their caterpillar or grub state, feed on vegetables, and it is only when in that state they become our enemies; and their power of propagation is so great as to have no parallel in the whole range of animated nature. Many of them are so minute as to be almost invisible to the naked eye, yet the mischief they occasion is beyond all human calculation, and their habits are so curious and obscure as to be only understood by the scientific entomologist. The cultivator of the land, whose interest is so much at stake in respect to the economy of these, the almost lowest grade in animal life, treats the study of entomology as a chimera and delusion; and so long as he shuts his eyes to the truths of science, so long will he suffer in his basket and in his store.

Certain classes of insects are made to feed upon vegetable food alone; so also have certain classes of birds to be maintained. Hence birds are classed as insectivorous, granivorous, and carnivorous. To understand their classification so as to be able to understand one of these classes from the other, should be the study of both the gardener and the farmer, if they wish for the preservation of their crops; but instead of inquiring into these distinctions, which should be considered as first principles for their guidance, they have through ignorance, maintained a cruel, unnecessary, and mistaken war of extermination alike against their feathered friends and foes.

It is at this season of the year that the great utility of birds may be most easily determined; and on this point a very slight degree of observation must lead conviction to the mind of any rational being. Insects are making sad havoc in our orchards and gardens at the present moment, and to them, in addition to the effects of superabundant blossoms, noticed in our last, is to be attributed the damage doing at this time, for we have not to complain of late spring frosts this season. Our contemporaries are one and all giving very dismal accounts of the fruit prospects in every part of the kingdom. The *Times* deemed it necessary to join in the universal cry in favour of the birds, and even *Punch* has come out in his own peculiar manner with a well timed and forcible broadside.

Birds when encouraged not only keep in check our insect enemies, but they greatly reduce the number of our noxious field and garden weeds by feeding upon the seeds after the insect season has passed.

The following birds are insectivoreous—that is, feeding insects alone, and abstaining from fruits and seeds:—The golden-crested wren (*Regulus iscertatus*), wood[wren (*Sylvia sibilatrix*), the willow wren or hay bird (*S. fitis*), the chiff-chaff (*S. loquax*), the nightingale (*S. Luscinia*), the whin-chat (*Saxicola rubetra*), the stone-chat (*S. rubicola*), the wheat-ear (*S. Cenanthe*), the yellow wag-tail (*Motacillaflava*), the tree-pipet or titlark (*anthus arboreus*), the meadow-pipet (*A. pratensis*), the cuckoo, fly-catcher, the flusker or lesser butcher-bird, the night jar, the sedge-bird, the wryneck, the creeper, the bottle-tit, and to these several others might be added.

The following are insect-eaters, but also eat fruit and seeds:—Hedge sparrow, common wren, red-breast, red-stark, tom-tit, cole-tit, marsh-tit, greater-tit. The number of seeds of weeds that these devour are immense.

The following are fruit-eaters, and also feed on insects:—Black cap, garden warbler, white throat, babillard, missel-thrush, song-thrush, blackbird, and starling.

The following are grain-eaters, some of which, like the house-sparrow, eat insects largely:—Gold-finch yellow-hammer, reed-bunting, corn-bunting, skylark, woodlark, linnet, chaffinch, bull-finch, mountain-finch, house-sparrow, and tree-sparrow.—*Scottish Farmer*.

### The Birch—Its Varieties and Uses.

A correspondent of the *Cultivator* thus writes of the birch: "There are seven species described by the botanists of New England.

"The White birch, sometimes called the gray birch, is a well known tree, and cannot be mistaken for any other tree of the celebrated birch family. It is about a third tree in rank, growing from 20 to 30 feet in height, and sometimes even higher. It has been denominated the com-

panion of the pitch pine, which together usually indicates a light soil. Coleridge calls it the "lady of the woods." It grows rapidly in all soils. It makes good stove wood. One man said of it, "white birch is the most valuable fuel I have, for I can make a good fire of it, and have all the wood left." In good land a crop of birch wood may be taken off once in ten years. It ripens seed in September and October. The bark was formerly used by fishermen along our brooks for a torch-light. The seed should be sown in the fall if it all, and covered lightly.

The paper or Canoe birch is indigenous to deep soils as well as American, and is natural to river banks and intervals. It is a beautiful and most attractive tree. The smooth white bark of the trunk may be separated into delicate horizontal layers, which may be written on by pencil or pen and ink. It grows 40 to 70 feet in height, and varies from one foot to three feet in diameter. The bark was used in olden times in New England, as by the Indians, for making canoes. Michaux enumerates a great many uses to which it has been put in Canada and Maine. The wood takes a fine polish, and is therefore used for hat blocks and cabinet work, and for making shoe-pegs. The bark was formerly used beneath shingles, as I have seen in stripping roofs many years ago. It is almost imperishable.

The Black, Sweet, or Cherry birch is easily distinguished from either of the preceding species, from the dark color of its bark, which gives it the most common name of Black birch. The resemblance of its bark and leaves to the cherry has led some to call it the Cherry birch, and the pleasant sweet taste of the inner bark has led others to call it the Sweet birch. It grows from 30 to 70 feet high, and is from one foot to two feet, and more, in diameter. It is common in deep soils, and flourishes best in mountainous regions. The wood is easily wrought, and is used in arts. It is a delicate rose color, which deepens from exposure. It is used by some for ox-yokes. It makes good fuel; and its bark is used in coloring woollen drab, resembling or bordering on a wine color.

Yellow birch is a lofty tree, growing from 40 to 80 feet in height. It is common in moist woods and swamps. The wood is used for various purposes, especially in chair work, such as posts and bars. It is a valuable fuel.

The Red birch, in aspect, differs from the others. It is found bending over streams, with its roots in the water. It grows with the red maple and the swamp oak. The bark lacks the tenacity of the White and the Canoe birch. On old trees the bark is a dark grey, and very rough. Within, it is of ocre-red. The wood is white and hard. For fuel it is nearly equal to hickory. It is of rapid growth. Yokes are made of it; they are likely to crack unless seasoned in log under cover or in water. It is easily propagated

along streams, and serves as a protector of banks liable to wash from the water coursing therein, thus adding beauty to the stream, while growing valuable timber and wood.

The Dwarf or Tiny birch is from one to three feet in height, and is common among the Alpine heights of Maine and New Hampshire. It is not common away from mountainous regions in New England.

The Low birch, or as some call it the Dwarf birch; the latter being called by such, the Tiny birch—grows in mountainous districts, to the height of from two to six feet.

Here I have attempted to sketch the natural history of the Birch Family, with which I, with most New-England-born boys, have been very familiarly acquainted, even from earliest recollections.<sup>71</sup>

### Qualities of Fine Vegetables.

The garden is the most important appendage to many of the substantial comforts, and some of the most refined luxuries of human sustenance. Its cultivation furnishes a source of health, pleasure and economy, which may be enjoyed by every industrious owner of a few rods of ground, who can devote a little time between his hours of business or labor to this delightful employment. If his occupation and extent of his enclosure will allow him to indulge his taste for fruits and flowers, he might take much pleasure and derive great profit from the management of the vegetable garden alone.

For the purpose of selecting an assortment of the purest vegetables, best suited to the use for which they are grown, we have fixed upon certain qualities which we seek amongst the different kinds.

In the blood beet we always look for a deep color, smooth, handsome form, small top and sweet, tender flesh. In the orange carrot, small top, smooth root, and deep orange colour. In the cabbage short stump, large, compact head, with but few leaves. In the cucumber, straight, handsome form, and dark green color. In the lettuce, large close head, pleasant flavor, with the quality of standing the heat, without soon running to seed. In sweet corn, long ears, very shrivelled grains over the end of the cob. In the cantelope melon, rough skin, thick, firm flesh, and high flavor. In the water melon, thin rind, abundant and well-flavored juice, and bright red core. In the onion, thick round shape, small neck, deep color, mild flavor, and good keeping quality. In the parsnip, small top, long, smooth root, rich flavor. In the pea, low growth, full pods, large and tender peas, rich flavor. In the scarlet radish, deep color, small top, clear root, and quick, free growth. In the squash, medium size, dry, fine-grained, deep-colored flesh. In turnips, handsome form, small tops and tap root, sweet crisp flesh.

Those who have never seen better sorts than they possess, suppose they are of the first quality, when they may be very inferior, or almost worthless, when compared with the finest varieties.

### Domestic.

**A SIDE DISH.**—Boil some eggs hard, cut them in two, the yolks to be taken out and beat up with a little parsley, pepper, and salt. Replace this into the whites, and serve up with a nice white sauce,

**PANCAKE PUDDING.**—Make a few thin, small pancakes, fry them a light brown, spread them with currant and apricot jam alternately, and roll them. Put them all round a mould; make some rather thick custard and pour into the middle, strewing it with the bits of pancake you have cut off in fitting them round the mould. Cover the whole with a small, thin pancake, and steam it for two hours.

**FRENCH SOUP.**—Take a large lump of butter, a table-spoonful of flour, and brown them in the saucepan you mean to cook the soup in. Cut up carrots, onions, celery, sorrel, and potatoes together very fine, then put all in the saucepan, with pepper and salt. Pour boiling water over them, and let all stew over the fire from three to four hours—it cannot simmer too much. A little thyme, parsley, cress and mint is a great improvement.

**TETE MARDREE.**—Take half a pig's head (if fresh, so much the better), the ears, and two or three feet, boil all these, in as little water as possible, till you can slip out the bones. Take all out, and, having separated the bones, boil them in the liquor until it is reduced. Cut the meat when cold, into squares, put it into the liquor, season to taste, and when boiling pour the whole into a mould. Leave it several hours to cool and set, and when turned out it will form a very pretty dish for luncheon or supper. The stronger the liquor the better.

**TO MAKE PORK SAUSAGES.**—Three-fourths of what are passed off for sausages in London, are nought but a *farrago* of faded meat of different kinds, chopped up with sour bread and faded lard; inasmuch, that if the parties who ventured to eat them knew in reality what "London sausages" were composed of, they would sicken at the thoughts of them. To regulate your appetite with a degree of wholesomeness and cleanliness, let your sausages be made after the following manner:—Obtain two pounds of lean young pork from a respectable dairy, supplied by a country farm connection in the country; let the same be chopped up as finely as it may be required to be; add to the meat six green sage leaves,

half an ounce of ground mace, the peel of half a lemon cut up very fine, one shalot, ditto, and one quarter of a pound of pigs' "flare," ditto; add salt to your taste. Mix up the whole suitably together, have your skins ready damped, and introduce your sausage meat into the same, filling them up somewhat loosely. You can make them of any size you please by twisting the skin or bladder round where you wish to leave off, and continue to fill up in succession, according to the size you have selected. Prick before cooking them with a coarse needle; invariably broil them, and, when they are done, serve them up with a basin of good apple sauce. Have mustard and ground pepper at hand.—N. B. Some persons are in the practice of mixing chopped veal with their pork, which makes very little difference in the flavor of the meat—indeed, if roast veal was eaten with mustard, not one in ten would contradistinguish it from pork.

**WASHING SILKS.**—No person should ever wring or crush a piece of silk when it is wet, because the creases thus made will remain forever, if the silk is thick and hard. The way to wash silk is to spread it smoothly on a clean board, rub white soap upon it and brush it with a clean hard brush. The silk must be rubbed until all the grease is extracted, then the soap should be brushed off with clean cold water, applied to both sides. The cleansing of silk is a very nice operation. Most of the colors are liable to be extracted with washing in hot suds, especially blue and green colors. A little alum dissolved in the last water that is brushed on the silk, tends to prevent the colors from running. Alcohol and camphene mixed together is used for removing grease from silk.

**WASHING WOOLENS.**—If you do not wish to have white woolens shrink when washed, make a good suds of hard soap, and wash the flannels in it. Do not rub woolens like cotton cloth, but simply squeeze them between the hand, or slightly pound them with a clothes pounder. The suds used should be strong, and the woolens should be rinsed in warm water. By rubbing flannels on a board and rinsing them in cold water, they soon become very thick.

**OUR DAILY TABLE.**—If the art of "plain cooking" was better understood, the masses of the people—the bone and sinew of the land, who perform most of the hard labor—would have vastly better tables at less cost of living. But the art of plain cooking is *not* understood half so well as it ought to be, and the consequence is that we live worse at a greater cost than we otherwise would. But how can we expect anything else when our daughters, even in the country, are, to a great extent, so theoretically brought up? How

many mothers fail in this respect to practically instruct their daughters in all the duties of house-keeping—cooking and baking in all their branches, as well as in the most economical system of management in the household. Many who read this will, I have no doubt, feel some compunctions at this grave neglect of parental, I may say, religious duty. But when I refer to the young women in our towns and villages, tenfold is the solemn injunction of our Lord utterly ignored. Especially is this the case in villages where factories abound, wherein are employed a large proportion of the young women of the place. How much do *they* know of house-keeping when they come to get married? Absolutely and literally nothing. Residing with their parents, and receiving good wages, and with plenty of leisure, what do most of them do? They spend their money upon their backs, parade the streets, join parties in dancing and flirting with the young men whom they attempt to capture with their finery, and let house-keeping never enter their thoughts. They all look forward to be married and go to housekeeping—and pretty wives and house-keepers many of them make, and comfortable lives they lead their duped husbands. Pardon me for being thus severe. I feel obliged to be so to enforce attention to what I say. I want *all* our young women, wherever they may be, and whatever may be their condition or employment, to give heed to what I say, who was once young like themselves and not old like now. *I want them all to study the business of housekeeping.* I want them all to be good cooks, good bakers, and good managers—but this important knowledge can be acquired only by systematically going through and through the whole routine of house-keeping. They will find it to be the most valuable *accomplishments* they can possess—accomplishments which will be more admired by a sensible husband and more lasting and valuable, and better calculated to secure his affections and promote his happiness, as well as the general comfort of the family, than any others that were ever created or invented. I speak from what I know. MARTHA, *In Germantown Telegraph.*

## The Dairy.

### Cheese Dairying—its Permanency and Profit.

There is perhaps no branch of business more permanent or profitable than dairying; and this must necessarily be so, from the fact that but little land, comparatively, is suited to the business, and hence there can never be that wide competition as results from other species of far

ming. The characteristics of a good dairy region, are a beautiful supply of springs and streams, and of pure and never failing water, and soil that will hold the grasses permanently. When these are wanted it is evident that dairy farming cannot be conducted with success.

The demand for cheese is increasing, it is believed in a ratio beyond that of the business of manufacturing, and as quality improves, foreign markets will gladly take all the surplus (after supplying home consumption,) that this county can produce, and at such prices as to render the business permanent and profitable. We are assured that England cannot manufacture cheese at less than 12½ cents per pound,—her rents and taxation are extremely high, while the quantity of cheese produced per cow, does not exceed that of our best dairies. What the foreign markets demand, is choice quality, and if we can furnish such as shall be equal to their own manufacture, the English Dairyman must ultimately be driven from the field, and turn his attention into other channels of agriculture.

The statistics of exportation for the last three years give abundant evidence of the progress we are making in supplying Europe with dairy products. The Journal of Commerce, under date of January 4th, 1862, publishes the following table of exports from New York, from which it appears that the increase in exportation of butter and cheese for the past year over that of 1860, it is truly astonishing, and affords encouraging assurance that our efforts to produce a really desirable article, have been and will be responded to by our European neighbors in a satisfactory manner. The subjoined table is the one referred to:

*Exportation of Butter, Cheese, and Lard  
from New York for 3 years.*

|          | lbs. butter. | lbs. cheese. | lbs. lard. |
|----------|--------------|--------------|------------|
| 1859.... | 2,494,000    | 9,287,000    | 11,015,000 |
| 1860.... | 10,987,000   | 23,252,000   | 18,860,000 |
| 1861.... | 23,149,000   | 40,041,000   | 47,200,000 |

Cheese manufacture for several years past has undergone important changes, and the desire to produce choice qualities is becoming more and more general. This has been brought about partly by the system of buying and selling for cash on delivery, which has been gradually adopted in this county, and discrimination according to the quality of cheese; so that every load and dairy of cheese stands on its own merits. A few years more of steady persevering effort on the part of our dairymen, to improve in this direction, will render Herkimer County cheese as far famed and widely sought for as its excellence deserves; continuing as it ever has done, to hold that prominence in market, that the genuine Jonhansberg holds among wines.—*Country Gentleman.*

## Veterinary Department.

(Conducted by A. Smith, V. S.)

### Bowed Legs, or "Sprung Knees in Horses.

Bowed or sprung knees is a very great deformity as well as a serious eye-sore to the owner of the subject; at the same time it seriously impairs the usefulness of the saddle-horse, for he is apt at any time to fall, bruise his own knees and break his rider's neck.—As a draught-horse, however, such an animal may prove serviceable, and perform ordinary duty, and, should he fall, he hurts no one but himself; yet he should never be used as a shaft-horse in a one-wheeled vehicle, because he is there liable to stumble and fall in consequence of the weight being thrown near the shoulders and four-legs.

This deformity is sometimes congenital, and manifests itself very soon after birth, yet such cases are rare; it is usually the result of rheumatic affection, which attacks the flexor tendons, their sheath, and the metacarpal ligament, which confines them to the back part of the knee.

When the disease is not congenital, we may observe predisposition lurking in the parts, which is known by the flexor tendons (which bend the leg,) being tied close in at the upper part of the cannon or shaft bone, just beneath the knee; any one with a practiced eye can easily detect this condition, for there is a want of symmetry in the limb, and at the same time, as light deviation from the perpendicular line may be observed in one, or perhaps both, fore legs.

Should the slightest curvature appear, and gradually augment, without any assignable cause, it may be inferred that the animal, owing to some peculiarity of conformation in the fore legs, is predisposed to curvature, or bowed legs; in such cases, overwork and rapid travelling become the exciting causes. At other times, when predisposition exists, faulty shoeing may prove an exciting cause; for example, when by paring too much from the toes, the heels are left thick, or when the heels of the shoe are made thicker than at the toe, the foot is then made to assume a faulty position, the tread is not natural, and curvature may be the result. The remedy is to pare the heels, and make the shoe of an equal thickness all around.

When the deformity is known, or supposed, to result from inflammatory rheumatism, which may be known by its sudden appearance, or its migrating from muscles to tendons, attended with more or less lameness, the parts are to be rubbed twice, daily, with a portion of equal parts of olive oil and sulphuric ether,

at the same time the animal must be properly shod.

In cases when a *gradual* curvature has taken place, and the animal is very much deformed, nothing short of a surgical operation can be of any benefit, and even this cannot be relied on in the case of an aged animal. The operation consists in a division of the flexor tendons, and the application of a shoe, having a long toe-piece welded to it, which prevents the animal from bending its knees; in this way the tendons cannot unite directly, but they finally do so indirectly, by *granulations*, which are thrown out from the divided surfaces, so thus the tendons acquire an inch or so of length.—*American Stock Journal*.

**LAMBS DYING FROM WOOL IN THE STOMACH.**  
—Lambs very frequently swallow particles of wool, which, in playfulness, they suck and bite from their dams; to prevent which, the dams, when this occurs, should be smeared with a mixture of aloes and water, or assa-fœtida and water. When they swallow the wool and it gets mixed with curd in the stomach, it forms hard balls that are indigestible; but the administration of a teaspoonful of soda mixed in water twice or thrice a day dissolves and digests the curd, if not too far gone. Calves frequently die of the same disease, and the only remedy yet found is the soda.—*Irish Farmer's Gaz.*

### Miscellaneous.

#### The Manufacture of Leather Cloth.

The manufacture of leather cloth as a substitute for Morocco leather, was commenced in the year 1749, in the city of Newark, U. S. The first specimen of it seen in this country, was exhibited in 1851. The Americans have had the merit of producing many labor-saving machines and articles of domestic convenience, and many of them are becoming increasingly known and extensively adopted in this country. It is certain that this article of leather cloth has superseded the use of leather for many purposes to which the old material has hitherto been applied, besides being put to uses for which leather is wholly unsuitable. Messrs. Crockett, the inventors and patentees commenced the manufacture of leather cloth in England in 1855, and their factory was a large workhouse, situate in one of those dreary, unpicturesque marshes at West Ham, in Essex, a locality somewhat famous for its insalubrious manufactures. The firm was known as the "Crockett International Leather Cloth Company." In 1857 Messrs. Crockett surrendered their business to a company formed under the

title of "The Leather Cloth Company Limited," which purchased the entire European business.

The new company, with a paid up capital of £90,000, and having Mr. A. Lorsont as their managing director, began the enterprise with great energy. They erected substantial and extensive premises which cover ten acres of ground, employing upwards of 200 men. They produce daily 1000 pieces of 12 yards long and 1½ yards wide, or 15,000 square yards; sufficient if laid end to end to reach from their factory to the warehouse in Cannon Street West—a distance of seven miles.

It will be evident that an article intended to resemble leather should be pliant, supple, and not liable to peel off or crack. These excellencies are to be obtained by the peculiar ingredients of the composition with which the cloth is covered, and the method of applying it. On entering the factory our attention was first directed to the boiling room, in which there are 12 furnaces, with a large cauldron over each for boiling linseed oil. This process is attended with considerable danger from the liability of the boiling oil to generate gas and explode; hence, a man is stationed at each cauldron stirring gently the boiling mass and watching a thermometer inserted in it, and which at the time of our visit stood at 580°. The oil is supplied to the boiling house by pipes from an adjoining building, where there is a huge tank with nine compartments containing 3,200 gallons each, or 28,800 altogether, amounting to 122 tons of oil. The boiled oil being allowed to cool is conveyed on a tramway to the mixing house, where, in a puddling machine, it receives several other ingredients, the principal ones being lampblack and turpentine, which being mixed into a composition is ready for use.

The cloth to which this composition is applied is known by the name of "greys," or unbleached cotton. It is of a peculiar manufacture, and made expressly for the company. The store room is a spacious building, and will contain an immense stock; at present it has 25,000 pieces, or 300,000 yards. Here the cloth is calendered, and cut into lengths of twelve yards. The two ends of each length are sewn together to make it endless; two sewing machines are in constant operation at this work. The pieces are then removed to the "milling" rooms, so called because they contain the mills in which the cloth receives the composition. These mills are rough looking wooden structures, having a drum at one end and a roller at the other, over which the cloth is passed, and then tightened by a crank and wheel at one end. A large frame-knife or scraper, is then dropped down close to the cloth, a measured quantity of composition being laid on the cloth along the edge of the knife, the mill revolves, and the cloth receives as much of the composition as can pass under the edge of the knife. The piece is then

carried to the heating room adjoining, and hung up on the rack to dry till next morning.

There are on the premises six milling rooms, with three mills in each, and having three men attendant upon each mill. The adjoining rooms for drying are heated by three rows of pipes laid along the wall. These pipes, during the day are at a temperature of about 130°. The temperature is increased towards the evening, and during the night to 160°, and it is the duty of the watchman to open the doors for ventilation and cooling preparatory to the men resuming their work for the next coating.

Of course, in a building so greatly heated, and having so much inflammable material within it, the danger of fire is imminent, but every precaution has been taken which prudence could dictate. The building is fire proof, the floors are of metallic lava, and the roof which is flat, is of the same material. A large pipe runs up the outside wall by the partition which divides the drying rooms, into each of which runs a branch pipe with a valve, which can be worked from the outside. A deluge of steam can by these means be poured into the rooms in a few minutes by day or night. There are fourteen fire plugs around the buildings, on the main of the East London Water Works, with hose and turn-cock at hand, so that ample means of extinguishing fire exist on the premises.

But to return to the manufacture. The coating being thoroughly dry, the cloth is then taken to the "rubbers" whose business it is to remove all inequalities from the surface and make it perfectly smooth. This is done by the "rubbing machine," (an ingenious contrivance of M. Eagles, the manager,) by which the cloth is made to pass between two rollers revolving in opposite directions. These rollers are covered with pumice stone, and do the work completely and expeditiously, which, till lately, was done by hand at great expense of labor. The "coating" and the "rubbing" being repeated four, and in the case of heavy goods, five times, the cloth is ready for the "paisters." The "painting rooms" contain machines similar to the "mills;" but instead of a drum they have a roller at each end, over which the cloth passes slowly, and a man at each side supplies the paint, "meeting each other half way." Dependant partly on the colours, and partly on the article to be produced, is the number of coats of paint to be applied. Sometimes two will be sufficient, at other times four are necessary. The last coat receives several applications of a peculiar elastic enamel, chiefly of copal varnish, to protect it from the action of the atmosphere.

At this stage of the process the edges of the cloth are rough and have to be trimmed, and the seam by which the ends are sewn together has to be cut. This is done by a machine called the "Guillotine," and we now follow the cloth to the "grainer." This latter, and to the ordin-

ary leather cloth, finishing process, is done by a remarkably beautiful iron machine, having two rollers, the upper one being of polished iron cut obliquely on the surface, the other one of paper. Between these two rollers the cloth passes twice, and receives its external resemblance to morocco leather. There are six machines used for this finishing process, and others for embossing from the small diamond to the large mediæval pattern. The latter consumes much more time in passing through the machines. The cloth is now stamped with the trade mark, labelled, and rolled up ready for transmission to the warehouse in Cannon Street West.

On looking at the pieces when finished, one is struck by the extreme cleanness of the inner side after passing through so many soiling operations; this is owing to the practical skill with which the men handle the cloth, and to the agility with which they remove it from the several machines, and carry it to the drying rooms. While watching the process, we thought that in many respects, it was similar to the tanning with sumach, from the leaves and stalks of the *Rhus coriaria*, by means of which skins are made into morocco leather. As the leather cloth can be made permanently soft and elastic by the oily matter combining with the texture of the cloth, as it does with the fibres of the skin, the imitation is complete and successful.

There is another room in this establishment, specially interesting to the artist, where the cloth is printed in gold and colours, in designs which are really chaste and beautiful, and which, when used for the furniture and hangings, adorn rooms with something of oriental splendour. Here, too, there are table-covers with floral borders rich in colour and choice in grouping, with centre-pieces, which, as specimens of decorative art, are very effective. Many of these will be displayed at the International Exhibition, and, we doubt not, will excite both surprise and admiration.

The mixing room is a kind of *sanctum* of the manager's, and we suppose that from the skill with which the colours are prepared arises much of the excellence of the company's manufacture. In a room adjoining there are sixteen color-grinding mills, constructed on the American principle, and worked by machinery, as indeed almost everything on the premises seems to be. The machine which sets all in motion is a high-pressure double cylinder engine of 50-horse power made by Woods, of Halifax. There are three immense Cornish boilers by Hill, of Heywood, which have been tested to a water pressure of 130 lbs. to the square inch and represented 60 horse power. One of these is sufficient to work the engine by day and heat the drying rooms by night. We observed that, by the generosity of the company, a part of their premises had been given for the use of the Fifth Es-

sex Rifle Volunteers, the drill-room and armoury are magnificent apartments, such as are seldom seen devoted to such a purpose.

A writer in a very useful work on the "Manufactures of Great Britain," asks somewhat triumphantly, "What substitute could be found for leather? a substance at once durable and elastic, affording a protection from wet and from cold, capable of being formed into innumerable useful articles, and susceptible of a high degree of ornament, and supplying lining to our carriages and covers to our books." This book was published in 1848 under the direction of the "Committee of general literature and education," and now in 1862, we have a substitute answering all the requirements here specified.

As to protection from wet and cold, the whole American army is equipped in leather cloth in the shape of capes, leggings, and knapsacks, our upholsterers can vouch for its durability and elasticity. The useful articles into which it can be made, and the degree of ornamentation it can receive, are becoming every day more manifest. We line our railway, our street carriages, and our hats with it; and as to our books, if they are not covered with it they ought to be. Truly our progress in art and science is defying all prediction as to what we may not accomplish, and rendering absolute many of our familiar proverbs, and none more strikingly so than that "there is nothing like leather."—*Mechanics' Magazine*.

**THE DUST HEAPS OF LONDON.**—The contents of every dust bin in this vast London are carried away periodically. The dustman receives a small gratuity from each householder, and when he has collected a cart load, he demands another shilling at the gate of the Paddington wharves as he deposits it within their precincts. A dust heap is very valuable to the contractor, and a large one is said to be worth four or five thousand pounds. It has to be sifted, sorted and disposed of. We can give but a slight idea of its miscellaneous contents. Its chief constituent element is cinders, mixed with bits of coal, from the carelessness and waste of thousands of servants, which the searchers pick out of the heap to be sold forthwith. The largest and best of the cinders also are selected for the use of laundresses and braziers, whose purpose they answer better than coke. The far greater remainder is called breeze, because it is the portion left after the wind has blown the cinder dust from it, through large upright iron sieves, held and shaken elbow high by the women who stand in the heap, whilst men throw up the stuff into the sieves. The breeze and ashes also are sold to the brick makers, the ashes are mixed with the clay of the bricks, and the breeze is used as a fuel to burn between their layers.

But the heap likewise includes soft ware and hard ware. The former includes all vegetable and animal matter—all that will decompose.

All these are carried off to be employed as manure. Stale fish and dead cats come into this list—the skins of the latter being stripped off by the sifters, who can sell them for fourpence or sixpence, according to their colour, white being most in request. The "hardware" does not merely mean broken pottery, though of this there is great abundance. Part of the pottery is matched and mended by the women who find it, and becomes their perquisites; the rest, with the oyster-shells, is sold to make new roads. But hardware in the dust heaps means rags, which go to the paper makers; bones, which go to the bone boilers; old iron, brass and lead, to salesmen of those metals; broken glass, to old glass shops; old carpets, old mattresses, old boxes, old pails, old baskets, broken tea-boards, candlesticks, fenders, old silk handkerchiefs, knives, and salt cellars, not forgetting old shoes, which go in baskets to the "translators," who turn old shoes into new; everything in short that the householder has thought "not worth mending," besides many a wasteful addition which the masters never knew, from mansions where recklessness and extravagance bear rule. Some of the contents are the sifters' perquisites—a certain amount of cinders, and as much paper and wood as they can carry, and corks of bottles, by which alone some boast they can find themselves in shoe leather: pill boxes also, and gillipots, are their lawful property. Jewelry, silver forks and spoons, and money, are occasionally found, and too often appropriated by the finder. One day a check for a considerable sum was discovered among the waste paper.

**THE ROOK AND THE CATERPILLAR IN LUSS GLEN.**—A few weeks since a colony of caterpillars made an unwelcome lodgment in the beautiful oak copse in Luss Glen, the property of Sir James Colquhoun. In the course of a short time the trees, covering an aggregate space estimated at thirty acres, were completely stripped, and the trunks are now as bare of foliage as they are in the heart of winter. The hand of man was perfectly helpless against these pests, which marched forward, or rather which were eating their way onward, millions strong, and the utter destruction of this beautiful glen seemed only to be a question of time. At this stage a new adventurer appears on the scene; for it fortunately so happened that a wandering family of rooks flying over the glen, at once discovered that of which they were in quest—viz., rations in immeasurable abundance. They commenced an assault upon the caterpillars at once, and having dined most heartily, they generously departed to make proclamation to all the rook brotherhood of the land of Goshen upon which they had lighted. Although the nearest rookery is eight miles distant, an advanced guard set out from it without a moment's delay, and was immediately followed by the whole force of the

rookery. By some extraordinary telegraph other crow communities picked up the tidings, and within a day or two it is believed that every rook within a circuit of twenty miles had found his way to the grub feast in Luss Glen. Our informant, who witnessed the scene in the beginning of the week, states that the glen and the fields around it are blackened with rooks, and that the caterpillars have fairly met their match. The birds commence the assault by the earliest streak of morning light; and after making a copious breakfast, they retire to the fields for rest and digestion, returning to the feast time after time until darkness covers the land, and they can eat no more. The rooks which live farthest from the spot have deserted their ordinary homes for the time being, and have pitched their tents in the glen, where it is presumed they will remain as long as there are grubs to feed them. As it is, the progress of the caterpillars has been completely checked since the birds have commenced in earnest, and it is believed that before long they will have exterminated these destructive insects. The rooks are ably seconded by a corps of jackdaw auxiliaries, and indeed they have allies in most every bird that flies; being the most hungry of the assailing force in Luss Glen.—*Glasgow Daily Herald.*

**TAKE CARE OF THE FEET.**—"Of all parts of the body," says Dr. Robertson, "there is not one which ought to be so carefully attended to as the feet." Every person knows from experience that colds, and many other diseases which proceed from colds, are attributable to cold feet. The feet are at such a distance from "the wheel at the cistern" of the system, that the circulation of the blood may be very easily checked there. Yet for all this, and although every person of common sense should be aware of the truth of what we have stated, there is no part of the human body so much trifled with as the feet. The young and would-be genteel-footed, cramp their toes and feet into thin-soled, bone pinching boots and shoes, in order to display neat feet, in the fashionable sense of the term. There is one great evil, against which every person should be on their guard, and it is one which is not often guarded against—we mean the changing of warm for cold shoes or boots. A change is often made from thick to thin-soled shoes, without reflecting upon the consequences which might ensue. In cold weather boots and shoes of good thick leather, both in soles and uppers, should be worn by all. Water-tights are not good if they are air-tights also; India-rubber over shoes should never be worn except in wet splashy weather, and then not very long at once. It is hurtful to the feet to wear any covering that is air-tight over them, and for this reason India rubber should be worn as seldom as possible. No part of the body should be allowed to have a covering that entirely obstructs the pas-

age of the carbonic acid gas from the pores of the skin outward, and the moderate passage of air inward to the skin. Life can be destroyed in a very short time, by entirely closing up the pores of the skin. Good warm stockings and thick-soled boots and shoes are conservators of health, and consequently of human happiness.

**WHAT IS DYSPEPSIA?**—With due attention to temperance, exercise, and early hours, you may set dyspepsia at defiance. Neglect one of these precautions, and you lay yourself open to the approaches of the enemy—neglect two of them, and it is hardly possible that you can escape. And above all things, keep this in mind, that no other disease or affection of the body is so stealthy or insidious as dyspepsia. If the first few instances of carelessness or transgression were to be visited with pains and penalties that afflict the patient when the malady has become chronic, few men would be so insane, or so obstinately reckless as to postpone the work of reformation. But the earlier symptoms are rarely of an alarming kind. The appetite is not sensibly affected, though the digestion is impaired; and the complaint seems to be limited to flatulency and heartburn. Such unpleasant sensations, however, can be easily removed. Essence of ginger and fluid magnesia, seldom fail to give relief, and the patient flatters himself that there is no ground for apprehension. But the symptoms do not disappear. They recur with great frequency; and the antidotal doses, though increased, are found to have lost their efficacy. The stomach has now become more seriously deranged. All kinds of food generate acid; and in this stage the patient usually has recourse to the carbonates of soda or potash, which in their turn give a temporary relief, though without in any way arresting the disorder. By this means dyspepsia, like an insidious serpent, has fairly folded the victim within its embrace, and is squeezing him at its leisure. Everything he eats disagrees with him, and seems to undergo some wondrous transformation. That which was served up at the table as haggis, seems converted, two hours afterward, into a ball of knotted tow—a mutton chop becomes a fiery crab, rending the interior with his claws; and every rice-pudding has the intolerable effrontery to become revived as a hedge-hog. After that come nausea and vomiting. You derive no benefit from the food you swallow. From twelve stone weight you dwindle down to ten. Your countenance becomes ghastly, your eyes hollow, and you totter prematurely upon your pins. The mere notion of exercise becomes distasteful. You feel as if you had no strength for anything. You are pensive, moody, and irritable. Your mind loses its elasticity and power; and when you sit down to compose, instead of manly matter, you produce nothing but the dreariest of drivel.—*Blackwood's Magazine.*

### The Points of a Short-Horn Cow.

The following features constitute, I trow,  
The beau-ideal of a shorthorn cow:  
Frame massive, round, deep-barrelled, and  
straight-backed;  
Hind quarters level, lengthy, and well-packed;  
Though wide, fleshed inwards, plumb almost to  
hock;  
Twist deep, conjoining thighs on one square  
block;  
Loin broad and flat, thick-fleshed, and free from  
dip;  
Back ribs "well home," arched even with the  
hip;  
Hips flush with back, soft-cushioned, not too  
wide;  
Flanks full and deep, well forward on the side;  
Fore-ribs well fleshed, and rounded like a drum;  
Fore-flanks that even with the elbow come;  
Crop "barrelled," flush with shoulder and with  
side;  
Girth large and round—not deep alone, but wide;  
Shoulders sloped back, thick-covered, wide at  
chine;  
Points snug, well-fleshed, to dewlap tapering fine;  
Neck-vein filled up to well-clothed shoulder point;  
Arm full above, turned in at elbow joint;  
Legs short and straight, fine-boned 'neath hock  
and knee;  
Belly cylindrical from drooping free;  
Chest wide between the legs, with downward  
sweep;  
Brisket round, massive, prominent, and deep;  
Neck fine at head, fast thickening towards its  
base;  
Head small, scope wide, fine muzzle, and dished  
face;  
Eyes prominent and bright, yet soft and mild;  
Horns waxy, clear, of medium size, *unfiled*;  
Tail fine, neat hung, rectangular with back;  
Hide soft, substantial, yielding, but not slack;  
Hair furry, fine, thick-set, of color smart;  
Udder well forward, with teats wide apart.  
These points, proportioned well, delight the eye  
Of grazier, dairy-man, and passer-by,  
And these to more fastidious minds convey  
Appearance stylish, feminine, and gay.—*Mr.  
Carr, of Stackhouse, in the "Highland So-  
ciety's Journal."*

A SAND STORM IN CHINA.—Extract from a  
private letter, dated, Tien-tsin, March 31, 1862:  
—"We had an awful dust, or sand storm, last  
week, which kept us in darkness or nearly so  
for three days. It was the most fearful looking  
thing I ever saw; particularly so at its com-  
mencement, at about three o'clock in the after-  
noon. In five minutes it was pitch dark, and  
we had to light candles. This lasted three  
hours, when the wind increased. 'Tis almost  
impossible to describe it. The very smallest,  
finest, sand seemed drawn out of the earth by  
electricity, and penetrated everywhere. We

all looked like red Indians, and once or twice  
during the first hours, when it was so intense,  
if the sun got a chance through a break, the  
world seemed on fire, then total darkness  
again; and so it continued more or less for  
three days. Very many of the Chinese who  
were at work in the fields perished, as they  
could not find their way home, and died for  
want of shelter. A party came in from Peking  
more dead than alive, and it is a wonder how  
they reached, for they scarcely knew what they  
did or how they escaped. Sand storms are not  
unusual here, but nothing like this has occurred  
for nearly half a century. At Taku the Chinese  
suffered severely, but Europeans seemed to  
have escaped most wonderfully everywhere.—  
The foreign shipping also, both inside and out-  
side the bar, were but little damaged, whilst sad  
havoc took place among the Chinese, both as re-  
gards their lives and property."

THE SPARROW A SCAVENGER.—Nobody will  
deny that the city sparrow is a scavenger, ay,  
and a "regular dustmen" too. There is very  
little of the Adonis about *him*! Washing and  
bathing are unknown, uncared-for-luxuries. He  
glories in dirt. Plump as an alderman, he  
rather waddles than hops, and pays far more at-  
tention to his stomach than to his *personnel*.—  
This last shows sad negligence. Suiting him-  
self to his company and his situation, he is rare-  
ly in a state of repose. Observation tells me  
that eating, drinking, bustle, noise and confusion  
are his strong points. His life is one continued  
round of dissipation. Early and late he may be  
seen slily stealing into some "likely" place  
where he may discover something for his inside.  
Up to every move, deeply read in the physiog-  
nomy of butchers' boys, vagrants, and birds' en-  
emies generally, he is never caught napping.—  
Wide-awake to them all, he cunningly watches  
his opportunity, slips in, commits theft, steals  
out, and is "gone" almost before he is seen.—  
And how thoroughly does he relish stolen prop-  
erty. Boys, girls, and birds, are all alike in this  
respect, I fear.

Stolen sweets are always sweeter,  
Stolen kisses much completer,  
Stolen looks are "nice" in chapels,  
Stolen, stolen be your apples.!

So sings the poet. I have neither the wish  
nor the power to contradict him.—WM. KIDD,  
*in the Queen.*

HOGS AND CURCULIO.—It is the practice of  
many to allow their hogs to run in the orchard  
and gather up all the fruit as it falls. In this  
way the insect is not allowed to leave the fallen  
fruit and perpetuate its species in the ground.  
If no hogs are about, the fruit should all be  
picked up and destroyed before the insect leaves  
it.

**PRESENTS FROM HER MAJESTY TO THE ZOOLOGICAL GARDENS, REGENT'S PARK.**—A short time ago her Majesty received twelve or fourteen beautiful Brahmin bulls and cows, as a present from India. Desiring that our Zoological Gardens should participate in the gift, Mr. Bartlett was last week directed to proceed to Shaw Farm, in the Home-park, at Windsor, and he there selected from the splendid herd a male and female—the former a pearly grey and the latter a creamy white—both very fine animals. Her Majesty also presented a wild sheep of North Africa (female), called the *aoudad*, the society being already in possession of a male of the same species.—*London Field*.

**BREEDING FROM YOUNG SOWS.**—The *Maine Farmer* says "it is quite common to breed from young sows, say full pigs, to come in with a litter of pigs when one year old, a practice to be utterly condemned, and if continued in the same family for a few generations of the swine, they will be found to dwindle down from three or four hundred hogs to two or three hundred. It is much better to keep the sow three or four years, or even much longer. They have been kept some fifteen years to advantage. The hog is some years in his natural state in maturing. It is a fact well known, at least to every Irishman in the "ould" country, that pigs from old sows will grow into hogs some thirty or forty pounds heavier than those from young ones.

**TIMOTHY MEADOWS.**—Care should be taken in cutting timothy not to cut too close, as the roots of this grass are bulbous, and if cut too close or feed too close, the top of the bulb is injured and the wet causes it soon to decay and die. Timothy meadows should always be rolled in the spring to secure as even a surface as possible.

## Editorial Notices, &c.

---

**THE LONDON QUARTERLY REVIEW**—July, 1862. Contents; Memoirs of Sir Marc Isambard Brunel, a most interesting biography; Sussex; Lives of the Archbishops of Canterbury; The Volunteers and National Defence; English Poetry, from Dryden to Cowper; The International Exhibition; The Hawaiian Islands; and The Bicentenary.

**THE EDINBURGH REVIEW**,—July, 1862. Contents; The Explorer of Australia, an article of great and universal interest; Wellington's Supplementary Despatches; Sir G. C. Lewis's Astronomy of the Ancients; Earl

Stanhope's Life of Pitt; Troyon's Lacustrine Abodes of Man; Weber's Gleanings from German Archives; Iron, its uses and manufacture; Remains of Mrs. Richard Trench; and Dollinger on the Imperial Power.

These numbers commence new volumes, affording a good opportunity for new subscribers to procure those valuable productions, which are issued by LEONARD SCOTT & Co., 79 Fulton-street, New York, within two or three weeks of their original publication in London, and at one third of the English price.—The above, with the North British and Westminster Reviews, and Blackwood's immortal Magazine, can be had for the unprecedentedly low charge of \$10 per annum! Or, they can be subscribed for separately, each Review, (quarterly) \$3, and *Blackwood*, (monthly) \$3 *per annum*. BLACKWOOD for August is, as usual, exceedingly interesting.—We are happy to know that these British periodicals, of the very highest literary and scientific character, are, in consequence of these cheap and well executed reprints, being extensively circulated throughout the United States and the British Provinces.

**SALE OF PURE-BRED STOCK, SHEEP AND PIGS**—We have much pleasure in calling the attention of our readers to Mr. Stone's Advertisement in the present number. Mr. Stone merits as an importer and breeder of Short-horns and Herefords, and of the most approved varieties of sheep and pigs, are now too well known and appreciated to need any recommendation from us. He has spared neither time nor expense in getting from Britain the best specimens, and no one can visit his farms at Guelph and observe the management carried on there without being convinced that their owner is a man in whose judgment and integrity the public may safely place confidence. Mr. Stone's animals, whether cattle, sheep, or pigs, are alike a credit to himself and to Canada: and that his brother farmers think so is shown by their having elected him President of the Agricultural Association of Upper Canada for the present year. We trust that the approaching sale at Moreton Lodge will be equally successful with those of previous occasions.

## MORETON LODGE NEAR GUELPH, C. W.

### Important sale of Imported & Pure Bred SHORT HORNED CATTLE

Cotswold, Leicester and South Down Sheep,  
Berkshire and Small White breed of Pigs.

Mr. W. S. G. Knowles, begs to announce that  
he has received instructions from Fred. Wm.  
Stone, Esq. to offer

### FOR SALE. BY AUCTION ON WEDNESDAY, 15TH OCTOBER NEXT

At Morton Lodge, near Guelph, Canada West  
Thirty Imported and Pure Bred

### SHORT HORNED CATTLE, One Hundred and Fifty Imported and Pure Bred COTSWOOD, LEICESTER & SOUTHDOWN SHEEP,

Consisting of Rams, Ram Lambs, and Ewes.  
And 25 Berkshire and small White Breed of

**PIGS**, of different ages.

The Short Horns are Imported and bred from  
some of the most fashionable Herds, such as  
Capt. Gunter's, Col. Kingscote's Messrs. Tan-  
queray's Ambler's Bolden's, Sandy's, Jonas  
Webb's, Smythe Owen's and other eminent  
Breeders. The Cotswood Sheep are imported,  
or bred from Imported Stock. From the flocks  
of Messrs. Ruck, Slatter, Brown, Langston,  
Gare, Wakefield and other celebrated breeders.  
The Leicester's imported from Mr. Pawlett's  
flock, and the Southdowns, imported and bred  
from the celebrated Buckland and Babraham  
Flocks of Sir R. Throckmorton and Jonas  
Webb. The Berkshire pigs, from the finest  
Buckland Stock. The small Wheat Breed from  
Capt. Gunter's

Catalogues, with Pedigrees, and othe  
particulars, are now in preparation, and will  
shortly be issued, and may be had on application  
to Mr. Knowles, or of Mr. Stone, of Guelph.

Guelph, 8th Sept. 1862.

### EAST RIDING YORK

Agricultural Society Fall Show,  
AT WELLINGTON HOTEL GROUNDS,  
MARKHAM VILLAGE, 9th October, 1862.

All Entries to be made by the evening of the  
9th, or to be peremptorily excluded.

A. BARKER,  
Secretary.

### Horse Infirmary and Veterinary Estab- lishment, Corner of Bay and Temperance Streets, Toronto, C. W.

A SMITH, Licentiate of the Edinburgh Vet-  
erinary College, and Veterinary Surgeon to  
the Board of Agriculture of U. C., begs to return  
his thanks to the Public generally for their sup-  
port since opening the above mentioned establish-  
ment, and respectfully solicits a continuance of  
the same.

And also begs to announce that Veterinary  
Medicines of every description are constantly  
kept on hand:—Such as, Physic, Diuretic,  
Cough Cordial, Tonic Condition, and Worm  
Balls and Powders. The constituents compos-  
ing the Cough-balls, have been found (by Pro-  
fessor Dick, of Edinburgh) most serviceable in  
alleviating many of the symptoms of Broken-  
wind or Heaves in Horses. Colic Draughts, &c.,  
a mixture which owners of Horses should always  
have beside them.

Liniments for Sore-throat, Sprain, Curb,  
Spavin, Ringbone.

Blistering Ointments. Liquid and sweating  
Blisters.

*Horses bought and sold on commission.*

Toronto, Aug. 30th, 1862.

### THOROUGH-BRED STOCK FOR SALE

THE Subscriber has for sale DURHAM and  
GALLOWAY CATTLE, LEICESTER,  
COTSWOLD, and LINCOLNSHIRE SHEEP,  
Male and Female 10 Durham and Galloway  
Bull Calves—price from \$100 to \$200; 20  
Shearling Rams, weighing from 230 to 285 lbs.  
each—Price from \$50 to \$100 each.

JOHN SNELL,  
Edmonton P.O., C. W

Four miles from Brampton Station G.T.R.

### FOR SALE!

### Ayrshire Cattle, Leicester Sheep, and Berkshire Pigs.

THE Subscriber offers several Young Bulls,  
Heifers and Cows, on very Liberal Terms.  
Specimens from his *Prize Herd* will be on Ex-  
hibition at Toronto, if all's well.

P. R. WRIGHT, Cobourg, C. W.

Aug. 30th, 1862.

6-mos.

### THOROUGH BRED STOCK FOR SALE.

THE SUBSCRIBER has for Sale Durham  
and Galloway Cattle, male and female.

Leicester, Cotswold, Lincolnshire, Down and  
Cheviot Sheep; Cumberland and Yorkshire im-  
proved Pigs. All imported stock.

GEORGE MILLER,

Markham, June 3rd, 1862.

6t.

**TO BE SOLD BY AUCTION,***On Thursday, Oct. 16, 1862,*

**THE** well-known Herd of **NORTH DEVON CATTLE**, consisting of more than forty head of Cows, Bulls, and Heifers; one hundred and seventy West and Southdown Ewes and Rams; pure blooded Essex Pigs, in pairs fit for breeding.

Catalogues of description, with pedigrees, may be had fourteen days before the sale, on application at the office of the *Galt Reporter*, if by letter, prepaid. Credit of 12 months may be had on approved endorsed paper.

**THE SPLENDID FARM,**

Consisting of upwards of **THREE HUNDRED ACRES**, to be sold by private bargain, on accommodating terms.

## The Provincial Exhibition.

The Seventeenth Annual Show of the Agricultural Association of Upper Canada was held in the City of Toronto, Sept. 23—26th, 1862. The weather throughout being delightfully fine, and the capacious grounds affording ample space for the large amount of Live Stock, implements, &c., together with immense crowds of visitors, the recent exhibition may be pronounced not only a decided success, but, upon the whole, superior to any former occasion. A liberal grant being given by the corporation of the city, the Local Committee were enabled to erect extensive ranges of stables, sheds, &c., of a convenient form and permanent character, which afforded good accommodation for the large amount of fine animals, in all classes, that constituted a striking and pleasing characteristic of the show. We are indebted to the City Daily Press, and other sources of information, for the following Report. The official Prize List, which will appear in our columns as soon as the final corrections are made, and the material made up, will inform the reader of the awards of the judges. In the mean time this information has been communicated to the public by the Daily Press of this city, involving a large amount of trouble and expense to the proprietors of those journals. Our list will contain the necessary corrections and additions.

## HORSES.

The exhibition of Horses was not only unusually large, but, upon the whole, of a quality never before equalled at our Provincial Shows. That is to say we never had before so large a number of horses, possessing so superior excellence; a remark that will apply to almost every other department of live stock; thereby indicating in an unmistakable manner, a healthy state of progress.

Of Blood Horses, there were 24 entries in the different sections, comprising several good specimens; but it must be confessed that on the whole there was a deficiency in this class. In the thorough-bred Blood Mares and Fillies the competition was not extensive; Mr. White, of Bronte, succeeded in carrying off the greater number of prizes in this class, and deserves credit for the pains which he has bestowed on the selection of his stud, which ranks among the first in Upper Canada. In the large class of Agricultural Horses, numbering 71 entries, scarcely an inferior animal was exhibited. The Stallions, 4 years and upwards, and also three years, were, with scarcely an exception, particularly good.—There may be sufficient grounds for differences of opinion as to the precise weight and style of horses for agricultural purposes in this country,—but it must be admitted, we think, on the whole, that deep and thorough cultivation of our older and heavier soils cannot be effected by the lighter kind of horses that have been hitherto in ordinary use. The infusion of Clyde blood is regarded with favour by our thorough-going cultivators.

In class third, composing Road or Carriage Horses, a large number of animals were shown. In stallions of four years and upwards more than 20 entered for competition, mostly very superior animals, and highly creditable to the

Province. Mr. Armstrong's horse "*Diploma*," was awarded the first prize. He also succeeded in gaining the Diploma of the Association, as the best horse of any age or breed. Some very fine trotting horses were exhibited in this class, and these belonging to the city of Toronto were worthy of notice; viz.; "*Pathfinder*," the property of Mr. Bond, Sheppard Street; and "*Toronto Chief*," and "*Governor Clark*," belonging to Mr. S. S. Halladay. The Brood Mares, Colts and Fillies, were as classes, decidedly superior. In saddle and carriage horses the competition was limited, and although several good animals were shown, there is, it must be acknowledged, considerable room in this department for additions and improvement. In the class of Heavy Draughts, four years and upwards, it may be mentioned; were five imported horses of great merit. Brood Mares, colts and fillies were also excellent. It short it was the expressed opinion of many competent judges that this exhibition of horses would be, as a whole, with difficulty surpassed by any country.

### CATTLE.

Considered in reference to the effect upon the advancement of the country, it is probable that the annual show of cattle is of more moment than any other portion of the Exhibition.—There is more to be accomplished by competition in this department than in any other. The immense improvements which have resulted from careful breeding, have caused the most energetic and zealous agriculturists to enter into stock raising, as a pursuit which calls forth and rewards all their exertions. And they look with great interest to the annual competition, when they receive the reward of their labours.

The present show of cattle is, as a whole, better than that of any former year, though there were deficiencies in some departments. One misses the fine herd of Devons of Mr. Lock of Yar-mouth, who has betaken himself to the Western States, but the herds of Mr. Tye of Wilnot, Mr. William Scott of New Hamburg, Mr. Courtice of Bowmanville, Mr. Pincombe, of London, Mr. Thomas Allen, of Whitby, Mr. Rykert of St. Catharines, Mr. John Moore of Etobicoke, Mr. J. W. Wilson of Flamboro and others, show that this small but beautiful and useful breed has its supporters among our best stock raisers.

Durhams, Herefords, Devons, Ayrshires, and Galloways have each their advocates, and there was about as keen opposition among them as there is in politics or divinity. In this show, as always, the short-horns maintained their supremacy as the best animals for general purposes, the best for the butcher, and the best to improve the ordinary stock of the country, the largest, and most easily fatted. The Durhams have the majority, but their reign is disputed. Mr. Stone,

of Guelph, the present President of the Agricultural Association, who stands at the head of our importers, (although Mr. George Miller, of Markham, comes very near him,) has lately brought from England a herd of eleven Herefords. He, at all events, does not appear to give weight to the common objection to this breed that they are less kindly feeders than the short horns. The only exhibitors of Herefords were, however, Mr. Stone and Mr. J. R. McMicking, of Queenston.

The Ayrshires, also, had their adherents. The "short horns" pooh pooh them. They were small, they do not make meat for the butcher, but as dairy cattle they are admitted to be unrivalled. They are sent from the country of their original growth, from which they take their name all over England and Scotland. A good judge engaged in the importation of stock told us that if he were about to commence dairy farming he would have no other cattle but Ayrshires. Crossed with Durham also, it is alleged that they suit the butchers well. Messrs. Patrick R. Wright, of Cobourg; John P. Wheler, of Scarboro; R. L. Denison, of Toronto; George Stanton, of Paris; George Morton, of Leeds; John Torrance, of Scarboro; George Scott, of Woburn; Simon Beattie, of Markham; Joseph Boyle, of Flamboro; Hendrie & Co., of Hamilton; and George Miller, of Markham, were the chief exhibitors of this class.

The Galloway cattle have been but a few years introduced into Canada; but they have made extraordinary progress. The number exhibited at the show was very large, and the specimens very fine. This breed does not mix well with the native cattle, but they thrive well in this country by themselves. They are very hardy and the beef is good, but the "short horns" say that they cannot produce such sirloins as their favourite breed. The chief exhibitors of Galloways were Messrs. Snell, of Chinguacousy, Kyle, of Ayr; Auld, of Hamilton; McClain, of Clover hill; James Graham, of Woodbridge; George Davison, of Unionville; George Anderson of Varna; Somerville, of Vaughan; G. Z. Rykert, of St. Catharines; George Roddick, of Port Hope; Alex. Kerr, of London; Arthur McNeil, Woodbridge; John Stuart, Waterdown; John Fleming, Vaughan; John Hunter Exeter; George Miller, Markham; David Mtssenger, Cooksville; and last not least, James Mecalf, Eglington.

The "short horns" are almost too numerous to mention. Almost all the old exhibitors were present, and some new ones. Messrs. Stone, Guelph; Bentley, Cooksville; Bellwood, Newcastle; George Miller, Markham; George Cooper, York; Edward Jones, Thorold; Edward Huggins, Embro; G. D. James, Toronto; John Watt, Fergus; Donald Robertson, Queenston; John Iles, Guelph; John Graham, Paris; James White, Bronte; Simon Shunk, York; G.

Z. Rykert, St. Catherines; Henry Welford, Woodstock; John White, Georgetown; Gavin Craig, Grafton; Thomas Martindale, York; John Betts, Grimsby; John Miller, Pickering, (son of William Miller, of the same;) L. Harrison, Morley, St. Lawrence county, New York; Henry Talbot, Everton; Mrs. Ralph Wade, Cobourg; John E. Conse, St. Thomas; John Foote, Port Hope; James Kirkland, Indiana; George Roddick, Port Hope; M. Jones, Bowmanville; John S. Armstrong, Guelph; E. C. Scarlet, Etobicoke; Hon. John Ross, Toronto; Thomas Stock, Waterdown; N. J. McGillivray, Williamstown, Glengarry; Arthur Hetherington, London; A. Fanson, Bowmanville; H. P. Welford, Woodstock; John Walton, Peterboro; Samuel Hodgskin, Guelph; James Vine, St. Catherines; John Thomson, Whitby; Henry Jennings, Victoria Square; James Metcalf, Eglington; Arthur Hogge, Guelph; John Daw, Yorkville, were among the chief exhibitors. From the extent of this list, and the completeness with which all sections of the country were represented, the reader may easily judge of the universality and extent of the taste for short horns. The English breeders are constantly improving this stock, but it is the impression among our farmers that they fully keep pace with the English movement. Very soon, there will hardly be an unimproved animal to be found in the Upper Province, and the pure bred cattle will by constant renewals with English blood, be kept up to the highest possible standard.

### SHEEP.

The quality of sheep in Canada is also yearly renewed by importations from England. Since the last show Mr. Simon Beattie, of Markham, and Messrs. J. and M. Kirby, of Esquesing, have made additions to their flocks, the former from the stock of Mr. Thorpe and Mr. Robinson, of Yorkshire, and also of Mr. Sandys, of Nottingham, and the latter from Mr. Jardine, of Eastbourn. Great risk is encountered in these importations. Mr. Beattie had a passage of ten weeks; his fodder was nearly exhausted, he lost three animals, and his sheep, Ayrshire cattle, and a blood horse were brought to an extreme point of weakness. His animals exhibited were rather in poor condition, but the thorough-bred horse was evidently a fine one, of *Irish Bird-catcher* blood, raised by the Earl of Howth. Mr. Beattie does not think that better sheep are to be found in England than in Canada, but that it is of the greatest importance to "renew the blood." The fleece in Canada becomes rather finer, but is not so plentiful as in England. Mr. John Snell is the most enterprising breeder of pure sheep in the country, apparently, judging by the number of entries set down opposite his name. Mr. George Miller, of Markham, and Mr. Stone, of Guelph, were very little behind,

however. Mr. Snell does not at present import, but buys largely from importers. Leicesters are the favourite sheep, but Cotswolds, Southdowns, Cheviots, and Merinoes had their advocates. The last named class is coming into very general use, the attraction of 20 cents a pound more for the wool than for that of the best of other breeds being a strong one. There were many entries in this class, Messrs. Jennings, of Cooksville; Miller, of Homer; Rymal, of Ryckman's Corners; Arkland, of Oshawa; Young, of Ryckman's Corners; Row, of Glenmorris; Messenger, of Cooksville; Alfred Jeffrey, of Woodbridge; and Joseph Peers, of Woodstock, being the chief exhibitors.

### PIGS.

The stock was on the whole fine, and considerable improvement was manifest over former years.

### YORKSHIRES.

Of Yorkshire boars there was a very fine display, in which Mr. C. A. Jordison, of Belleville, figures largely. Among the other exhibitors were Messrs. Samuel H. Reeves, of Derry West; Alfred Jeffrey, of Woodbridge; J. P. Wheler, of Woburn; and James Maines, of Brampton. There was an excellent show of Yorkshire sows, the chief exhibitors being the same as of boars.

### BERKSHIRES.

The show of large Berkshires was not very large, but it was choice and good. Mr. George Morton, of the county of Leeds, exhibited a very fine boar of this breed, bred in England, and several large breeding sows of superior size and excellence. Messrs. Henry Ede, of Leskard; John Davey, of the same place; Patrick R. Wright, of Cobourg; John Gibb, of Lindsay; Alex. Gerrie, of Ancaster, and William Wilson, Islington, were among the exhibitors.

A number of other large breeds were exhibited, those of Messrs. Jonas S. Baines, of St. Thomas; P. R. Palmer, of Thurlow, and Cunningham Hastings, Bradford, being especially worthy of notice.

### SUFFOLKS.

Of these small-breed pigs there were several fine specimens exhibited, some of them being imported. Messrs. Francis Winter, of Cooksville; Henry Battell, of Grafton; Simon Shunk, of Concord; Edward Arkland, of Oshawa; Peter Lyon, of Oakville; George Savage, of Burnhamthorpe; John McGlashan, of Pelham; Thomas Mills, of Albion, and Peter Mettler, Jr., of Pelham, were exhibitors in this class.

Of other Small breeds about forty were exhibited, most of them being really fine animals. Messrs. John Malcolm, of Ancourt; James Cowan, of Galt; Thomas McCrae, of Guelph, and Samuel Cameron, of Willowdale, were the chief exhibitors.

## IMPROVED BERKSHIRES.

There were several fine Berkshire Boars and sows shown, a great improvement being evident in this department of the exhibition. The list of exhibitors embraces some of the most extensive agriculturists in the Province, and shows that in the right quarter proper attention is being bestowed upon the raising of this valuable animal. Among the exhibitors were the Hon. John Ross, of Toronto; Messrs. David Buchan and Thomas Penton, of Paris; E. W. Thomson, of Toronto; P. Rose Wright, of Cobourg; R. L. Denison, of Toronto; John Foott, of Port Hope; William D. Jarvis, of Toronto; John P. Bull, of Yorkville; Alex. Gerrie, of Ancaster, and George Morton, of Morton.

Altogether the display of pigs is up to the average, and in some breeds above it.

## POULTRY.

Many thousands derived great pleasure in examining the extensive poultry ranges, which were well filled with every variety of domestic fowl. Several pairs of white Dorkings were exhibited and attracted much attention. Those shown by Mr. Charles Nourse, of Whitby, and John Bogue, of London, were beautiful in plumage, form and size. Messrs. S. Peters, sen., of London, Adam Mathers, of Islington, and John Ker, of Drummondville, were also exhibitors.

Of spangled Dorkings there was a very nice show. Messrs. N. and J. Bethell of St. Catharines; George Miller, of Markham; F. W. Stone, of Guelph; E. W. Thomson, of Toronto; and Edward Arkland, of Oshawa, were among the exhibitors. The birds were all very fine specimens.

There was a good assortment of black Polands on exhibition, some of which were much admired. The exhibitors were the same as in the former varieties, with the addition of Messrs. Jeffrey, of Woodbridge, F. Fergusson, of South Zora, and Henry Girouard, of Hamilton. Of white Polands three handsome specimens were shown by Messrs. John Bogue, of London, and John Ker, of Drummondville. Ten golden Polands were shown, all of them very pretty fowls; and of silver Polands eight were exhibited.

There was quite a keen competition for the prize offered for game fowls, fourteen very handsome birds being exhibited, among the finest are those of Messrs. George D. James, Andrew J. Riddell, Samuel Baird, and R. L. Denison, of Toronto.

Messrs. Peters and Bogue, of London, were the only exhibitors of Jersey Blues.

Of Cochin China, Shanghais, Cantons, &c., there was but a small collection. Mr. Phillip Armstrong and Mr. John Hayden, of Toronto, exhibited some very pretty birds of these varieties.

There was rather an extensive display of

Spanish, Java Black, Bolton bays and grays, Hamburg and Dominique fowls, all of which were minutely examined and excited much admiration.

Of Bantams of both kinds—feather and smooth legged—there was a very choice display, the exhibitors being the same as in the other species of fowls.

There was a large and interesting show of Turkeys, geese and ducks, all varieties being well represented. There were also some very good collections of poultry of all kinds, for the best of which the Association annually bestows liberal premiums.

## IMPLEMENTS AND MACHINES.

This is unquestionably one of the most important departments of the Exhibition, and one that most unmistakably shows the great advancement Canada has made of late years. For a considerable time after the commencement of the Provincial Association most of the Agricultural implements and machines were importations from the States, with here and there a specimen of Canadian manufacture. This state of things became changed by degrees; the American importations gradually became smaller, till at length they nearly ceased altogether. For the last few years the material of this important department of the Exhibition has been almost exclusively Canadian; and we now find mechanics in different parts of the Province—some of them doing business on an extensive scale, having large workshops and manufactories, supplying our farmers and artisans with their requisite tools and implements quite equal in quality and durability to the best productions of the States, and on quite as easy terms. There was a large number of Ploughs of wood, iron, or mixed, constructed on different principles, to meet the varying conditions and special purposes of the art of culture. Among the principal makers are Messrs. McSherry, of St. Davids; G. Morley, Thorold; G. Gray, Stratford; W. Mahaffy, and J. Modeland, Brampton; R. Anderson, Alma; and J. W. McLaren, Lowville; all of whose productions are known and appreciated by the public. Swing, side hill, gang and double mould board ploughs, most of them of excellent material and workmanship, and evincing, more or less, the recognition of the principles of mechanics, lightness of draught combined with sufficient weight and strength, and neatness and thoroughness of work. In other implements and machines belonging to the daily routine of the farm, such as mowers and reapers, thrashers and separators, grubbers, harrows, &c., a similar improvement was discernable. The premium list will show which of these articles the judges considered the best.

Of late years steam has attracted much attention as a motive power in Agricultural operations, and it must be confessed that the investi-

gations and experiments made have been attended with a most encouraging degree of success. There were three steam engines on the grounds adapted to agricultural purposes, from Messrs. T. Zealand, Port Hope; Beckett & Co., Toronto; and Ganson & Co., Dundas. The latter has a six inch cylinder with an eleven inch stroke. The boiler is so constructed that a large heating surface is secured, and a saving of fuel thereby effected. The weight of the machine is nearly two tons, and its price \$650. These engines appear to be strongly made, and well adapted to put into operation thrashing machines, chaff and root cutters, and other implements or machines. The plough and cultivator have not, as yet, been propelled by steam in Canada, but will probably be so ere long on the larger and better cleared farms in the more advanced districts. The number of fanning mills was large, several of them evincing much skill and ingenuity in their construction. Among the makers may be mentioned Mr. Stephens, of Port Hope; whose machines have some special contrivances for the more effectual cleaning of the seed of all impurities. Mr. Harris's (Beamsville) machine for cleaning clover does its work expeditiously and effectually. Of root cutters, Mr. Doner's of Cashel, is of simple construction, and the turnip is crushed by being forced through a narrow passage, and in winter when the roots are hard the slices fall into pieces small enough for feeding sheep. Mr. Leigh, of Aurora, has a similar machine, but in order to cut the turnip into slices, it has a number of little upright knives in the cylinder, which divide the pieces just cut by the larger knife. Messrs. Maxwell and Whitelaw, of Paris, showed a machine that would cut either coarse or fine by turning different ways, so as to reduce the roots for the consumption of sheep or cattle. The same firm also exhibited a very effective straw cutter adapted to hand, horse or steam power.

We may mention that the churns were numerous and several of them evinced much ingenuity of construction. In these articles too, much improvement has been made of late years. Among the exhibitors were Mr. Kinney, of Brantford; Mr. Hummill, of Cornwall, who had a double acting churn; Mr. E. Lawson, Toronto; Mr. J. McLean, Scotland, C. W.; Dun & Jones, Huron; Mr. Thomas Head, Copetown.

There were several excellent thrashing machines on exhibition, some of them of very elaborate workmanship. Mr. J. Hall, of Oshawa, had a clover thrashing machine which thrashes out the seed directly from the straw by once going through. He also exhibited a grain thrashing machine and fanning mill combined, very elaborately got up. Mr. Jas. Milne, of Scarboro', showed an ingeniously contrived thrasher, combining, it is claimed, several improvements, price \$190, four horses can work it and thrash 300 bushels a day. The competit

ion in reapers and mowers was not great, but the specimens shown were good. Messrs. Paterson, of Belleville, had a combined machine of superior workmanship and construction. The driver without changing his seat, can elevate the cutting bar a distance of five inches, so as to mow at that or any intermediate distance from the surface. In case of stones or inequalities the cutting apparatus can be readily elevated, price \$155. Messrs. Savage, of Hamilton, exhibited a machine showing much ingenuity and some novelty, and is well thought of by practical men. Mr. Lawrence, of Palermo, has affixed to his very excellent machine a spring lever, by which he lets the finger board readily down after it has been raised. These indispensable machines are now made in the Province of equal excellence, including efficiency of action, durability and cost, with any produced by American manufacturers. Among the novelties connected with agricultural machinery may be mentioned the exhibition of a drain tile machine manufactured by Hamilton & Sons of Toronto. This is the first specimen we have seen of Canada manufacture, and judging from its appearance it promises to be an efficient production, adapted by a series of dies to tiles and pipes of different sizes. As draining is so essential to every plan of agricultural improvement on most soils it is devoutly to be hoped that this Canadian machine will in practice meet the wants of the farmers.

#### THE FOREST CULTIVATOR.

This is a new implement exhibited for the first time at the late Provincial Agricultural Exhibition. Its object is the better and more easily cultivating newly cleared land, while it is still encumbered with stumps and roots. All who have had to do with clearing land, (and which of our readers has not?) know the difficulty of getting a sufficient tilth of loose earth on the surface of the forest (when newly cleared) so as safely and evenly to bury the seed. The only implement to be depended on is the drag; this does well enough provided rain follows immediately after the grain is sown; but if a long spell of dry weather intervenes, as was the case in this Spring of 1862, the crop comes up unevenly, and at harvest there appear on the ground two crops intermingled, one ripe and the other green. Again, all farmers are well aware of the all but impossibility of getting in a second crop of grain, after the first crop. The land being virgin soil, and very rich, would of course bear several grain crops following with comparatively little injury; but the drags will not at all times pull up the old stubble, and the weeds of the previous year, and to plough with an ordinary plough is impossible. The farmer is, therefore, obliged to seed down with his first crop, and allow the land to remain in pasture until the roots are sufficiently rotten to admit the plough, and even then constant difficulties occur.

It is to meet all these cases that the Forest

Cultivator has been constructed. The shears, (three in number) all slope backwards from the frame of the Cultivator, at such an angle, that when the machine is dragged forward and strikes a root, the part of the cultivator so opposed does not check and stop, but rises over the obstruction, and is ready again to bury itself in the ground by its own weight as soon as the obstruction is passed.

Each of these shears is armed with small wings or turn furrows, which rip up the earth, sod, stubble, or what not, and throw it abroad. The machine is so arranged as for the one shear to cover the other in its passage sufficiently to make clean work and cut all before it.

The shears being three in number, and placed at nearly an equilateral triangle with each other, can scarcely all strike the same object at once, if one is out of the ground, the others are the more deeply imbedded, and so it travels on, moving and tearing up every available spot of earth, rising over roots as they occur, and if a stump is in the way the cultivator frame being like an A drag, only strikes it at an angle, and glances off.

The space covered by it is three feet in breadth, and we are assured by those who have seen it at work, that it made as good work going twice over the ground, as the drag does in five or six time, besides being more speedy than the drag, it buries the grain so deep that the even coming up of the crop is all but a certainty.

By its use the man struggling with all the difficulties of new land can realize two or three crops of grain before seeding down,—the full advantage of which fact can only be realized by the struggling improver of the forest.

The implement is made very heavy and strong as it acts mostly by its weight. To look at it it appears too heavy for a yoke of cattle, or a span of horses, but we are assured it is not found to be so in practice. In new land the obstructions are so numerous that the machine has no time to bury itself so deeply as to render it difficult to move. There are few or no shocks on the cattle or horses, and the holder has a much easier berth of it than one would suppose possible.

The machine in question was manufactured by the inventor, Mr. Cull, of this city, for his own use, and was plain and strong, and not set off by the usual amount of paint and varnish,—hence, except among practical persons, it attracted less notice than many other agricultural implements which were smarter in appearance; but the real practical farmers who have gone through the trouble of cleaning up a farm fully appreciated it, and no doubt, when such machines come to be manufactured and offered to the public, will make a liberal use of them.

One of the shears on a somewhat larger scale makes an excellent plough for the same purpose as before noted, when fixed in a suitable beam, and is well adapted for places where the full cultivator could not work.

We wish the implement a full measure of success as we do every other improvement in agricultural matters and machines. It was awarded an extra prize.

## AGRICULTURAL PRODUCTIONS,

### GRAIN, SEEDS, ROOTS, &c.

This important department of the Exhibition in point of *quantity* at least was much inferior to some previous occasions. A large number of persons having entered their articles, failed to exhibit them. This was the case to a much greater extent than was ever known before, and it occasioned considerable inconvenience to the parties having superintendence of the arrangements. It is to be hoped that some means will be devised another year to prevent, or at least greatly mitigate this evil, which occasions alike much inconvenience and unnecessary outlay. In the English national Shows exhibitors not only pay for space, but are actually fined in case they neglect to bring their cattle or articles forward, unless occasioned by some uncontrollable cause. Although it would be difficult, perhaps, to enforce so stringent a regulation at our Provincial shows, it is hoped that for the future persons entering articles will not do so without due consideration, and not allow trifling causes to prevent them being exhibited.

There were several of the samples of wheat, oats, rye, peas, buckwheat and Indian corn that clearly indicated first rate quality, and careful cultivation. The late season was in some respects, unfavorable to the pursuits of the farmer, and considering the severe drought which prevailed in Spring and early Summer throughout the western section of the Province, the quality of the cereals exhibited was better than could at one time have been anticipated.

Amongst the novelties of the grain department, we notice that the Canada Company, with their usual liberality where agricultural matters are concerned, have introduced a sample of two bushels of the celebrated "Pedigree Wheat," grown by Mr. Hallett, of Brighton, England. This is a splendid sample of Red Fall Wheat, which by repeated selection has far surpassed its original stock; indeed, if we are to believe the pictorial representation of the wheat, and there seems no ground for doubting it, the ears have attained the enormous size of eight inches and a half in length, and corresponding breadth and size. Its prolific nature is such that Mr. Hallett states in his printed description, that he has succeeded in producing a yield of over one hundred bushels per acre. The wheat only arrived from England on the 22nd inst., almost too late to give it a fair trial for this year; but still several of our first agriculturists have sown small quantities of it. The com-

pany are distributing what they have, and we hope it may next year be sown by the first week in September, and thus have a better chance than it is likely to get this season.—The price of the wheat was two guineas sterling per bushel, besides the cost of importation by express.

The Roots, whether regarded as to quantity or quality, did not come up to the ordinary standard of a Provincial Show. This no doubt arose chiefly from the unfavourable character of the season, and the somewhat earlier period of holding the show:—a week or two at this period will often produce great changes in turnips, beets, carrots, &c. Notwithstanding there were several specimens of cabbage, khol rabi, varieties of turnip and other agricultural roots, which indicated excellent quality, well grown and proportioned; and we trust next year, under more favorable circumstances, that this important department will assume its wonted dimensions and excellence. Root culture, and the proper maintenance of our now numerous breeds of improved stock, must proceed together. The potatoes were very fine, and apparently free from disease, which, however, has made its appearance, we trust but slightly,—in several localities.

#### FRUITS AND FLOWERS.

The show of fruit is not larger than in former years, but in regard to quality it is superior to anything exhibited before. There have been great improvements during the last few years in the growth of pears, peaches, nectarines and grapes, and the specimens exhibited in all these classes were magnificent. Of apples there were, of course, full store. The Niagara peninsula, lying between Lakes Erie and Ontario and the Niagara River, may be safely described as the fruit garden of Canada, and it took a very large proportion of the prizes at the Show. But other localities were not far behind. Hamilton City, protected by hills from the cold winds, is evidently favourable for the growth of fruit. Mr. John Freed, of that city, took the first prize for peaches, and Messrs. Bruce and Murray, nurserymen, took a number of prizes in grapes, nectarines and pears. Mr. H. M. Switzer, of Palermo, also took the first prize for white grapes grown in the open air. Mr. Geo. Leslie, of Toronto, took a number of prizes, and Mr. Stibbard, of Eglinton, made a good show in apples. But Mr. D. W. Beadle, of the St. Catharines nursery, a thoroughly educated horticulturist, Mr. W. H. Read, of Port Dalhousie, the great grape grower, Mr. S. J. J. Brown, H. J. Brown, and Mr. R. N. Ball, the largest growers of fruit in the township of Niagara, and Mr. Warren, and Mr. Currie also of Niagara, more than sustained the credit of

the district across the lake. Mr. Read's grapes drew all eyes. He has entered into numerous experiments in raising grapes from the seed, and in crossing the native Canadian growth with improved varieties. By joining the native to the Black Hamburg he has obtained an enormous round black grape of fair quality. He has nearly two hundred different varieties coming forward from the seed, and is sanguine of being able to obtain an open air grape which will make good wine, and be better for the table than any now grown. He has bestowed infinite care and labour on this work, and deserves the highest medal that the Provincial Association can give to him. He and the other open air grape growers agree that the Delaware is the best grape now grown in Canada. It is small, but sweet and highly flavoured, and is a large bearer. Its size may be improved by judicious culture. All the grape growers are sanguine that they will yet be able to produce a grape which will make wine of home manufacture an article of daily consumption in Canada.

Of grapes grown under glass the exhibitors are yearly increasing, and the finest specimens yet seen were at this exhibition, reflecting great credit on the skill and persevering industry of their cultivators. In open air grapes the competition was keen, and several new sorts introduced which bid fair to displace some of the older varieties, such as the Clinton, Isabella, and Catawba.

The apples were numerous and generally of excellent quality. We would suggest to the growers of the finest and best keeping sorts, the desirableness, in a bountiful year like this, of putting them carefully into barrels, and shipping them by the Montreal steamers for England, where they would be certain to command a good, and we believe, remunerating price.

The collection of Pears was large and of superior quality. Messrs. Ellwanger and Barry, of Rochester, N. Y., had some very fine specimens of this delicious fruit, as had several of our own growers, who carried off a great many of the prizes.

The season is highly favourable for ripening and bringing to a high state of perfection the Peach, and the specimens shown were superior in quality and flavour to any heretofore exhibited. The principal growers were from Niagara, St. Catharines, and Hamilton. It is a fact worth recording that some fine peaches were sent from Goderich, showing that in favourable seasons the area for growing this delicious fruit in Canada, is larger than is commonly supposed. A few good specimens of the Nectarine were on Exhibition, but this fruit does not appear to be in general well adapted to the climate of Canada. Perhaps a better knowledge of its habits and more

careful attention to culture would render it more successful.

In vegetables the general display was very good, and comes up fully to former years. Cauliflowers were both large, and fine in quality. Cabbage not quite so large as in more favorable seasons. Tomatoes, Capsicums, onions and turnips were good, and shown by producers from various parts of the country. The show of squashes was extensive, some of the specimens being too large for table use. The celery was excellent.

The display of Green-house plants was, perhaps, superior to any former occasion, and attracted general attention. In Dahlias, the show of this favourite flower was not very fine, the season not being favorable. In Fuschias also the display was limited; the season being too far advanced to exhibit them in perfection.—There was an excellent assortment of Annuals in bloom, with quite a number of new varieties. Verbenas, beautiful and indispensable bedding out plants, were very fine and exceedingly well grown. The Bouquets were tasteful, the flowers artistically arranged, and the competition keen. It is to be regretted that no really good specimens of rustic ornamental work were shown, and we recommend some of our professional gardeners to try their taste and skill in this way, and produce a piece of work that would be both useful and ornamental to the garden.

#### ARTS AND MANUFACTURES.

The Exhibition Building was, as is usual on these occasions, filled to repletion with articles of the various kinds of manufactures, while the eastern galleries were mostly occupied with ladies' work, paintings, and musical instruments. The west wing comprised a large assortment of beautiful green-house plants, and a very splendid collection of fruit,—the apples, pears, plums, peaches and grapes added much to the variety and richness of the vast collection of varied articles which this capacious building contained. Throughout the Show the "Crystal Palace," as the Exhibition building is commonly termed, was the great centre of attraction to classes of people, and was thronged throughout.

In Sewing Machines much progress has of late been made, there being several different kinds on exhibition, manufactured in the Province. A very few years since everything of this kind was imported, Mr. Soper, of Woodstock, had an improved Singer Machine particularly adapted to heavy work. The price varies from \$75 to \$85, according to size. Mr. Soper has recently sent one of his machines to England. Mr. Halligan, of Newmarket, exhibited a machine possessing some novelties in construction, and it is said does

its work well:—one principal peculiarity is a double stitch for waxed thread. Messrs. Wanzer & Co., Hamilton, exhibited quite a number of machines of different constructions, the produce of their own well-known manufactory. Their combination family Sewing machine is well known and appreciated, simple in its construction, does not easily get out of order, and is easily worked. Messrs. Patterson & Irwin had some beautifully made Singer's machines, possessing some recent improvement of the shuttle. For this machine there is a constantly increasing demand.

Mr. Walton exhibited specimens of roofing Slate from Lower Canada, of excellent quality and color; the latter is said to be permanent. Some beautiful white marble mantle-pieces of superior design and workmanship were shown by Mr. Steiner, and Mr. W. H. Sheppard of Toronto; also a number of tomb stones in marble, having groups of well executed figures, by Mr. Armitage, and Messrs. Borrowman & Pearce, of the same place.

In Lamps and illuminating fluids there was an extensive and highly creditable display. Messrs. Parsons, of Toronto had a fine collection, consisting of rock oil, lubricating oil, and benzine, the latter being a product of petroleum, an article for which there is an increasing demand in England at improving prices. The newly formed refining company of Enniskillen had a number of specimens of crude petroleum and its various products. Mr. Hugh Miller, of Toronto, exhibited different specimens of oils, and an "Illuminator," which is said will burn without a chimney, and to consume products hitherto regarded as almost worthless. Mr. Esmonde showed a sample of lubricating oil, made entirely from petroleum, and sold at the extraordinary low price of 25 cents a gallon; and it is consequently getting into great demand. Mr. Pomeroy, of Toronto, had an extensive assortment of animal oils of superior quality. And H. Piper & Brother had a fine display of coal oil lamps, and several excellent specimens of workmanship in tin and copper.

The village of Gananoque, on the St. Lawrence, continues to increase in manufactures of iron and steel, as was evinced by its numerous productions at the Exhibition. Mr. Jones has heretofore been an extensive exhibitor in spades, shovels, hoes, forks, and such like articles, of very superior workmanship, the absence of which was felt as a loss on this occasion. Mr. Briggs had a quantity of handsome steel carriage springs, and an assortment or pumps. Messrs. Cowan and Britton showed numerous samples of nails of all kinds in common use, and a specimen of pressed nails, for which they obtained a patent. Messrs. Warner & Britton had some well made specimens of articles in tin, Britn

tannia Metal and Alberta spoons; and Mr. Bullock exhibited a coffee mill, and numerous other articles in metal. Mr. Hart had a complete assortment of files, and Mr. Robinson an excellent collection of scythes, axes and other edge tools. Mr. Brown's lock, (of Toronto) is a curious piece of workmanship, and apparently impracticable to pick.

In the important department of Harness the show was larger than usual, and the workmanship and quality of the articles generally betokened an increasing improvement. Mr. Stewart, of Toronto, an old and successful Exhibitor, had an extensive assortment both of heavy and light harness, saddles of various patterns, and ladies quilted Somersets. Mr. Hinder, of King Street, Exhibited good specimens of ladies' quilted and gentlemen's shafted saddles, as did Mr. Thompson, Mr. McGivern of Hamilton, all of excellent workmanship. Mr. R. Nicholls, of Toronto, exhibited various styles of horse collars, a department to which he devotes special attention. Mr. Porter, from Bowmanville, Mr. John Scott, of Caledon East, Mr. Jackson, of Peel, had also some specimens of harness, well made and adapted to the wants of the country. Mr. Clarke, of Toronto, showed a fine collection of trunks, valises, travelling bags, &c., which attracted much attention. Of boots and shoes there was a large display both from makers in Toronto, and various parts of the country, much of which indicated neatness, strength and skill. In leather the entries were numerous, and the specimens exhibited of the various kinds clearly indicated steady improvement in this important branch of domestic manufacture. Among the exhibitors may be mentioned Mr. McGlashan, of Toronto, Messrs. Pointer, of Churchville, Mr. Figgs and Mr. Bate, of Toronto Township, all of whom had specimens of various kinds of leather of first rate quality. Mr. Maclean, of Chippawa, and Messrs. Cook & Co., of Yorkville, also contributed liberally to this department.

Messrs. McCausland & Howard, of Toronto, made a very creditable display of Stained Glass; comprising specimens of English decorated of the fifteenth century, and others adapted to the dwellings of modern times. The specimens exhibited were generally meritorious both in design and execution.

Rice Lewis & Son exhibited some heavy belting with circular and other saws, of the value of \$3,000. They were manufactured by Messrs. Morland, Watson, & Co; the belting is also from Montreal, being manufactured by the British American Rubber Company.

Messrs. Irvine & Jones, of Uxbridge, showed some large steel Amalgam Bells, possessing strength and distinctness of tone; three hundred of these bells have been made and sold within the last 18 months. Mr. Bain, of Sand-

wich, had specimens of a cemetery fence and posts of cast-iron, his own invention and casting. A singular feature of this article is that the chain is cast in one piece. Price \$1 50 per foot of the fence, including the posts.

Messrs. J. & J. Taylor showed quite a number of thier well known Patent Fire and Burglar Proof Safes, of an improved style and excellent workmanship. These articles have for some years enjoyed a large share of public confidence and favor.

A large number of stoves of various patterns and uses were exhibited by Messrs. J. G. Beard & Sons, and Mr. J. McGee, both of Toronto. Great improvement has of late years been made in the manufacture of these articles, and large quantities are annually made in different parts of Canada.

Mr. D. S. Keith, Toronto, exhibited several articles of interest. His "Self-regulating, low pressure, steam warming apparatus," seems well adapted to private dwellings, as it requires comparatively little attention. Mr. Keith also exhibited Gas Works, for making gas from petroleum, wood, resin, &c.; the process is simple, and the apparatus but little liable to become deranged. His Green-house Boiler seems to be both economical and effective.

Mr. Bullock, of Toronto, showed some very good specimens of stained glass, including a figure of St. Peter, and a variety of interesting Gothic work, specially adapted to windows for churches; also some embossed white work for private dwellings, and a number of pen and ink figures for stained glass. This establishment has turned out some superior productions, both for domestic use and church ornamentation, the coloring of the glass being bright and permanent, and the designs generally correct and graceful.

#### CABINET-WARE.

In the furniture department this year, there was no competition. Messrs. Jacques & Hay walked the course unopposed, and carried off all the prizes for furniture offered by the Association. The articles they exhibited, even if there had been competition, would have been exceedingly hard to beat, being of a quality and finish equal, if not superior to any thing of the kind we have seen at any previous show. Their set of bedroom furniture, which obtained a first prize; was of polished black walnut, the material of which it was made, and the heavy carved work upon it, giving it a rich and massive appearance. The foot-board of the bedstead had as a centre-piece a view of the St. Lawrence and the Victoria Bridge very well carved. The head and foot-boards were veneered on both sides, and presented beautiful polished surfaces. The dressing glass stand was also a handsome piece of furniture. Each pedestal contained a set of

shelves of polished curly maple. The doors of the pedestals were polished inside and out. Behind the glass was some neatly executed fret-work. A black walnut wardrobe accompanied the set, but had awarded to it a separate first prize. It was lined inside with polished maple, the shelving being of the same material, which makes a very effective contrast with black walnut in articles of furniture of this kind. The trusses and cornices were elaborately carved. This wardrobe it was stated, has been sold for \$350, and is to be sent to England. Another set of bed-room furniture, shown by Messrs. Jacques & Hay, got a second prize. This was of a much cheaper style, made of white wood (a species of poplar), and comprised a bedstead, bureau, and glass, an enclosed marble-top washstand, an oval table, chairs, and a wardrobe—the value of the whole, including the wardrobe being \$110. The wardrobe also obtained a second prize. Like the other articles, it was of white wood, and imitation ebony beading and moulding. Messrs. J. & H. showed another bedroom set, got up as a sample of simplicity and cheapness. It was of white wood, and comprised a bedstead, dressing bureau, wash stand, table, and chairs, the price of the whole being \$21. Their set of drawing room furniture was very handsome. It comprised a sofa, a gentleman's easy chair, a lady's easy chair, a devotional and other chairs, and a centre table. The cushioned part of the sofa and chairs were covered with rich crimson and gold brocade, and the carving on the wood work was of the first style of excellence. A first prize was awarded for the drawing-room set, another for the sofa, and another for the centre table, which was of black walnut, neatly covered. The selling price of the centre table was said to be \$80. They showed also some dining-room chairs, covered like the drawing-room set with crimson and gold brocade. They also sent in, but at too late a period to be entered for a prize, a lady's dressing chair, an ottoman, and some other articles. They obtained the first prize for the best specimen of turned work, the article they exhibited being a lady's work table of bird eye maple. Specimens of turning sent in by Messrs. Smith & Burke, of this city, got the second prize. Among the goods exhibited by Messrs. Jacques & Hay, we observed also a handsome inlaid chess table, made of twelve different kinds of wood, walnut, curly maple, cherry, oak, basswood, &c. The white squares were of hickory, and the dark of walnut.

Messrs. Smith & Burke of this city, exhibited some capital specimens of joiner's work, and machine wrought moulding and flooring, for both of which they carried off first prizes.

Collections of veneers from Canadian woods were shown by W. Clements, Mewbury, C. F. Rose, Dawn Mills, and J. F. Purdy & Co., Newbury. Some very fine pieces were shown by Mr. Clements. They were all in an unpolished

state and comprised veneers of maple, birdeye oak, curly, and birdeye maple, &c. Mr. Clements got the first prize, and he also shared a portion of the honour of the prize for the best bed-room furniture, having supplied Messrs. Jacques & Hay with the veneers for it. The specimens shown by Mr. Rose were polished, and had awarded to them the second prize.

### FACTORY MADE WOOLLEN CLOTHS.

The show this year of woollen cloths of Canadian manufacture, exceeded in amount, in the number of competitors, and in the quality of the goods shown, what has been witnessed at any previous Provincial Exhibition.

The Port Dover Woollen Factory is added to the number of competitors this year. It commenced operations last spring. The Joint Stock Company formed to establish it put \$12,000 worth of machinery into the building, and then rented it to Mr. J. N. Pitts. Judging from the quality of the material shown, we would say they could not have placed it in better hands. Mr. Pitt constantly employs forty hands and turns out about 300 yards of goods per day. The tweeds shown at the fair by his agent, Mr. M. C. Nickerson, could not easily be surpassed, and other styles were also very good. Mr. Pitts obtained a first prize for the best piece of winter tweed shown; the second prize for summer tweeds; the second prize for fulled cloths; and a first prize for the best assortment of woollen cloths, tweeds, &c. The assortment comprised thirty-five pieces. It is exceedingly creditable to the Port Dover Company, that at the very first show at which they had an opportunity of competing they carried off so many honourable distinctions. Mr. Nickerson claims that the goods sold by this company at the same rate as English goods of a similar grade, are of 25 per cent. better quality; the English goods, he says, being to a greater or less extent filled in or backed with "shoddy," while the Canadian articles are entirely of the genuine wool.

The Ontario Woollen Mills of Cobourg (Messrs. Fraser & Co.) continue to maintain their well-earned reputation, and sent some very fine samples of their manufacture. Messrs. Fraser & Co. got a first prize for the best piece of broad cloth of Canadian manufacture; a first prize for the best piece of fulled cloth; and a second prize for winter tweeds. They showed also some capital factory-made shawls, which would no doubt have got a prize, had any been offered for that description of goods. The Ontario Mills continue to do a large business. They keep about 100 men constantly employed, and make from 800 to 900 yards of cloth per day.

W. Barber & Brothers, of Georgetown, make an excellent display in the same department. They got the first prize for summer tweeds; a second prize for mixed satinet; an extra prize

for doeskins; an extra prize for a sample of Oxford grey; and an extra prize for black cassimere from merino wool. The Messrs. Barber showed some very fine flannels. They got both the first and second prize for red flannels, and the first prize for white flannel. They employ constantly in their woollen factory from 80 to 100 men.

Disher & Haight, of St. Catharines, sent a good assortment of woollen cloths, flannels, &c. In satinets they had the pre-eminence over all competitors, receiving the first prize for black satinets, and the first prize for mixed satinets.

Messrs. B. & W. Rosamond, of the Victoria Woollen Mills, Almonte, showed some excellent samples, and were awarded the second of the prizes for the best assortments of woollen cloths, tweeds, &c.

Platt Hinman, of Grafton, was also an exhibitor in this department, and carried the second prize for broad cloths.

Ezekiel Snyder, Brockville, showed a variety of blankets, woollen carpets, &c., and obtained several prizes.

#### MISCELLANEOUS.

Messrs. Booth & Brother, of Yonge street, Toronto, showed the best assortments both of copper ware and tinsmiths' work, and obtained the first prize in each department. Their assortment included some handsome block tin ware, a style of goods never before manufactured in Canada.

Two very complete maps of Canada, Tremaine's and Tackabury's, which have been recently published, excited a good deal of interest, and the Judges awarded to each an extra prize. Messrs. Chewett & Co. exhibited several county maps, which they have lithographed, and their school map of British North America, prepared under the supervision of the Educational Department of Upper Canada.

Messrs. Barber & Bothers, of Streetsville, and Messrs. Buntin Brothers, of Toronto, were the only exhibitors of paper for printing, writing, &c. Very creditable samples were shown by both firms. The first prize was awarded to the Messrs. Barber, and the second to the Messrs. Buntin. The Messrs. Barber also sent specimens of their decorated and satin gilt paper hangings, which they manufacture of a superior quality.

We have already noticed the collection of native plants, for which a first prize was awarded to Dr. Poole of Norwood. A very full and carefully prepared botanical collection was also shown by Miss. Kate Crooks, of Hamilton, and obtained the second prize. A book of Canadian ferns and leaves, prepared by Mr. Dredge, Toronto, was commended by the Judges.

An extra prize was awarded to Mr. Thomas

Hill, Toronto, for his paper-cloth address labels. Being at once strong, flexible, and capable of being easily written upon, they seem to serve admirably the purpose for which they are designed.

John Cook, Toronto, showed some very pretty sheepskin mats, the wool of which was of silky fineness and very delicately tinted. He exhibited also an assortment of gloves and mits. Mr. Cook received an extra prize for his mats.

The show of furs was unusually scanty. There was no competition worth naming. The cap and gloves, and sleigh robe, for which Mr. Henry Ferdinand, of Waterloo, received first prizes, were of otter, and were fair enough specimens.

John Gartshere & Co., of Dundas, were large exhibitors, and received as they deserved, a considerable number of prizes. Among other articles which they showed were a 40 horse power engine, a locomotive driving-wheel, a locomotive casting, a centre discharge water-wheel, a treble suction smut machine, a pair of millstones, a patent bran duster, a locomotive boiler, and a grain separator.

Messrs. Miles Welsh, of Paris, and H. Augustine, of Orwell, exhibited one of Brickley's self-acting hand looms, patented in 1859. The loom shown had some new improvements, for which a fresh patent has just been asked. It works easily by turning a crank, and was kept frequently in motion during the show. An extra prize was awarded for it.

Some useful machines were sent from the Novelty Iron Works, Dundas, including their cracker and biscuit maker, their sugar crushing mill, and their improved grocer's coffee mill, for all of which prizes were awarded.

Messrs. Alcock, Laight & Co., of this city, exhibited a large and complete assortment of imported fish hooks, fishing tackle, needles, &c., which received one of the prizes given for foreign manufactures.

Messrs. J. G. Joseph & Co., Toronto, exhibited some most beautifully executed silversmiths work, for which they obtained the first prize. Their goldsmiths' work also, was very superior.

Mr. Thomas Herrick, of Toronto, exhibited an interesting collection of minerals from the neighbourhood of Fort William, on Lake Superior. They included some beautiful coloured crystals, of amethystic quartz, and a variety of specimens of iron, lead and copper ores. A first prize was awarded to Mr. Herrick's collection. The second prize for Canadian minerals was awarded to Mr. W. W. Fox, of Toronto, who showed a very good collection of copper ores from the eastern townships, iron ore from the St. Maurice, and other minerals.

Mr. Haughey showed a Roman Ionic capital and other specimens of Canadian marble, which excited a good deal of interest.

## Visit of His Excellency the Governor General.

On Wednesday afternoon, at 2 o'clock, His Excellency, accompanied by Lady Monck and family, Lord Mulgrave, Governor of Nova Scotia, Lady Mulgrave, with several gentlemen of his Excellency's suite, and the officers of the Association, assembled on a platform erected for the purpose at the east end of the Mechanics' Hall. The Vice Royal party were enthusiastically cheered as they entered the grounds, the Cobourg Band playing in excellent style the National Anthem, when after the cheers had subsided, F. W. Stone, Esq., the President of the Association, read the following Address and presented it to his Excellency:—

TO HIS EXCELLENCY THE RIGHT HONOURABLE  
CHARLES STANLEY VISCOUNT MONCK, GOVERNOR GENERAL OF BRITISH NORTH AMERICA,  
&c., &c., &c.

MAY IT PLEASE YOUR EXCELLENCY:—We the Farmers, Manufacturers, and Artisans, constituting the Agricultural Association of Upper Canada, beg to tender to your Excellency a cordial welcome to the display of the results of our industry on this occasion of our Annual Exhibition, and of your Excellency's first visit to Western Canada.

A beneficent Providence has blessed our labors with a larger increase than could have been anticipated at an earlier period. The season, in some respects, has not been favorable to the pursuits of the Husbandman; still we trust that your Excellency in visiting the various Departments of the Exhibition, will be enabled to form a correct estimate of the industrial condition, social welfare, and great capabilities of this rapidly improving Province.

From the interest which your Excellency is known to have taken in promoting these important pursuits in the Mother Country, we fondly hope that they will continue to receive here your Excellency's fostering care, and that Canada, during your Excellency's administration, will continue to advance in all that is necessary to the growth and prosperity of a free, united, and happy people.

While we deeply deplore the civil strife that is now raging in the great adjoining Republic, and continue to feel the strongest desire to maintain friendly relations, and a generous rivalry in those pursuits which tend to civilise and bless mankind, yet, should our peaceful shores unhappily become threatened with invasion, we shall not, we trust, be found wanting as a united and loyal people in bearing our portion of the burthens and dangers incidental to a vigorous defence.

We trust that your Excellency, Lady Monck and family, will enjoy your visit to this section of the Province, and that the evidences which your Excellency cannot fail to witness of its

material prosperity, social contentment, and genuine British feeling, will unmistakably indicate an unswerving fidelity to the Crown, and the integrity of the Empire.

## HIS EXCELLENCY'S REPLY.

TO THE AGRICULTURAL ASSOCIATION OF UPPER CANADA.

GENTLEMEN,

I heartily acknowledge your kindness in welcoming me, as you have done, to Toronto.

I rejoice with you at the favourable result of the present harvest, and I look forward with much interest to the opportunity that will be afforded me of closely inspecting the contents of the Exhibition.

I observe with pleasure that farmers, manufacturers, and Artisans are all joined together in your Association. The interests of these several branches of industry have often been represented as different, but you, Gentlemen, know that such is not the case, and that the prosperity of each contributes to the well-being of all.

This part of the Province is pre-eminently adapted for agriculture. The wheat grown here is some of the finest in the world, and I was much struck with the well cultivated and clean looking farms in every part of the country between this and London. I also saw a considerable quantity of well-bred stock, and excellent horses. On the whole I am much pleased with what I have noticed of the farming in Western Canada, and having, as you have observed with truth, been something of a practical farmer myself, I think that perhaps you may be glad to hear the favourable opinion I have formed of it.

Toronto, Sept. 24th, 1862.

Several hearty cheers were given by the large concourse of people surrounding the stand, after which the Vice Royal party, accompanied by the Officers of the Association, proceeded to view the various departments of the Exhibition.

## THE DINNER.

The dinner to His Excellency was given in the afternoon of Wednesday, in a tent erected in the beautiful grounds of the Lunatic Asylum. Upwards of 500 gentlemen were present at the entertainment. His Excellency arrived from the Exhibition grounds shortly before three o'clock. When he entered the tent, accompanied by His Worship the Mayor, the President of the Agricultural Association, and other gentlemen, he was received with enthusiastic and prolonged cheering. His Excellency and other distinguished guests sat at a cross table on an elevated dais erected at the north side of the tent, and the rest of the company at four long tables stretching from it.

His Worship, Mayor Bowes, occupied the chair, having on his right the Governor General,

Lord Monck; Hon. J. S. McDonald, Attorney General West; — Atkin, Esq.; Col. Gordon, of the 17th Regt.; Hon. G. Alexander, M.L.C.; Hon. T. D. McGee; Col. R. L. Denison; Capt. Retallack; Chief Justice McLean; Chief Justice Draper, and Chancellor Vankoughnet. On his left were Earl Mulgrave, Lieutenant Governor of Nova Scotia; Major General Lord Frederick Paulet; Hon. Mr. Wingfield, of the Life Guards; F. W. Stone, President of the Agricultural Association; Major General Napier; Rev. Dr. McCaul; Col. E. W. Thomson; Col. Irvine; Hon. David Christie, M.L.C.; Denis Godley, Esq., Col. G. T. Denison; Hon. M. H. Foley; Hon. John Ross, and Hon. J. B. Robinson.

There were also present among the general company, Hon. W. H. Howland, M.P.P.; Hon. Wm. McDougall, M.P.P.; Hon. O. Mowat, M.P.P.; Hon. G. W. Allan, M.L.C.; Hon. J. H. Cameron, M.P.P.; Angus Morrison, M.P.P.; H. Munro, M.P.P.; W. Patrick, M.P.P.; A. McKellar, M.P.P.; T. M. Daly, M.P.P.; John Crawford, M.P.P.; Dr. Connor, M.P.P.; Amos Wright, M.P.P.; T. C. Street, M.P.P.; M. C. Cameron, M.P.P.; Hon. Henry Ruttan, Hon. W. Cayley, Hon. Robert Spence, Bishop Strachan, Rev. S. Givens, Dr. Workman, Dr. Reid, of the 30th Regt., Alexander Manning, G. P. Ridout, Lewis Moffatt, W. Ferguson, Ex-President of the Agricultural Association, Recorder Duggan, Rev. Dr. Barclay, Dr. Small, Rev. Dr. Ryerson, G. A. Barber, S. Fleming, Rev. Mr. Marling, W. H. Boulton, Hugh Miller, Professor Hirschfelder, Professor Hind, Dr. Agnew, Coroner Duggan, T. Hodgins, J. G. Hodgins, Thomas Reynolds, F. W. Cumberland, Dr. Beattie, of Cobourg, George Boomer, Police Magistrate, David Buchan, R. A. Harrison, Rev. Dr. Green, Rev. Mr. Williams, of the 30th Regt., Dr. King, of Columbia College, New York, O. R. Gowan, James Cotton, F. C. Capreol, W. Clay, Major Gray, of Hamilton, T. D. Harris, J. D. Ridout, John Duggan, S. Phillips Day, of the London (England) *Morning Herald*, J. S. Denis, H. Rowsell, Aldermen Sterling, Jarvis, Carr, Hynes, Sproat, Brunel, Dunn, Godson; Councilmen Edwards, Love, Boxall, T. Smith, Spottiswood, Bell, Higgins, Reid, &c. &c.

The celebrated Cobourg Brass Band was in attendance in a small tent behind the Mayor's table, and supplied some excellent music as the toasts were successively given.

The Mayor said it was unnecessary for him to preface the first toast with any remarks. He begged to propose—"The Queen—God bless her."

The Toast was drunk with all the usual manifestations of loyal enthusiasm.

The Mayor next gave the "Prince of Wales and the rest of the Royal Family." (Cheers.)

The Mayor then said—My lords and gentlemen, I come now to the principal toast on this occasion, one which I know will be happily responded to by every one present. (Cheers.)

The representative of Royalty now with us is a link binding us with Great Britain, and I trust we shall long continue to have in Canada a representative of the British Crown. But we can boast of a still stronger tie in that loyalty which has ever characterized the Canadian people—(Cheers)—a loyalty fostered and deepened by the liberty which we enjoy. This country has prospered under British rule. I need only point to the Exhibition now being held in this city, as sufficient to prove to his Excellency the progress this country is making in agriculture and manufactures. We have had a temporary injury—I hope it is only temporary—done to our trade and commerce by the troubles now occurring in the United States,—troubles in which we have taken no part, but which have exerted upon us an important influence. I trust it is the desire of every gentleman present, and the prayer of every Canadian, that these troubles may be speedily and satisfactorily settled—(cheers)—and that the good feeling which now happily exists between this country and the United States may ever continue. (Cheers.) I see nothing at present likely to disturb that good feeling, but should Great Britain, for the maintenance of her national honour, be ever forced to go to war with the United States, I trust, and I am sure I may say it with confidence, that there will not be a disloyal man in Canada. (Cheers.) I am quite sure that there is no foundation whatever for the idea which has got abroad in England, and which has even found expression in the British Parliament, that the people of this country would desire that Great Britain should fight her battles alone on this continent. Cries of No! No!) I am confident that I speak the sentiments of every one present, and of every man in Canada, when I say that we will be ready to make every possible sacrifice, both of men and money, to maintain in this country British honour and British connection. (Cheers.) to have at their head a nobleman, who, as your lordship does, possesses the confidence of the whole people of this country. (Cheers.) I give you the health of Lord Monck, the Governor General of the Provinces.

His Excellency's health was drunk with great enthusiasm, the cheers being given right lustily, and being again and again repeated.

His Excellency, on rising, was greeted with renewed cheers. He said,—Mr. Mayor and gentlemen, I thank you most heartily and unaffectedly, not only for the reception which my name has met amongst you, but for your having given me this opportunity of meeting with the bone and sinew of Western Canada. (Cheers.) I can scarcely conceive any meeting more interesting than that between the representative of the Sovereign of this great Empire, and the men who have conquered so magnificent a tract from nature to add to her dominions. (Cheers.) I have also to congratulate myself on the circum-

stance that my visit has been made at the time of your Provincial Exhibition. I have gone through that Exhibition with great care to-day, and I may say with some little knowledge of the articles exhibited, for at home I am myself a practical farmer. (Cheers.) And I say it, gentlemen, not in any way with the view of flattering you, but I say it as the simple truth, which has commended itself also to the judgment of some of my friends about me, who have witnessed the exhibitions of the Royal Society of England, that if your exhibition on these grounds to-day were laid alongside of theirs, there would be very little to choose between them. (Cheers.) I cannot but think that this is a subject of congratulation for this portion of the Province of Canada. Your country now, and for years to come, must be mainly an agricultural country, and you cannot over-estimate the importance or the value to you of bringing here so good stock to start with in the race of farming competition. (Hear, hear.) I have, within the last few months, had an opportunity of traversing the greater part of this Province, certainly in rather a hasty and desultory manner, but I have everywhere been met by exhibitions and demonstrations of loyalty to the throne, and of personal kindness to myself, culminating in this magnificent demonstration at Toronto. And I cannot help feeling the deepest gratitude on personal grounds, and the greatest satisfaction on public grounds, at the way in which I have been received. (Cheers.) Gentlemen, this is not the compelled adulation of a servile population to the satrap of a despotic monarch; it is the unpurchaseable, spontaneous, and reasonable outpouring on the part of a free people of their sentiments of affection to their sovereign, their attachment to the throne, and their stern determination to maintain unbroken the unity of her glorious empire. (Great cheering.) I never entertained a doubt of the loyal feelings of the people of Canada—(hear, hear,)—and I believe that, if the occasion should unfortunately arise for the practical exhibition of those feelings, not a man in Canada would be wanting in his place, when that occasion arose. (Cheers.) Gentlemen, I am in a position to state to you, that not only I myself, but those who are responsible to the people of this country for the government of the country, have at heart the question of preparation for national defence as strongly as have any men at home. I trust that in a few days a system will be promulgated to you, which will enable the people of this country, in a manner inexpensive to themselves, and little onerous in regard to their industrial avocations, to put themselves in such a position of self-defence as will ensure them against aggressive attack. (Cheers.) I beg to thank you for the kindness with which I have been uniformly received in my progress through Canada, and I beg not only to thank you but to congratulate you on the loyal feelings by which you are animated.

I trust that I may be enabled, during the period it shall please my Sovereign to allow me to remain in my present position, to exert some influence in developing the resources of your country; and I trust that I may hand you over to whoever succeeds me in position, largely improved in material progress, and with your loyalty and affection to the British Empire un tarnished and undiminished. (Great cheering.)

The Mayor said—The next toast on my list requires very little introduction from me, but I claim for it as warm and hearty a response as has been given to those that have preceded it. From the effect produced by the troubles in the United States on the trade and commerce of Canada, we are led to infer the advantage to a country from being in friendly connection with those adjoining it, not only when those countries are governed by the same laws and subject to the same sovereign, glorying in the liberty which is the heritage of British subjects, but even when they are not governed by the same laws. Even in that case, when contiguous, they exercise an important influence, one upon another, and the results are most unfortunate when any difficulty arises between them. The sister provinces are separated from us by ice-bound waters for half the year; yet we acknowledge the ties by which we are bound. We glory indeed to acknowledge those ties, and I would wish to say to Lord Mulgrave, whose health I am about to propose, that we offer him a cordial and hearty welcome to Upper Canada. (Cheers.) And I may say—although I am not going to give an opinion upon the subject now under discussion, that of the Intercolonial Railroad—that I trust, if it is carried out by the gentlemen who have it in charge, that it will connect with us commercially the maritime Provinces, and ultimately lead, I hope, to the extension of communications with the Northwest Territory, pouring into the lap of Canada the trade of that region which is now diverted to fill the coffers of a foreign country. It was said on one occasion by Lord Elgin, in connection with this Intercolonial Railroad scheme, that the citizens of Toronto, in a very few years, would be able to breakfast on fresh fish from the Atlantic and Pacific. I trust the time is fast approaching when that prediction will be accomplished. (Laughter and cheers.)

Earl Mulgrave, who, on rising, was greeted with renewed cheering, said—Mr. Mayor, Lord Monck, and gentlemen, I take the manner in which you have responded to the toast which you have just drunk, as an earnest of the brotherly affection and regard which exist between Canada and the Lower Provinces. (Cheers.) This regard, and this affection, I can assure you are fully reciprocated by the Province over which I have the honour to preside. (Cheers.) Unfortunately at the present moment we are separated by distance and difficulty of communication, preventing that cordial and easy inter-

communication between the colonies, which is so desirable for all of us. This distance and this difficulty of communication, I trust most sincerely, may soon be overcome. Once united by an iron band, we shall be able to communicate with one another, and to interchange our articles of commerce, and nothing I believe is more likely to add to the happiness, advancement, and prosperity of all her Majesty's dominions on this side of the Atlantic, than our being thoroughly united and in easy communication with one another. In this Province you have many advantages which we do not possess in the Lower Provinces. You have a climate as good as any, I believe, in the world. You have a soil rich, fertile, and almost virgin. You have conquered the soil from the wilderness in a manner which does infinite credit to the hardy sons of Canada. And I trust that, when the communications are made intimate between us, the Lower Provinces may learn many things from Canada. And I trust that Canada may learn something also from the Lower Provinces. (Cheers.) We have our advantages as well as you have yours. We have a mineral wealth in Nova Scotia which I believe is almost unequalled in the world. Coal we have in abundance, and within the last 18 months we have found the precious metal which all so anxiously seek after. (Hear, hear.) This discovery has not, as yet, been fully developed, but I doubt not, that ultimately Nova Scotia will become a gold producing Province. That this will add to her wealth and prosperity no one can doubt, and I trust that whatever prosperity she may enjoy, Canada, by a closer connection with her, may be enabled to participate in that prosperity. (Cheers.)

The Mayor said—The next toast is "The Army and Navy." (Cheers.) It is almost unnecessary for me to preface this toast by a single remark. The bravery of the British Army on many a well-fought battle-field is known to every one present. The gallantry of the navy is quite equal to that of the army, and it would be useless for me to add another word in recommendation of the toast I now give you—"The Army and Navy of Great Britain." (Cheers.)

Major General Napier, on rising to respond, was warmly cheered. He said—Mr. Mayor, my Lords and gentlemen, I assure you that I have great pleasure in rising in the name of the army to return thanks for the very kind way in which you, Mr. Mayor, have proposed our health, and the very flattering manner in which you, gentlemen, have responded to it. We soldiers always appreciate, and are always glad to receive the approbation of our fellow-citizens. (Cheers.) It would ill become me as a soldier to say much of the army. I think I may safely leave their deeds to speak for themselves, but this I can say, and this I will say, that whenever, and wherever the services of the British army may be required, I feel

sure that you will find we shall do our duty. (Cheers.) I wish also to take this opportunity of expressing my admiration of the way the volunteers of Toronto have turned out. I know—and no one knows it better—the difficulty the volunteers have in getting drill, and I must say that I was very much astonished at the perfect manner in which they went through the *manœuvres* yesterday.—(Cheers.) And I trust, from what has dropped this afternoon from the Governor General, that the very next time I have the honor of having the volunteers under my command, I shall have as many thousands as I had hundreds yesterday. (Cheers.)

Capt. Rubidge, R. N., of Peterboro', C. W., returned thanks on behalf of the British navy, and remarked that, whenever their services were required, their motto was "Ready, aye ready." (Cheers.)

Lord Monck again rose and said—With the permission of our Chairman, I beg to propose a toast. As the subject of that toast is much better known to every one of you than he is to me, I conceive it would be impertinence on my part to intrude upon you any observations in reference to it. I beg to give you the health of our worthy chairman, the Mayor of Toronto. (Loud cheers.)

The Mayor said—I deeply feel the unexpected honour done me by the Governor General in proposing my health, and the very cordial manner in which it has been received by this very influential assemblage, representing as it does every interest of this great country. I am sensible of my inability to do justice to the city I have the honour of representing here, a city that in all circumstances, even the most trying, has always proved her loyalty to the Queen and to the constitution. (Cheers.) The city of Toronto like other Municipalities, has suffered in trade, and in the reduction in the value of property, caused in a great measure by the alienation of the provincial credit and capital to the construction of public works in the country, works rendered necessary by the withdrawal from Canada of the protection she enjoyed from Great Britain up to 1846. In that year, the British Parliament, in the interest of the working classes of Great Britain, adopted a policy which compelled Upper Canada to compete in the English markets with the wheat-growing countries of the world. We could have no fault to find with this, but the Legislature and the people of this country were obliged, on account of the free trade policy of Great Britain, to pledge the credit and the capital of the country for the construction of railways to give to the farmers of Upper Canada easy and cheap access to the British market. The municipalities of the country, seconding the Government of the country, pledged their credit also for the construction of those railways. The city of Toronto went largely into the encouragement

of railways, in order to open up this country, and to bring to the door of every farmer a suitable market. Toronto also expended a large amount of money in order to give the Grand Trunk Railway an opportunity of uniting its Western and Eastern section opposite the city. Some of the politicians of the country—and I may be permitted to make this remark, although politics are excluded on the present occasion—some of the politicians of the country have considered that the country has gone too far in pledging its credit for so large an amount for some twenty or thirty years in advance. However, no one who contemplates the vast forests of this country, the immense extent of its mineral wealth and its great agricultural resources, can doubt that when we get enough hardy immigrants to develop our various resources, those railroads will before many years become not only a profit to Canada, but a profit to the proprietors. (Hear, hear, and some indications of incredulity.) This investment of our capital, and this pledging of the credit of the country, has brought about a consequent increase of the tariff. Our English friends object to this, and very justly. But very probably we will come to consider before long the propriety of abolishing custom-houses altogether, and thus meeting the views of the manufacturers of England, and standing on more friendly terms with the people than heretofore. (Cheers.) And as our American friends are now coming as individuals to settle among us, probably the whole Northern States, and perhaps the whole Southern States, will by and by be wishing to join Canada, and coming to prefer the good old English strains, will substitute "God save the Queen" for "Hail Columbia." [Cheers and laughter.] And I have no doubt the people of Canada will join me in offering them a "cead mille Failte." [Cheers.] I again thank you for the manner in which you have received the toast of my health, which his Excellency has done me the honour to propose. [Cheers.]

Earl Mulgrave again rose and said—Since I arrived on the ground this afternoon, I have been requested to propose a toast to you, and most willingly do I do so, though I regret that the task has not fallen to one who, by a more intimate knowledge of your country and greater eloquence, would be able to do greater justice to it. Having in former days resided for some years among you, I was vain enough to suppose that I knew something of Canada. My present visit has taught me how little I really knew of her. I have been in the habit of admiring and frequently praising Canada, but I had no idea till I arrived here a month ago, and had the opportunity of observing it myself, of the rapid stride you have made in the last twenty years. [Cheers.] Whether I look at the extent of your commerce, at your public buildings, or at your improvement in

agriculture, I am lost in amazement. And I must own that I have seen since I have been in your city, what has astonished me more than anything else. I had no conception that Canada could boast of Public buildings like those which I have seen in this city. (Cheers.) I yesterday had the pleasure of visiting the University of Upper Canada, and I assure you that I cannot call to mind at the present moment any modern building of the kind in England or elsewhere, with which that building would not favourably compare. (Cheers.) I have this morning had the opportunity of visiting your Osgood Hall, and that also is worthy of comparison with any buildings of the old country. This afternoon I have had the opportunity of witnessing the wonderful strides which you have made in agriculture. I have always myself taken a deep interest in agricultural pursuits, because I feel that without a due development of the agricultural resources of a country, whatever her commercial or her mineral resources may be, she cannot arrive at that position to which it ought to be the aim of every country to arrive. We may live without luxuries, we may live without the minerals, but cannot live without the food which is required to sustain us. I have frequently visited the agricultural meetings in England, and I can assure you that I do not think I ever witnessed a show, which taken as a whole, showed a larger number of specimens of what scientific agriculture can produce. (Cheers.) I do not mean to say that in some of the agricultural meetings in England you would not see individual animals which would compare with or even beat those which I have seen to day—I wish to be frank and I do not wish to flatter—but I will say that, taken as a whole, I never saw a more creditable display. (Cheers.) I believe there is nothing more calculated to improve your agriculture and your manufactures than those annual displays which you have so wisely instituted. Long may they continue and amply may you reap from them the rewards which you deserve. (Cheers.) As regards your commercial interests, I, a stranger among you, cannot speak so fully, because they do not so easily meet the eye. I had expected to see improvements in Canada. I knew that in a great and a new country, having a population such as Canada\* is blessed with, improvements must be rapid. You have not only the advantage of a soil equal to any in the world, but you have a climate which enables you to produce almost anything that you desire, and you have also the advantage in this new country of reaping the experience of the old. You have wisely availed yourselves of that experience, and the result cannot fail to answer the most sanguine hopes of those who are anxious for the prosperity of this country. Gentlemen, I propose to you, the agricultural, commercial, and manufacturing interests of Canada, and in connection with the toast, the

health of the President of the Agricultural Association of Upper Canada. (Cheers.)

F. W. Stone, Esq., President of the Agricultural Association, briefly responded. He thanked those assembled for the honour they had done him in drinking his health. He said he had been delighted with the Exhibition now in progress, and hoped to see the country continue to make progress in agriculture from year to year. He regretted that he had no experience as a public speaker, so as to be able to do justice to the interests of agriculture on this important occasion, and he would, therefore, call upon Col. Thomson, the President of the Board of Agriculture, who had been connected with the Agricultural Association since its commencement, to take his place in replying further to the toast. (Cheers.)

Col. E. W. THOMSON said they were now holding the seventeenth exhibition of the Agricultural Association of Upper Canada. Many within the sound of his voice would recollect when the Association held their first exhibition in this city, what a poor appearance they made at that time, and how many prophecies were indulged in that the project would not succeed. They were told that this was too young a country to undertake anything so gigantic. They did attempt it, however. How they had succeeded, it did not become him to say. He thought, however, if he were to refer to statistics, that he could show that their progress had been great. Since the first exhibition was held, they had advanced more than tenfold. (Cheers.) He had been called upon to respond to the toast, because he was one of the first instigators of the Exhibition. He and half a dozen other individuals took it into their heads that if an exhibition of this kind could be held in the State of New York, it could be held here also. They did not hope to equal the New York Exhibition, but they thought they might make the attempt, and gradually progress towards what they had witnessed on the other side. And now they had it acknowledged by all who had witnessed both, that the Exhibitions in Canada quite equalled those in the State of New York. (Cheers.) He would not draw a comparison between the Exhibition he witnessed this year at Battersea in England and our own. But he would say this, that when we took into account that the population of London alone was equal almost to the whole population of British North America, we had no reason to hide our heads. Our Exhibition on this occasion, if not equal, was not far inferior to the Great Exhibition of the Royal Agricultural Society of England. (Cheers.) In many departments we were quite equal, and in some, particularly in horses, we have a better exhibition here than they had at the Royal Agricultural show at Battersea. This arose from the fact that we had taken great pains to improve the breed of our horses, and that our spirited importers had brought from the old

country the very best they could find. As regarded both horses and cattle, the Association had encouraged their importation by giving a large additional premium, whenever a superior animal was brought in. Mr. Stone, Mr. Miller, Mr. Snell, and other gentlemen had turned their attention to the importation and improvement of stock, and had conferred, by their enterprise in that way, immense benefit on the country. (Cheers.) We had still, however, much improvement to make, in the department of implements. We had certainly improved very much on the implements shown at our first Exhibitions. These were brought over by manufacturers from New York State to show us how much better off the people there were than ourselves in that respect. But our mechanics studied those implements, copied them, imported largely the implements manufactured in England, and had now, he believed, exhibited for several years as fine a show of implements in Canada as ever were exhibited in any part of America. (Cheers.) But there still remained for our mechanical friends something to do. In visiting England, he had witnessed vast improvements in agricultural implements, and had seen a display in that respect far beyond what we could show here. In thrashing machines important improvements had been made within the last two or three years, which he hoped our ingenious mechanics would soon copy. He had been struck also by the portable steam engines for carrying on ordinary farm work, which all over America was done by horse power. He hoped that before long these improvements would be introduced into Canada, and that our motto would still be Onward! (Cheers.)

Rev. Dr. McCaul was requested by the Mayor to propose the next toast. He said he had much pleasure in proposing the health of those who had honored us with their presence on this occasion—of those noblemen and gentlemen who had come from that far off land, still endeared to us by the familiar name of home, long as we have lived here—(cheers)—of those too who had come from different parts of Canada, and were now around this board, representing the intelligence, the enterprise, and the industry which had made Canada what it is, qualities which he hoped would be transmitted by us to our descendants, who would reclaim those parts of the country not yet brought under cultivation, until the whole land should blossom even as the rose. (Cheers.) Most deeply did we value the honour conferred upon us by the guest of the day, his Excellency the Governor General, on this occasion. That nobleman had come amongst us with the reputation of many excellent qualities to recommend him. He had come here with great practical experience, such as would enable him to grapple with the political difficulties which might present themselves in the high position in which he was placed. He had come to us with a reputation for busi-

ness habits which we Canadians knew well how to value. And above all, he had come to us with the determination, as had been proven by the experience of it at home, to do his duty to the Queen and to Canada, with fearlessness, with honesty, and with impartiality. (Cheers.) Coming amongst us with such advantages, he thought he might predict that in the administration of the Government, his Excellency would exhibit those qualities which are pithily expressed in the motto of the noble house of which he is now the head, and that if danger should arise he will discharge his duty *fortiter*, with courage; that in every relation of life he will discharge his duty *fideliter*, with honor; and the result of such a discharge of duty must be *feliciter*, with a happy issue. (Cheers.) But there were other guests here this evening to whom he would desire to refer. Some of our friends from the other side of the lakes had done us the honour to come here. (Cheers.) He thought that, as a Canadian, he might assure them, that we extended the hand of friendship most cordially to every one of them. (Cheers.) Be they from the North or from the South, we knew no difference here. But we could assure them that amid the trouble and afflictions they were now enduring, they had the deepest sympathy of every reasoning man in Canada, and that our earnest prayer to the Almighty was, that he might speedily relieve them from this war, which was depopulating their cities, devastating their homes, ravaging their fields, and scattering their substance to the winds, and that He would speedily bless them with peace, enabling them to enter once more on that career of unexampled prosperity which they had previously enjoyed. (Cheers.) Dr. McCaul concluded by proposing "Our Guests." (Cheers.)

LORD F. PAULET said he had been requested to respond to this toast. After the eloquent speeches to which they had listened, it would be idle in him to attempt to make another. He would only say that some twenty-two years ago, when he first had the pleasure of visiting this city, there were no railroads, and he saw little or nothing of the Province of Upper Canada. He was happy now, on his return after a lapse of twenty-two years, to see the country so prosperous, and inhabited by a free and independent population. (Cheers.) He wished God-speed to them all. (Loud Cheers.)

DR. KING, President of Columbia College, N. Y., was also called upon to respond. He said he was entirely taken by surprise when his name was mentioned, as he was here in no sense as a representative person. He would say, however, that what he had seen had gratified him inexpressibly, and that the kind expressions which had been uttered on this occasion with regard to his country had touched him deeply. (Cheers.) We are in a state, he said, of great tribulation, but we of

the North believe that, in the spirit of the inheritance which we derive from the mother country, we are contending for the noblest principles of liberty. We insist that we are contending for that, for which Great Britain has been willing to sacrifice everything she possesses rather than surrender it, the power of the constitution. (Hear, hear.) We insist that, when we are told that certain claims cannot be admitted, and if pressed by the Federal Government should be resisted by arms, we would be unworthy of our descent if we did not say, take then the penalty of arms, we fight for all you have consented to be governed by, and if you say you will not be governed by this, we say you shall be, or we shall sink with our flag. (Cheers.) Dr. King then expressed the satisfaction he had experienced in visiting the public buildings of Toronto, and said that two such buildings as the University and Osgoode Hall were not to be found in the wide domain of the United States. He expressed also his satisfaction with what he had witnessed in the Exhibition. It had astonished him to see in this young country a display of such animals, of such products of the earth, and of such mechanical contrivances as were brought together on these grounds. (Cheers.) He was proud to feel that in the United States and Canada they derived their blood from the same source, and he trusted the day would never come when that blood would seek to try which of the two was the best, on the different sides of the lakes. (Cheers.)

HON. G. W. ALLAN was called upon by the Mayor to propose "the Exhibitors." He said it was to the exhibitors we were indebted for what we had witnessed to-day, and it was fitting that their health should be drunk on this occasion. He had listened with pleasure to the testimony borne to the excellence of this Exhibition by those who had an opportunity of witnessing the exhibitions in England, and he was happy to bear his own humble testimony to the same effect, having had an opportunity of seeing various English Agricultural Shows. It had been a matter of great pride and satisfaction to him to-day to compare the stock sent by Canadian exhibitors with what he had seen on similar occasions in England. (Cheers.)

COL. R. L. DENISON briefly responded.

HON. T. D. MCGEE was requested by the Mayor to propose "The Press." He did so in a few eloquent remarks, in which he spoke of the power of the press for good, if rightly used, and for evil if unscrupulously employed, and pointed out the beneficial influence it might exercise in this country, in removing asperities, rooting out prejudices, and training people coming from different countries with different feelings and habits of thought, to

live together harmoniously and amicably. Mr. McGee was warmly cheered throughout his remarks.

Hon. W. MACDOUGALL was requested, as having been connected with the agricultural press, to respond. He did so briefly.

Three cheers were then given for the Governor General and Lady Monck, three cheers for Lord Mulgrave, three cheers for the Queen, and the proceedings terminated about half-past five.

#### MEETINGS IN THE AGRICULTURAL HALL.

On Wednesday evening the first meeting was held in the spacious Hall of the new building of the Board of Agriculture, at the corner of Queen and Yonge streets, when the President of the Board took the chair, and gave a sort of historical sketch of the rise and progress of the Agricultural Association, tracing its gradual, and of late, rapid progress, in an interesting manner. He stated that in this new building the Board had got at length a habitation of its own, where every accommodation for offices library and museum was possessed at a comparatively small expense, the ground floor and basement having been leased to James Fleming and Co., as a seed and implement warehouse. The Board would now have permanent quarters, thereby avoiding the numerous and serious inconveniences hitherto experienced in changing their office, and will have to look to agriculturists and mechanics in different sections of the Province to assist them in furnishing the projected Museum with suitable and characteristic specimens. Some remarks were afterwards made by Professor Buckland, F. W. Stone, Esq. President of the Association; Asa A. Burnham, Esq., Hon. H. Ruttan, and Mr. Comstock, of the *New York Argus*, who spoke in complimentary terms of the Exhibition, and what he had seen of the spirit of Canadian farmers and mechanics. The meeting was but thinly attended, and adjourned to next evening (Thursday) to hear a lecture by Mr. Smith, Veterinary Surgeon to the Board of Agriculture, when F. W. Stone, Esq., took the chair at eight o'clock; the attendance was more numerous than on the preceding evening, but far from being so large as it ought to have been on such an occasion.

Mr. Smith delivered a practical and interesting lecture on the diseases of the horse, and their

proper modes of treatment confining himself chiefly to the diseases which he had found to be most prevalent among horses in this country. He illustrated his remarks as he proceeded, by referring to a skeleton of a horse placed on the platform. Spavin was the first disease he adverted to. Of this he said there were two kinds, the first arising from inflammation of the periosteum, and the second from inflammation of the internal structure of the hough. The former generally had its origin in some mechanical injury, and if it occurred well back and in a well formed limb, it generally did not interfere much with the usefulness of the animal; but, if it existed forward, it was well to have as little as possible to do with an animal labouring under such a disease. He explained how the existence of spavin might be detected, and then mentioned the best modes of treatment. In the early stage the application of cold water was a simple and effectual remedy. In the later stages, he recommended blistering or the insertion of a seton; and while under treatment, it was essential that the horse should have some six weeks or two months' rest. In the second form of spavin, where caries existed in the joint, the best mode of treatment was counter irritation. Mr. Smith made some remarks on bog spavin and blood spavin, and then passed on to the disease known under the name of windgalls. Most horses that had any large amount of work to do, had windgalls more or less, and their existence, if the qualities of the animal were generally good, should not lessen his value much, unless when they serve to indicate the existence of some other disease. In an early stage they could be removed, but if allowed to become confirmed they could hardly ever be got rid of. The mode of treatment he recommended was to allow perfect rest, and to bandage the parts affected with cold water bandages. He then proceeded to speak of diseases of the foot, the anatomy of which he minutely explained. One of these known by the name of navicular disease, he said he had found to be pretty common in Toronto. It arose from a strain of some of the fibres of the tendon passing over the navicular bone, the result being what was called a contracted foot. He mentioned the proper modes of treatment for the disease, the great thing being to attend to the shoeing, so that the toe should be as short as possible and the heel raised high, less pressure in this way being thrown on the tendon. He then referred to the treatment of corns, and proceeded next to speak of diseases of the lungs, especially heaves or thick wind or broken wind. Thick wind arose from a thickened, corrugated condition of the air cells, and frequently arose from colds or attacks of bronchitis not being properly attended to. The inspiration and expiration were quick; the capacity of the air cells being diminished, it was necessary for the air to be taken in very

frequently. Thick wind might be alleviated and in some cases cured. The great thing was to attend to the food; the animal should be fed on easily digestible and nutritive food. Broken wind, or what was called confirmed heaves, was caused by rupture of the air cells, so that the air escaped into the cellular tissue. In breathing, the expiration was done with a double jerk, and the disease was generally accompanied by a hollow cough. The disease frequently had its origin in an animal being driven fast immediately after feeding, or drinking a large quantity of water. One of the symptoms was a heaving of the flank, as if the horse was trying to get rid of the air, which it could not pass off through the windpipes. As to the mode of treatment a confirmed case was incurable, but in the way of alleviating the disease attending properly to the food was worth all the heave powders out. The best food was bruised oats, cut hay, slightly damp, and good, clean oat straw, and it should be given in small quantities, and at frequent intervals. During the day the supply of water should be restricted. Carrots, too, were good in this and all chest diseases. Administering large quantities of hog's lard, lard pellets, &c., had the effect of mitigating the symptoms for a time. These acted mechanically, by pressing down the stomach and relieving the diaphragm. He had known this plan to be restored to, accompanied with the withholding of water for twenty-four hours, when a horse affected with the heaves was brought to a fair to be sold. If there was any suspicion of such a trick, the best thing to do was to give the horse a good drink of water and a good gallop, and it would soon be discovered whether it was broken winded or not. Mr. Smith went on to speak of what is called the horse distemper, which generally shows itself in the formation of an abscess in the sub-maxillary space between the jaws, and of certain diseases of the mouth, shoulder, &c., and concluded by explaining the various points to be attended to, when the "soundness" of a horse was matter of investigation. Mr. Smith was warmly applauded at the close of his lecture.

Mr. John Barwick moved a vote of thanks to Mr. Smith for his able and interesting lecture. He said he was sure every gentleman present must have been pleased with it, and must have been edified by the information it imparted.

Hon. H. Ruttan seconded the motion which was put from the chair and passed unanimously.

Professor Buckland said he wished to offer a few observations, and proceeded to explain the action taken by the Board of Agriculture, in inducing Mr. Smith to come to this country as their veterinary surgeon. They had selected that gentleman, chiefly on the recommendation of Professor Dick, of Edinburgh, one of the oldest and ablest teachers of the veterinary art in the mother country, and he had brought with

him testimonials to his ability of the highest order. Coming among us with such high qualifications, he hoped he would very soon be able to establish in this neighbourhood, a remunerative and even a lucrative business, and that he would be the means of diffusing valuable information by instructing young men who might come to Toronto to attend lectures on agricultural subjects. Indeed it was anticipated that his own chair of agriculture in the Provincial University would be strengthened and made more useful than it otherwise would be, by there being a competent person to teach the veterinary art, both in its theory and its practice. (Hear, hear.) Prof. Buckland then congratulated the agriculturists present on their meeting for the first time in this Agricultural Hall, which was designed ultimately to afford accommodation for an agricultural collection—specimens of our cereal products in the grain and in the straw, of the soil of various sections of the country and of the subjacent rocks; models of agricultural implements; specimens of morbid anatomy of the horse, to illustrate the veterinary art, &c., &c. With the co-operation of farmers throughout the Province, a most valuable collection might thus be formed. (Hear, hear.) In conclusion, Professor Buckland said it was with very deep regret that he had heard this afternoon on the show ground, of the decease of an old and valued friend of the Association, and one who, he might say on this occasion, was the originator of the idea of establishing veterinary teaching in this country,—he referred to the death of their esteemed and venerated friend the Hon. Adam Fergusson. He had been informed to-day that Mr. Fergusson died very suddenly last night. Though he departed full of years and full of honours, they could not, as an Agricultural Association, receive without the deepest pain the intelligence of the death of their old and valued friend. (Hear, hear.)

Mr. W. Smith, Leeds county, made a few observations on the importance of veterinary instruction, and said he felt it would have been worth his while to travel all the way he did to the show, if it had only been to listen to the valuable lecture they had heard to-night.

Hon. Mr. Ruttan expressed his approval of the remarks of the gentleman from Leeds.

Professor Buckland said there was a gentleman present from Lower Canada, who was well known from his connexion with agriculture, and his having for some time conducted the Agricultural Journal of Lower Canada. If that gentleman had any remarks or suggestions to make, he was sure all present would be delighted to hear him.

Mr. Perrault, having been thus called upon said he had attended several Exhibitions in Upper Canada of late years, and had been happy to observe constant improvement each successive

year. He had been prepared by the Exhibition last year in London to see something very great in Toronto, but he must say that the display here, in several departments, was far superior to what it was in London. He had especially remarked this in the display of Ayrshires. He had seen this breed in almost every country of Europe, and in Lower Canada it was in much favour, because there they were in a condition which made them go more into dairying than into feeding cattle. He had seen in Upper Canada cattle of the Angus breed, and Devons and Herefords, to a far greater extent than they existed in Lower Canada, but he could not understand why it was that they were imported, in competition with Durhams, which were well known as the best breed for feeding purposes. On the continent he had met with many Ayrshires and Durhams, but not with the Angus, Devon, and Hereford breeds.

Mr. T. P. Holmes, of Bedford, N. Y., said if any one doubted the propriety of filling this Hall with agricultural specimens, as Professor Buckland had said was the intention, a visit to the Agricultural Museum at Albany ought to satisfy him of the value of such collections.

Mr. J. Foote, of East Durham, spoke shortly of the importance of having the rising generation of farmers instructed in the veterinary art. The circumstances of the Province were scarcely such as to support veterinary surgeons throughout the country, and it was therefore the more necessary that young men entering on farming life should acquire some practical knowledge in that department. In that view he was happy to understand that lectures on the veterinary art were to be given by Mr. Smith.

Mr. Wilson, of Chatham, urged the propriety of inducements being offered by the Association in the way of premiums, to bring out some good and efficient tile machine. He suggested also that, with a view to the benefits of improved stock being brought within the reach of the whole farming community, the Montreal Steamship Company, as a condition of receiving the subsidy, should be bound to bring out, free of charge for conveyance, such stock as it might be desirable to import, each county in succession receiving a supply.

The President thought Mr. Wilson's suggestion about the importation of cattle impracticable, and said it was a great matter that the Montreal Steamship Company were willing to carry cattle at reasonable rates, considering that the Cunard Company would not carry them at any price. As to tile machines, if he had the clay on his farm, instead of wishing to manufacture tiles for his own use, he would get a tile maker to bring his machine along and manufacture them for him at so much a thousand. As to the remarks of Mr. Perrault, that gentleman, coming from Lower Canada where all the cattle they had were small things, so small that you

could carry one under one arm and another under another—(laughter)—probably thought that in Upper Canada we were advancing too fast, and therefore objected to our importation of Devons and Herefords. He hoped the remarks of their Lower Canada friend would induce some of the Upper Canada stock raisers to send down cattle to Montreal to the Show there next year, in order that we might carry off some of their surplus money, which they accumulated by making us pay too dear for other things. (Laughter.)

Mr. Stock, Flamboro', asked Mr. Perrault to say how the best specimens of cattle he had seen here compared with those in England.

Mr. Perrault said that, putting out of view some few specimens of extra animals in England, the cattle in Canada of imported breeds, he thought, would compare favourably with cattle in England.

#### MEETING OF THE AGRICULTURAL ASSOCIATION.

The annual meeting of the Agricultural Association was held in one of the offices on Friday Morning, commencing at 10 o'clock—the President, F. W. Stone, Esq., in the chair.

The Secretary, Mr. Hugh C. Thomson, having called the list of delegates from county and other societies, the following answered to their names:

ADDINGTON.—George Lake, Camden; John Sharp, Earnestown.

BRANT, EAST.—George Stanton, Paris.

BRANT, WEST.—J. B. Merritt, Scotland; Daniel Perley, Brantford.

BROCKVILLE.—J. W. Hough, C. Sibbald.

DURHAM, EAST.—Aaron Choate, Port Hope; Nathan Choate.

DURHAM, WEST.—S. Wilmot, Newcastle.

ELGIN, EAST.—Stephen Wade, St. Thomas; James Armstrong.

FRONTENAC.—Henry Robinson, Ballynahinch; E. Jackson, Kingston.

GLENGARY.—Archibald Fraser, Fraserfield.

HALTON.—James Young, Georgetown.

HAMILTON.—George Roach, Peter Grant.

HASTINGS, NORTH.—M. Kerr, Tweed.

HASTINGS, SOUTH.—George Taylor, Belleville; Alexander McLaren, Tyendinaga.

KENT.—Duncan McVicar, David Wilson, Chatham.

KINGSTON.—George Baxter, Kingston; M. Flanagan.

LANARK, NORTH.—Jno. Menzies, Almonte.

LANARK, SOUTH.—Hon. R. Matheson.

LENNOX.—John Stevenson, Napanee; Wm. Gibbard.

LEEDS & GRENVILLE.—W. Smith, Thos. Newsome,

LEEDS, SOUTH.—Isaac Briggs, Gananoque; Oliver D. Cowan.

LINCOLN.—J. C. Rykert, St. Catharines; James Seymour.

MIDDLESEX, EAST.—Colonel Johnson, London.

MIDDLESEX, WEST.—Malcom McArthur, Lobo.

NIAGARA.—S. J. J. Brown, H. J. Miller.

NORTHUMBERLAND, EAST.—G. S. Burrill, Cobourg; George Roddick.

ONTARIO, NORTH.—Robert Spears, Uxbridge.

ONTARIO, SOUTH.—John Sheir, Whitby; W. Laing, Whitby.

OXFORD, NORTH.—John Barwick, Woodstock; Wm. Grey, Woodstock.

OXFORD SOUTH.—Jonathan Jarvis, Ingersoll; Michael Stover.

PEEL.—John Tilt, Derry West; R. A. Hartly, Edmondton.

PERTH.—R. Modervell, Stratford.

PETERBOROUGH.—John Walton, Peterborough.

RENFREW.—Alex. Stewart, White Lake.

TORONTO.—W. Sharp.

VICTORIA.—John Gibb, Lindsay.

WELLAND.—A. C. Scholfield, Port Colborne; Edward Jones, Thorold.

WELLINGTON, NORTH.—J. M. Fraser, Elora.

WELLINGTON, SOUTH.—Col. Saunders, Guelph.

WENTWORTH, NORTH.—W. D. Donaldson, West Flamboro'; William Dickson, West Flamboro'.

WENTWORTH, SOUTH.—James Calder, Carluke; Jacob Rymal.

YORK, EAST.—Thomas A. Milne, Markham; J. P. Wheler, Scarborough.

YORK WEST.—John P. Bull, York Township; E. C. Fisher, Etobicoke.

TORONTO HORTICULTURAL SOCIETY.—J. D. Humphreys, J. C. Small.

LONDON DO.—Adam Brown.

ST. CATHARINES DO.—John Holder.

BOARD OF ARTS.—Dr. Beatty, Dr. Craigie, Professor Hind, Professor Buckland, A. Brunel, W. H. Shephard, W. Edwards, W. Sharpe.

REPRESENTATIVES OF MECHANICS' INSTITUTES:—Thos. Stock, Waterdown; E. A. McNaughton, Newcastle.

#### ELECTION OF OFFICERS.

The President said the first business was the election of officers, and the first officer to be elected was the President for the ensuing year.

Mr. Barwick had much pleasure in proposing that Asa A. Burnham, Esq., of Cobourg, first Vice President of the Association, be the President during the coming year.

Hon. H. Buntan seconded the motion, which passed by acclamation.

Mr. Burnham thanked the Association for the honour they had done to him, in electing him to fill the office of President.

Dr. Beatty, seconded by Hon. John Carling, M.P.P., moved that James Johnston, Esq., of

London, the second Vice President, be the first.—Carried unanimously.

Mr. W. Ferguson said he had much pleasure in proposing J. C. Rykert, Esq., M.P.P., for Lincoln, as second Vice President. He believed that that gentleman had good claim to the position of second Vice President, and ultimately President of the Association, one of the highest honours that could be conferred by the people of this country. Mr. Rykert was well known as a practical farmer and stock breeder, and the appreciation in which he was held by his neighbours was shown by the fact that they had selected him to represent them in Parliament. He thought the Association could not make a better choice for second Vice President, than by electing Mr. Rykert.

Hon. D. Christie, M.L.C., had great pleasure in seconding the nomination. He thought Mr. Rykert was well deserving of the position which some of his friends desire to assign to him.

Mr. Aaron Choate begged to nominate Thos. Stock, Esq., of East Flamboro, a gentleman whose acquaintance he had only made since he came to the present Show, but who, he was satisfied from all he knew and had heard of him, would fill the position worthily.

Mr. Wilson seconded the nomination of Mr. Stock, and made some remarks finding fault with the managers of the Association for not adopting better measures to make the delegates acquainted with each other, when they came from distant localities to the Provincial Show, that they might consult as to who were the persons most fit to be their officers. Whether justly or not, there was an impression abroad that the members of the Board of Agriculture aimed at managing things so that the delegates would be kept in the dark, and have as little influence in these matters as possible.

Mr. T. A. McIne, seconded by Mr. R. A. Hartley, nominated J. P. Wheler, Esq., of Scarborough.

A show of hands being taken and counted, the vote was found to stand thus—for Mr. Rykert, 45; for Mr. Stock, 12; for Mr. Wheeler, 10. Mr. Rykert was accordingly declared elected.

Mr. Rykert begged to thank the delegates for the compliment they had paid him. He might not be generally known to the agriculturists of Upper Canada as a practical farmer, but those who were acquainted with his farm, he believed, would say it compared favourably with farms generally in Western Canada. He would not claim on that account a first place in this Agricultural Association, but he would claim that agriculture had no warmer friend in this Province than himself. He lived now, and had lived nearly all his life on a farm, and in electing him to the office of second Vice President, they elected one who would bring to the affairs of this Association some degree of energy. He was glad to hear the other day the testimony of

personages of high authority that our Exhibition compared favourably with those of the mother country, but he was satisfied that if they all put their shoulders energetically to the wheel, they could make yet a still more creditable appearance. He again thanked the Association for the honour they had done him, and hoped the confidence they had reposed in him would not be misplaced. (Applause.)

Mr. Young moved that R. L. Denison, Esq., be re-elected Treasurer. He said Col. Denison had so long occupied this position, and had filled it so creditably to himself and with such satisfaction to the public, that it was unnecessary for him to add a single word in support of the motion.

Mr. Rykert seconded the motion, and it passed unanimously.

Col. Denison thanked the Association for this renewed expression of their confidence in him. During the many years he had filled this office, he had endeavoured to do his duty, and he thought the same thing might be said of all who had in their hands the management of the affairs of the Association. They were all good, energetic men, and by adding fresh blood to the management, by the election of such men as had been elected to-day, he had no doubt the Association would continue to go on prosperously. With the permission of the President, he would now read the financial statement and audit of accounts.

The President having asked if the financial statement should be submitted, it appeared to be the general feeling that it should be postponed till the regular business was disposed of.

#### THE NEXT EXHIBITION.

Mr. Rykert said that last year he advocated the interest of a small locality called St. Catharines, and his proposition that the show should be held there did not meet with great favour. He made that proposition because he was opposed to the centralization of the Exhibition in only four localities. He was in favour of carrying it from one end of the Province to the other, and not compelling the places where it was held to erect permanent buildings. In proposing that next year's Exhibition should be held at Kingston, he did not abandon the position he took up last year, and he trusted that, when the proper time came, he would get the aid of his Kingston friends in getting it taken to St. Catharines, Guelph, Woodstock, Cobourg, Brantford, or some other town. At present, however, he hoped there would be no amendment to his motion that the Show should be at Kingston next year. He thought this was due to the Kingston people. We had now had three successive Shows in the West, and it was right that the next should be held in the East.

Hon. Mr. Carling seconded the motion. He differed, however, from Mr. Rykert, in the views he had expressed about holding the Pro-

vincial Show in small towns. He did not think it was the object of this Association to hold the Fair in any particular place for the benefit of that place. What they ought to have in view should be to hold it in places where the greatest number of people could be brought together, and, where the best accommodation in the shape of lodgings, &c., could be provided for them. He was happy to know that the city of London was such a place. Last year 23,500 tickets were sold in London on the Thursday; and on the same day in Toronto only 22,000 tickets were sold.

Hon. Mr. Ruttan had much pleasure in concurring in the motion to hold the next Show at Kingston. He argued also with Mr. Rykert that the Exhibition should not be confined to a few principal cities. The Association received a grant of public money, and its object should be to extend the advantages of that grant to all parts of the country. He would push the Exhibitions into the back country, so as to enlist in their favour the sympathies and the co-operation of all classes of the community. He would have them held back in Ottawa, Perth, Goderich, &c. He was sorry to see that a number of the members of the Board of Agriculture had gradually fallen into the centralization system, forgetting that it was their duty to see that the interest of the people of all parts of the country should be attended to.

Hon. David Christie said Mr. Ruttan had complained of the Board of Agriculture as giving its influence to carry out the centralization system.

Hon. Mr. Ruttan—I complained in their acquiescing in it.

Hon. Mr. Christie said it was the duty of the Board of Agriculture to acquiesce in the expression of popular opinion as given at the annual meetings of the Association. But he knew of no action which the Board of Agriculture had taken committing itself to centralization. Where the Exhibition should be held was decided at the annual meetings by the votes of the delegates, and he could not permit the impression to go abroad that the Board had committed itself either for or against the centralization scheme.

Hon. Mr. Ruttan said he had spoken, not of the Board, but of several members of the Board.

Col. Denison said it was necessary, before the motion was put, that the delegates from Kingston should come forward and say what offer of money they would make, and what guarantee they would offer as to buildings for the proper accommodation of the stock.

Mr. Ferguson said the Association ought to have sufficient confidence in the honour of Kingston, without getting the pledge demanded by Col. Denison. Kingston was the first to put up a permanent Building. It was the first to erect a Crystal Palace, and Toronto followed suit, then Hamilton, and then London. Kingston

last time had better buildings than there were at the previous Fair at Toronto, and he was quite satisfied that next year Kingston would have better buildings than Toronto had now.

Dr. Beatty said that the Treasurer, in requiring a pledge, was only carrying out the law agreed upon by the Association.

Col. Denison said it was not pleasant to insist upon it, but he did not think the Association could vote upon this motion until it had a pledge from Kingston in writing.

Mr. Ferguson—You have no right to demand anything of the kind.

Mr. Flanigan, Warden of Frontenac, Lennox and Addington, said the city of Kingston and the county of Frontenac were acting quite unanimously, and would do everything in their power to make the grounds all they should be, and to put up every necessary building. The Association need not be afraid but everything necessary would be done. They would find in Kingston better accommodation than they had ever had anywhere else.

Mr. Gildersleeve, Mayor of Kingston, said he held in his hand authority under the seal of the city of Kingston, authorizing him and the members of the Corporation who accompanied him to give a pledge to any reasonable extent the Association might demand.

This paper was handed in and some further discussion occurred, in which Mr. Ferguson, Mr. Rykert, Col. Denison, and Col. Thomson took part. In the course of this discussion a resolution, passed in 1858, was read, affirming, "That it is not in the power of this Board to fix the location of the Exhibition in the year 1860, or any year beyond next year, but that in the opinion of the Directors the Exhibition should not in future be held at any place where there are not permanent buildings erected, or assurance given that permanent buildings will be erected, and also that ample accommodation will be offered." The motion that the Exhibition next year should be held in Kingston was ultimately adopted unanimously.

Hon. H. Ruttan gave notice that at the annual meeting next year, he would move that the resolution which had just been read be rescinded.

#### THE HON. ADAM FERGUSON.

Col. Thomson said that since they had assembled in Toronto, they had heard announced the death of an old friend of this institution, and he was sure some such resolution as that he was now about to propose would receive the cordial approval of the meeting:—

"That this Association have learned with deep regret that, since the meeting of the Association on this occasion, one of the first and most indefatigable friends of the institution has been called from the scene of his earthly labours, and they desire to record their high estimation of the value of the services of the late

Hon. Adam Fergusson, of Woodhill, and the esteem in which he was held by the Board of Agriculture, of which he has been a member since its formation, and also by the farmers of Canada at large."

He said that having had so long and intimate an acquaintance with Mr. Fergusson, he could not submit this resolution without making one or two remarks. Mr. Fergusson was one of the first who was consulted when the getting up of this Association was first spoken of. He thought it was a difficult undertaking, but consented to give his assistance, and he did assist most efficiently. He [Col. Thomson] was President at the first meeting of the Association, and requested Mr. Fergusson to prepare an address. He did so, and it appeared in their Transactions as the first of the annual addresses delivered before the Association. And from that day to the present time Mr. Fergusson had always been ready to give the Association his earnest assistance in everything which tended to advance the prosperity of the agricultural interests of Canada. [Hear, hear.] It was owing to the indefatigable exertions of Mr. Fergusson and a few others that the Association had attained its present position of prosperity and usefulness.

Hon. D. Christie said—I have a melancholy satisfaction in seconding the resolution which has just been moved. I have had the honour and advantage of knowing Mr. Fergusson almost from childhood. He was my father's friend, as well as my own, and I was taught to look up to him as an honest man, and I believe I may say a Christian man. He was long associated, as many of you know, with the advancement of Agriculture in the mother country, being one of those who had the honour of originating the Highland Society of Scotland. (Hear, hear.) When he came to Canada, he was not backward to engage in a similar work, and he has lived to see the interests of Agriculture most successfully advanced in this country. While he was amongst us, he was always foremost in every good work. I have had the honour of being associated with him as a member of the Board of Agriculture since its formation, and I can cheerfully and heartily bear testimony to the truth of what has been said by our friend, Col. Thomson, that on every occasion when it was in his power to be present, he has used his utmost endeavours to promote the success of the Agricultural Association. But I know that no words of mine are necessary to endorse his many virtues. His works follow him. (Hear, hear.)

The resolution passed in solemn silence.

#### VOTES OF THANKS, &c.

On motion of Mr. Asa A. Burnham, seconded by Col. Johnston, a vote of thanks was passed to the retiring President, Mr. Stone, for his able and valuable services during the past year.

Col. Thomson brought up the draft of a new code of Rules and Regulations of the Agricultural Association, prepared by a committee appointed for the purpose.

After some conversation, it was agreed, on the motion of Mr. Grey, of Woodstock, to defer the consideration of these rules till the next annual Meeting of the Association.

On motion of Mr. Grey, seconded by Mr. M. Stover, the thanks of the Association were voted to the Local Committee for their valuable services in contributing to the success of the Exhibition.

On motion of Mr. Ferguson, the appointment of the Local Committee for the next Exhibition was referred to the Council of the Association.

The meeting then separated.

### The Close of the Exhibition.

It has been usual in former years to wind up the proceedings of the Exhibition with a public meeting on the grounds on Friday afternoon, at which the Prize List was read, and a written address read by the retiring President. This year the meeting was held, but the prize list was not read, probably because it was considered to be unnecessary after its publication in the *Globe* and *Leader*, and the retiring President did not read an address. Some other interesting proceedings were instituted. Shortly before two o'clock the very efficient Cobourg Brass Band stationed themselves on the stand at the east end of the machinery shed, and their excellent music soon had the effect of collecting a large crowd. After the assemblage had been entertained by the band for about half an hour, the retiring President, the President elect, and other officers of the Association came upon the stand, and it was announced to the crowd that they would have the pleasure of witnessing a procession of the horses and cattle, which had been adjudged worthy of the prizes of the Association. This very interesting ceremony occupied about twenty minutes, and many were the exclamations of admiration as the splendid animals were marched past the stand.

F. W. Stone, Esq., then came forward, and said it had been usual at former Exhibitions for the retiring President to deliver an address before the close of the fair. From various causes he had been unable to prepare an address to deliver on the present occasion. He could not, however, allow the meeting to separate without expressing his sincere gratification at the unusual display of stock, implements, &c., witnessed at the present Exhibition. It was matter of much importance to him that he was able to congratulate them on its complete success. [Cheers.] But, instead of delivering an address himself, he should now call on the President of the Board of Agriculture, who had been con-

nected with the Agricultural Association since its commencement, to give to the meeting some idea of its progress up to the present time.

Col. Thomson said that Mr. Stone deserved credit for the moral courage he had displayed in bringing to an end the practice which had hitherto prevailed of an address being annually delivered at these shows by the retiring President. He (Col. Thomson) had been asked to say a few words on this occasion, perhaps for the reason that they gave him the credit of being the father of this institution. If this was the case, he certainly had reason to be proud of his offspring. It had grown to be a very respectable boy. [Laughter.] On this occasion we had had a display of the products of the country, creditable to every section from which they had come. As regarded the stock, the numbers might not have increased very materially, but every one who had seen the animals exhibited on this occasion would admit that the quality of stock shewn was very superior. [Hear, hear.] In the implement department also, there was a vast improvement over all former years. He believed we never before had had so good a display of implements as there had been on this occasion. The display of the products of the field and of the garden was very satisfactory. The articles of ladies' work, some said, were not so numerous as those shown last year at London but it was admitted on all hands that those which had been exhibited here were of the first quality. He trusted that year by year this exhibition of the products of Canadian industry would become still more creditable to the country. (Cheers.) One generation was fast passing away to make room for another. He had the melancholy duty of announcing that one of the most prominent members of this Association had just passed away from this scene of action—he alluded to the death of the Hon. Adam Fergusson. Mr. Fergusson had been a prominent member not only of the Association, but of the Board of Agriculture, and was amongst the most successful breeders of the country, having been one of the first to introduce the breed of short-horns into Canada. He might mention that the Association had this day passed a resolution, paying a fitting tribute, and it was unnecessary therefore that he should on this occasion say anything farther as to the worth of their departed friend. He hoped they were all sensible of the great blessing they had enjoyed in the weather being so favourable on this occasion. We had reason also to be thankful to the Almighty for his goodness with reference to the ingathering of the fruits of the earth during the present season. They had proved to be much more abundant and much finer than at an earlier season he had expected. Much apprehension had been felt on account of the dryness of the season, but the kindly rains came at last, and, with the exception of hay, he believed the crops were very fair throughout the country at

large. Since the last meeting of the Association he had had an opportunity, like many of those whom he now addressed, of visiting the old country. At the Great Exhibition he was one of seventeen who judged the articles in use for human food from all parts of the world. We are apt to think that our own country produced greater abundance of food and of finer quality than any other country. This idea a visit to the Exhibition would have shown to be too flattering to ourselves. In some countries, it was true, they lived on materials coarser than our finest wheat, and after examining specimens of the food raised in every country in the world, he found they were not in general equal to our own products. But he was bound in honour and in justice to the Australian Colonies to say that their wheat was superior to anything he had ever witnessed before. We must acknowledge they beat us in the article of wheat, the samples they showed being far finer and of more uniform white appearance than any wheat in Canada to his knowledge. Our wheat, however, took a very creditable rank at the Great Exhibition. We had a sample of oats also grown near Hamilton which was as fine a sample as any brought from any part of the world. The other samples of oats, however, sent from Canada, were inferior. Our peas were very good and received high commendation. The countries lying south of us showed the best samples of corn, which they produce in great abundance and of very fine quality. He would now call upon the Mayor of Toronto, to whom and to the Corporation the Association were under great obligations for the very ample accommodation they had on this occasion, to make a few remarks. (Cheers.)

Mr. Mayor Bowes, on behalf of the citizens of Toronto, begged to thank the farmers and mechanics of the country for the splendid display they had made on this occasion. He thought the retiring President had acted judiciously in departing from the custom of delivering a written address. These addresses were generally for the purpose of apologizing for defects on the part of the exhibitors, or on the part of those managing the Exhibition. But on this occasion he did not believe there had been a single defect to apologize for. The farmers and mechanics of Canada have reason to be proud of this Exhibition. He was sorry he was not a practical farmer himself, that he might have had his share with them in the glory of the testimony which was borne by the noblemen from England and Ireland, to the excellence of their cattle, the magnificence of their horses, the superiority of the products of the mechanical genius of the people of this country, which were now exhibited on those grounds. (Cheers.) Looking at what was the mainstay of the wealth of this country, he might be allowed to say that the farmers of Canada are Canada's aristocracy. [Cheers.] At the same time we had reason to

be proud that the nobleman now presiding over the destinies of this country, as its Governor, came forward and claimed respect on the ground that he too is a practical farmer. [Cheers.] The crown of Great Britain had never been properly represented here before. What we wanted was to have at the head of the affairs of this country either a business man or a farmer, that the resources of this great country might be intelligently understood and properly developed. The Mayor concluded by again thanking the exhibitors, on behalf of the Corporation and citizens of Toronto, and of the country at large, for the splendid display they had made on this occasion.

Col. Thomson, then begged to introduce to the assemblage Asa A. Burnham, Esq., elected that day as President for the ensuing year.

Mr. Burnham was received with cheers. He said he was proud of the honour which had been conferred upon him, and hoped that at the close of his term of office the Association would not regret the choice they had made. If he failed in any respect, it would not be from the want of an earnest desire to promote to the utmost the objects of the Association. (Cheers.)

Col. Thomson then proposed a vote of thanks to the Cobourg band for their valuable services, although he regretted that Toronto had not produced a band which could carry off the prizes from them.

The motion passed by acclamation.

Three loyal and hearty cheers were then given for the Queen, after which the band played the National Anthem. Three cheers, at the request of the Mayor, were given for the Agricultural Association, and the exhibitors and judges. Other three were given, at the request of Col. Thomson, for the ladies of Canada. Cheers were also given for the Cobourg band, the Mayor of Toronto, and the Governor-General, and with these proceedings terminated the Seventeenth Provincial Exhibition, in many respects the most successful which has ever been held.

#### THE RECEIPTS AND ATTENDANCE.

The total receipts of the Exhibition now closed amounted to about \$16,000; thus made up:—\$2,000 from the County Council, and from the City, Riding and County Societies; \$1,000 for the use of booths and stables; \$2,000 from members' tickets; \$750 for 3000 tickets sold on Tuesday; \$3,750 for 15,000 tickets sold on Wednesday; \$5,500 for 22,000 tickets sold on Thursday; and \$1,000 for 4,000 tickets sold on Friday; total, \$16,000—being \$3,500 in excess of the receipts at London last year, which from all sources were \$12,500. It was stated at the meeting of the Association yesterday that in London on the Thursday 23,500 quarter dollar tickets were sold, while on the corresponding day in Toronto the number was but 22,000. This fact

may indicate that, from the greater accommodation of visitors in Toronto, the pressure, instead of being concentrated on one day, was somewhat more equally distributed over the week. Be this as it may, the total number of visitors to the show has been considerably greater in Toronto than it was at London. Last year the number of quarter dollar tickets sold (two of which on Tuesday or Wednesday are necessary for the admission of one person,) was 38,568, yielding \$9,542. This year the number sold was 44,000, yielding \$11,000, in addition to the amount received from members' or season tickets.

#### THE REMOVAL OF THE GOODS, &c.

The Exhibition proceedings having been closed by the President, at two o'clock, many of the exhibitors proceeded to remove their goods. The sewing machine manufacturers, who had almost exhausted themselves during the week, in explaining to visitors the superior qualities of their machines, were among the first to commence packing up, and silence reigned in the eastern section after three o'clock. The fruit growers also commenced stowing away their grapes, plums, pears and apples, or presented them to their friends. Many of the visitors did not wait to be asked to partake of the dainties, but quietly helped themselves, and when remonstrated with gave the growers a "puff" for the excellence of the fruit. The ladies' work in the gallery had, to a great extent, disappeared. Outside, cultivators, ploughs and implements, were placed on waggons and conveyed to the railway depots to be in readiness for the morning trains. Only a few cattle and sheep were taken away before six o'clock in the evening. On Saturday morning however, the work of demolition commenced in earnest, and by dusk there was little left of the Great Exhibition of 1862 but the buildings themselves.

#### Foreign Opinions of the Exhibition.

[It will be interesting to our readers to know the views taken of our recent Show by intelligent persons at a distance, unconnected with the Association. We take the following from two leading journals belonging to the State of New York.—EDS.]

THE PROVINCIAL FAIR AT TORONTO, C. W.—The annual exhibition of the "Agricultural Association of Upper Canada," was held at Toronto last week, beginning on Tuesday and closing on Friday. This, we believe, is the 17th Exhibition of the Association, which has grown up from small beginnings to a position of great influence and usefulness. It has lately alternated between the four principal cities of the

Province—Toronto, Hamilton, Kingston and London—at each of which places permanent structures have been erected for its accommodation.

The favorable weather of the last week, ensured for the exhibition a good degree of success. The entries were very numerous in the principal departments, and the display, on the whole, highly creditable. Canada possesses a great deal of improved stock. Of cattle, the Short-horns, Ayreshires, Devons and Galloways have been imported in large numbers, and these, with their progeny, constitute a basis for an improved stock of which any country may well be proud. The Short-horns were most numerous at the exhibition, presenting many valuable herds in different sections of the Province. There were also a good number of the other breeds, as also of sheep and swine; but the limits of this article will not permit anything like a notice in detail of their merits. Of sheep, the long-wooled varieties predominate. Of swine, of which there was a very large and creditable show, the Berkshires, Suffolks and Yorkshires formed the principal attraction. There was a fine display of horses, several of them good imported animals, and we should think a visible and valuable improvement, from year to year, in this class of stock.

The Canadians have made rapid progress in the manufacture of farm implements and machinery, since the Association was organized, and their exhibitions, instead of being made up chiefly of American articles, as formerly, now consist chiefly of articles produced by Canadian mechanics. Almost every article required on a farm, from a portable steam engine to the most delicate garden implement, is now produced in their workshops. These were well represented at Toronto. In other branches of manufacture, such as woollen goods, paper, and various other articles, there has been a considerable augmentation, many of the establishments being owned by Americans who have lately settled in Canada. There were good specimens of most of the articles of domestic manufacture on exhibition.

The galleries of the "Crystal Palace" were devoted principally to the display of the finer specimens of goods—of paintings, musical instruments, needlework, embroidery, printing and bookbinding, and a multitude of articles interesting to the visitor, and affording good evidences of improvement. We noticed, among these articles, two large maps of Canada—one a lithograph, and the other a splendid copper plate engraving, five by six feet—published by Messrs. TACKABURY BROTHERS, of London, C. W. It is a fine specimen of work (done, we believe, in New York), and one of the best maps we have lately seen. To those of our readers who wish a map of Canada, we can commend this one as very desirable.

The excellent fruit season has produced, even

in this cold climate, some fine specimens of the different varieties. There was a large show of apples, some excellent pears and peaches, and a very good display of grapes—mostly, however, of hothouse growth. Of flowers there was nothing to boast of. The seed and vegetable department was excellent, the specimens being generally superior.

An important feature in the week's proceedings was the presence in Toronto of Lord MONCK, Governor General of British North America, Lord MULGRAVE, Governor of Nova Scotia, and several other distinguished noblemen and gentlemen connected with the British and Provincial Governments. The usual ceremonies of receptions, addresses and replies, dinners, speeches, balls, &c., were of course indulged in. The principal affair connected with the visit of the Governor-General to the exhibition, was a dinner given to his Lordship, at which some five hundred gentlemen sat down, and at which speeches were made by several distinguished men. The speech of the Governor General was a creditable performance, both in point of matter and as a specimen of ready oratorical powers. He is, "at home," an extensive farmer, and talked agriculture "like a book." His speech, however, was statesmanlike, and very taking among her Majesty's subjects in Canada. One passage was somewhat significant, and rather interesting to the few Americans present. The Mayor having alluded to the possible danger of a war with the United States, and to the late troubles in the Canadian Government on the militia bill, the Governor, in response, said he was in a position to state that his attention, and that of those who are responsible for the Government, had been directed to a system of defence which would soon be promulgated, and which he believed would be acceptable to the militia and people of the Provinces. The remarks of Lord MULGRAVE were plain and sensible—and, on the whole, we think the Queen need not be ashamed of her representatives in America.

The weather during the exhibition was delightful, and the attendance large. Some fifty thousand tickets were sold, which, with the admission on members' tickets indicates the presence of a large number of people. During the week, meetings for discussion were held at the new Hall of the Board of Agriculture, but they were thinly attended. This hall has been erected for the purposes of the board, at a cost, for land and building, of nearly \$20,000. The first floor is occupied by JAMES FLEMING & Co., Seedsmen to the Board, as a seed-store; the second floor for offices for the Board; and the third for a public hall, in which is to be gathered a museum, &c., after the plan of the Agricultural Hall in Albany.

The officers of the Society and of the Board are attentive to strangers, and do all in their power to make them feel at home. We are under especial obligations to Prof. BUCKLAND, who

fills the Chair of Agriculture in the University of Toronto, who took us to his hospitable house, and made our visit both instructive and agreeable to us, and we hope useful to our readers.

We had designed to say something of the public buildings in Toronto, the literary and charitable institutions, &c., but want of space forbids at present.—*New York Argus.*

### The Provincial Fair.

During the past week the Seventeenth Annual Exhibition of the Provincial Agricultural Society was held at Toronto, and our Canadian brethren have reason to congratulate themselves upon the success which marked its entire course. The weather was all that could be desired, and the entire people pleased with themselves and the prospects of an agreeable gathering. It was our good fortune to spend the closing day in looking over the various departments of the Show, and we give RURAL readers, as briefly as possible, a summary of what is to be witnessed, together with the impressions received in viewing the productions of our trans-Ontario friends.

The *Grounds* devoted to the display comprised nearly forty acres, and are situated about two miles from the centre of the city. Avenues leading to the point of attraction were numerous, and no jostling or crowding was observable. Entering the gate an inspection at once assured the visitor that the plans adopted in laying out and arranging buildings, sheds, tents, cattle, and horse rings, &c., were those which best met the wants of both exhibitor and spectator.

In the line of *Buildings* the committee are fairly entitled to a vote of thanks from all concerned, for the excellence of these structures was never before equalled at a Provincial Fair. Those devoted to cattle had a raised platform running through between the stalls, and a walk over this afforded excellent opportunity for observation. The horse stables were close, the comfort of the animal alone being sought, and the ring being the only fit place for exhibiting. The sheep and pig pens, and the shed for heavy machinery seemed to be the only temporary structures connected with the Society. All the others wore an air of strength and durability.

#### STOCK DEPARTMENT.

**CATTLE.**—*Durhams*—There were 125 entries of Short-horns, and, everything taken into consideration, they proved the feature of this Department of the Exhibition. Among the more prominent exhibitors were Geo. Miller, Markham; Fred. W. Stone, Guelph; John Snell, Edmonton; J. White, Georgetown; George Cooper, Toronto; Donald Robertson, Queenston; Gavin Craig, Grafton; John Miller, Brongham; James Kirkland, Haldimand; H. P. Welford, Woodstock; John Walton, Peterboro; John Dew, Yorkville; Arthur Hogge, Guelph, and

Adam Fergusson, Waterdown. A very large number of single entries were made, conclusively showing that the breed is fast becoming disseminated,—and many of these we would be glad to specially notice, but want of space compels this omission. The selection by the judges of the chief male representative of Durham Stock,—“Prince of Wales,” owned by Geo. Miller, Esq., Markham, met, we believe, with general concurrence. He is a truly magnificent animal, and we doubt not his owner was well pleased at the honors achieved. The “Prince” won the first prize for Durham bulls for four years old and upwards, \$36,00; first for Durham bull of any age, Association’s Diploma; first for best bull of any age or breed, diploma and silver medal; first for best animal in the yard, male or female, diploma and silver medal; and the special prize, \$60,00, for best Durham bull of any age. Rather a rich harvest for one animal to gather, and when we consider that the competition was lively, that excellent stock surrounded the fortunate competitor, we think a little pride on the part of Mr. Miller was justifiable.

*Devons.*—Passing to the apartment occupied by the Devons a goodly array was noticeable. The friends of this breed were outnumbered by the advocates for large stock, but the fervor with which the claims of the Devonshire representatives were presented make full amends for lack in forces. Beautiful to gaze upon, lithe and active, free from the coarseness too often perceptible in their larger neighbours, why should they not occupy a prominent position among breeders. The entries numbered 99, and some very choice animals were exhibited. John Pincombe, London; Chris. Courtice, Bowmanville; John C. Rykert, St. Catharines, and Daniel Tye, of Wilmott, each exhibited herds, consisting at least of one bull and five cows or heifers. Aside from the gentleman named, E. G. O’Brien, Shanty Bay; John Davey, Leskard; Thos. Allen, Whitby; John Goodall, Galt; J. & H. Spencer, Whitby; Jas. R. Todd, Brampton; Wm. Scott, New Hamburg; Geo. Z. Rykert, St. Catharines; John Moore, Etobicoke, and J. W. Willson, Ontario, occupied prominent positions as exhibitors, and their display reflected great credit upon their skill as breeders, and the kind of stock to which they are devoting attention.

*Heresfords.*—Here the show was light, but 29 entries being made. The breeding of Heresfords, judging from the number of exhibitors, is more limited than in any other description of cattle, there being but two competitors for the Society’s premiums, James R. McMicking, of Queenston, and Fred. W. Stone. Of the stock exhibited we can only say good to fair. There are more friends of this strain of blood in Canada, or else a striking change has occurred within the past five years.

*Ayrshires.*—These beautiful dairy cattle made quite a respectable display both in numbers and quality. The entries were 77, and the stock divided up among a large number of proprietors. Patrick R. Wright, Cobourg; R. L. Denison, Toronto, and John Torrance, Scarborough, each exhibited fine herds. Simon Beattie, and Geo. Miller, Markham; John P. Wheler, and Geo. Scott, Woburn; Hendrie & Co., Hamilton; Joseph Boyle, Flamboro; Geo. Stanton, Paris and John Miller, Brougham, each contributed freely, worthily, to complete this feature of the exhibition.

*Galloways.*—An excellent display of Galloways and Polled Angus, or Aberdeen cattle, was made. The entries were 66, and a very large proportion were choice animals. The prize for a herd was awarded to John Snell, of Edmonton, and their exhibition in the prize ring was quite a novel feature. Jas. Graham, and Arthur McNeil, Woodbridge; A. Nimmo, Kingston; John Fleming and James Sumerville, Vaughan; John Stewart, Waterdown; John McLain, Simcoe; Jas. Auld, Hamilton; Alex. Kerr, London; Geo. Miller, Markham, Jas. Metcalfe, Eglinton; A. Kyle, Ayr, and John Hunter, Exeter, each brought forward good stock. As far as we could ascertain from inquiry, this breed of cattle is gaining friends among the breeders of Canada, and it was urged that among all those who had tested their merits, and had opportunities for developing their peculiarities, they had won their way to favor.

*Grade Cattle.*—In this class some very excellent animals were shown. “Full-bloods” and “Thorough-breds” are in special repute, and the entries were but 52 for Grades. James Bellwood, Newcastle; John Gill, Grahamsville; Jacob Lahmer, Maple; Thos. Stock, Waterdown; James R. Todd, Brampton; Arthur Hogge, Samuel Hodgskin, and Geo. Morton, Guelph; Jno. Ross, Toronto; Wm. Montgomery, Islington; W. D. Jarvis, Etobicoke; Jas. Lowrie, Malvern, and John Randall, Paris, exhibited specimens which should bring Grade Cattle into much esteem.

*Fat and Working Cattle.*—A glance at this section will close our survey of the cattle. The entries were few in each class. The Fat Cattle were certainly oleaginous enough, and as far as stuffing and its results are concerned, those exhibited fairly earned the prizes. Of the working Oxen we cannot speak so favorably. There were a few good yoke, nothing superior was revealed to our examination. There were no entries for the “best team of ten,” with a prize of forty dollars.

*Horses.*—Unfortunately we arrived too late for a thorough inspection of the stables connected with the Society, and such jottings as opportunity afforded are of a desultory character. The stables are close, well barred and locked,—

and horse owners—especially unlucky competitors,—had either removed their animals, or with the keys in their pockets, kept themselves out of sight. Strange is it how soon pride in a horse evaporates when your neighbor eclipses your productions, and the animal which you fondly hoped would receive a prize draws a blank. Horsemen are peculiarly thin-skinned; and after the awards had been declared, doors were slammed to some purpose. When the grand procession of prize animals was in motion, we scanned as fully as possible the representatives of Canadian horsemanship. The number of entries was large,—more than 300,—and we looked for a remarkable display of good points. In some respects our anticipations were more than realized; in others there was an utter failure.

The show of *Heavy Draft Horses* was magnificent,—it could not be equalled on the continent outside of Canada. John Sanderson and Joseph Thompson, Markham; Robert Ferris and William Ritchie, Richmond Hill; John Wilson, Oshawa; John Shedden and James Armstrong, Toronto; James McConnachie, Orono; Wm. Jackson, York Mills; E. Foster, Humber; John Miller, Brougham; Geo. Miller, Markham; J. G. L. Pearson, York; Geo. Scott, Woburn; James Young, Mayfield; John Wilson, Ontario; A. J. Nimmo, Kingston: John Thompson, Whitby, and James Lawrie, Malvern, were among the fortunate possessors of premiums, and their stock was certainly worthy of the honors bestowed. While thus giving expression of acquiescence in the awards, we must not be understood as conceding that the heavy draft horses are all their breeders claim; There is considerable doubt as to their efficiency and utility in comparison with somewhat smaller breeds. The question is a mooted one, and strong arguments can be plied by the disputants.

*Thorough-breds* were in some force, and had their friends, no doubt; yet we would require better samples to arouse our fancy for the class. They may exhibit the "poetry of motion," with jockey mounted and running for a stake; but walking round a ring is a poor way to exhibit action, stamina, or good looks.

*Agricultural Horses* were in goodly numbers, and some very fine specimens were shown. The winners were owned by Thomas Davis, Islington; Hector Scott, Brooklin; James Cowie and Robert Armstrong, Markham; James Ferris, Galt; John Hewer, Guelph; Alex. Burgess, Agincourt; Thomas Teasdale, Grahamsville; K. Graham, Belleville; Geo. Higginbotham, Balsam; Rich. Powers, Columbus; Geo. Alton, Nelson; Thos. Gowland, York; Geo. Scott, Woburn; Chas. Pilkey, Claremont, and Robert Beith, Darlington.

*Matched Farm Horses*.—There were just a dozen span in competition. The successful individuals,—Andrew Allison, Burnhamthorpe;

Wm. Elford, Darlington; John Clarke, Brampton, possessed very excellent horses; but the entries were hardly sufficient to excite close rivalry, or fairly exhibit Canadian farm teams.

*Roadsters*.—Quite a display was made of roadsters; but nothing especially worthy was observed. This portion of the Horse Department was a failure in quality. Rochester, in the essentials, style, and action, can easily eclipse what was presented.

*French Canadian Horses*.—This breed had its representatives, and some of those shown attracted much attention. Their hardiness and power of endurance, together with the fact that "flyers" are frequent among them, entitles the breed to consideration. Did they possess a little easier action and a longer stride, the breed would be much more sought after; but they come toward you like a tornado, evidently bent upon tearing up everything. As a friend expressed himself when viewing a pair under motion, "they are rum 'uns to look at, but good 'uns to go."

*SHEEP*.—Never was there a better exhibition upon the continent in *Long and Middle Woolled* breeds. The entries amounted to more than six hundred in number, and among the animals were very many of extraordinary merit. An attempt to select even those which were deemed entitled to special note, would prove a labour requiring more time than is at our control, and more space than the *Rural* can afford. In this branch of farm industry Canada has ever had precedence, and in the recent exhibition she certainly distanced all competitors.

*Fine Woolled Sheep*.—There were excellent specimens on exhibition, but the paucity of numbers, in comparison with their coarser relatives, was such as to throw them completely into the shade. Quite certain is it that the Canadian Farmer looks for both wool and mutton, (and the present high rates for coarse wools are tending toward a confirmation of his philosophy,) hence Merinos and Saxons are not in general favor. The exhibitors were few—less, we think, than at any time in the past four or five years.

*SWINE*.—Here, too, was a large display. As, though extensive accommodations had been provided on the last day, quite a number of crates still held their occupants in close confinement. All breeds were well represented, and we could not perceive, for the numbers shown, any indications of preference. If there was any material difference the majority was with the small breeds.

*POULTRY*.—The snow of Poultry was good, where numbers are the criterion, and excellent as to quality. In the former respect the Exhibition last year at London was superior. The principal exhibitors were residents of London, and their display indicated considerable of the Chicken Fever in that locality.

**IMPLEMENTS AND MACHINERY.**—While it would be gratifying to make mention of the thousand and one labor-saving implements, and the varied mechanical formations presented, space forbids, at least for the present. Suffice it to say, the Province never appropriated so much credit to itself at any former display of the skill and handiwork of her artizans. Until very recently, the United States has been looked to for supplies in this department, but American mechanics must not allow themselves to stand quiet with the amount of perfection acquired, or they will inevitably be driven out of the market.—*Rural New Yorker.*

## MORETON LODGE NEAR GUELPH, C. W.

### Important sale of Imported & Pure Bred SHORT HORNED CATTLE!

Cotswold, Leicester and South Down Sheep,  
Berkshire and Small White breed of Pigs.

Mr. W. S. G. Knowles, begs to announce that he has received instructions from Fred. Wm. Stone, Esq. to offer

### FOR SALE BY AUCTION ON

WEDNESDAY, 15TH OCTOBER NEXT

At Morton Lodge, near Guelph, Canada West  
Thirty Imported and Pure Bred

**SHORT HORNED CATTLE,**  
One Hundred and Fifty Imported and Pure Bred  
**COTSWOOD, LEICESTER & SOUTHDOWN  
SHEEP,**

Consisting of Rams, Ram Lambs, and Ewes.  
And 25 Berkshire and small White Breed of

**PIGS,** of different ages.

The Short Horns are Imported and bred from some of the most fashionable Herds, such as Capt. Gunter's, Col. Kingscote's Messrs. Tanqueray's Ambler's Bolden's, Sandy's, Jonas Webb's, Smythe Owen's and other eminent Breeders. The Cotswold Sheep are imported, or bred from Imported Stock. From the flocks of Messrs. Ruck, Slatter, Brown, Langston, Gare, Wakefield and other celebrated breeders. The Leicesters imported from Mr. Pawlett's flock, and the Southdowns, imported and bred from the celebrated Buckland and Babraham Flocks of Sir R. Throckmorton and Jonas Webb. The Berkshire pigs, from the finest Buckland Stock. The small Wheat Breed from Capt. Gunter's

Catalogues, with Pedigrees, and other particulars, are now in preparation, and will shortly be issued, and may be had on application to Mr. Knowles, or of Mr. Stone, of Guelph.

Guelph, 8th Sept. 1862.

### THOROUGH-BRED STOCK FOR SALE

**THE** Subscriber has for sale DURHAM and GALLOWAY CATTLE, LEICESTER, COTSWOLD, and LINCOLNSHIRE SHEEP, Male and Female 10 Durham and Galloway Bull Calves—price from \$100 to \$200; 30 Shearling Rams, weighing from 230 to 285 lbs. each—Price from \$50 to \$100 each.

JOHN SNELL,  
Edmonton P.O., C. W.

Four miles from Brampton Station G.T.R.

**TO BE SOLD BY AUCTION,***On Thursday, Oct. 16, 1862,*

**T**HE well-known Herd of NORTH DEVON CATTLE, consisting of more than forty head of Cows, Bulls, and Heifers; one hundred and seventy West and Southdown Ewes and Rams; pure blooded Essex Pigs, in pairs fit for breeding.

Catalogues of description, with pedigrees, may be had fourteen days before the sale, on application at the office of the *Galt Reporter*, if by letter, prepaid. Credit of 12 months may be had on approved endorsed paper.

**THE SPLENDID FARM,**

Consisting of upwards of THREE HUNDRED ACRES, to be sold by private bargain, on accommodat- ing terms.

## Management of Dairy Stock.

Much of the profit of a dairy cow depends on a plentiful supply at all times of nutritious food. The variety in the quantity of milk they yield, is principally owing to the difference in the nutritive quality of the food they receive. Cows, it is well known, receiving food poor in alimental matter, fall away in milk. Add to the nutritive properties of their food, and they immediately increase their flow. The quantity of milk, then, does not depend on giving a particular kind of food, but on giving a quantity equal to the support of the natural waste of the body, and a remainder to be converted into milk. Farmers err very much when they undertake to keep more cattle than they have means to sustain in the best condition, especially in winter. The result is, their cows come out of the stable in the Spring weak and feeble, and struggle through half the summer before they are in a condition to yield milk in quantity more than equal to paying expenses. Dairy cows should at all times be in good condition. They should receive their food at regular intervals; their milk should be drawn at stated hours, and by quiet gentle milkers; and they should be treated at all times with the greatest kindness. In short every means in the power of the dairy farmer should be used to insure their tranquility.

Harsh treatment also exacts a very injurious action on the milk, rendering it less buttery, and more liable to acidity. Respiration is a

species of combustion. At every breath, we inhale oxygen of the atmosphere, which unites with and consumes the fatty matter of the food. When cows are worried or driven too rapidly, they breathe more frequently, inhale more oxygen, and more of the buttery portion of their food is consumed, leaving less to be converted into milk. Warmth is a substitute, to a certain extent, for food. Hence the importance, in cold weather, of tight building, avoiding cold draughts, with proper attention, however, to effective ventilation. Impure air acts as injuriously on the animal frame as impure or insufficient food. Cows, when warm and comfortable, will consume proportionately less food, and it is well known to all experienced dairymen, that their cows yield more milk in warm pleasant days, or when they have the run of warm well sheltered pasture, than on cold rainy days, or when they run in cold bleak pastures. When cold they inhale more oxygen; the result is a combustion of more of the carbon or oily part of the food, and less remains to supply the lacteal vessels with rich milk.

## Draining and Ashes.

EDITORS OF THE AGRICULTURIST, —In my former letter to you, which you noticed in the *Agriculturist* of the 1st inst., making inquiries respecting irrigation, where I said, "How near together should the drains be where I could not make them more than 16 or 18 inches deep?" You have mistaken my meaning, I ought to have

said underdrains. I had an idea that that part of the ground might be made dry by putting underdrains pretty near to each other, and thus compensate for the want of depth, and I wanted information as to how near they ought to be in order thus to compensate. Would it be any use attempting to underdrain it at all? It is nearly level and lies next the creek, and the flag limestone is very little higher than the bottom of the creek, so that there would be no chance of the water sinking down through any openings that might be in the rock. If the drains were made whenever there would be a flood in the creek the water would go up the drains. Most of the ground appears dry on the top, but it don't grow very much; it is in pasture: another part is in meadow, and lies a little higher, I am making a few underdrains in a part of it, but I cannot get them deeper than about 20 to 33 inches. I intend to try the water on it this Fall.

I am clearing a piece of new land for turnips, to be followed with spring wheat, and grass for the meadow or pasture till the stumps are rotten; is it better to sell the ashes, or spread them on the ground where they are, or rake them up to apply to old cleared land? If the latter be best, to what crops would it be best to apply them? and how,—mixed with other substances or by themselves? "Although the season is over for this year for sowing, yet your answers would be borne in mind by all interested in the subject.

I am, yours &c.,

J. W.

Cambray, 22nd Sept, 1862.

#### REMARKS.

Drains that for want of outfall cannot be made deeper than 16 or 18 inches will require to be near each other; say from 20 to 30 feet according to the nature of the soil and general character of the land. At the above depths drains would be liable to injury by ordinary cultivation, but if well made might be quite secure in pasture. Where stone is of easy access, five or six inches of broken stone placed immediately over the conduit of the drain will be found beneficial. We would suggest to our correspondent the desirableness of having a few surface drains at regular intervals in addition to the underdrains, so as to prevent the accumulation of surface water in spring, when the underdrains cannot fully act till the frost is sufficiently out of the ground.

With reference to the selling of ashes much of course depends on the price they will fetch. As a general rule we think farmers had better apply them to their older lands, which have been deprived by frequent cropping of the in-

gredients which wood ashes possess, and which are essential to the healthy growth and maturity of plants. Ashes may be beneficially sown broadcast on meadow or pasture, or mixed with the compost heap and applied to any of the cultivated crops of the farm. We shall be happy to hear from our correspondent again on the results of his irrigation.

#### The Field Bean and Rotation of Crops.

THE EDITORS OF THE AGRICULTURIST.—Can you favour me with some information about beans. If it be the case, as I am told, that the common bean does not pod in this Province, do you think any of those kinds that are largely imported into England from climates much better than Canada, such as Egypt, Sicily, Brazil, &c., would answer. By a short experience in farming I find I want a drill crop to found a rotation upon, and as turnips, except to a limited extent, are out of the question, I have thought if I could find a suitable bean it would come in as a substitute for a more eligible green crop. Indian corn has been suggested to me for the purpose instead, but from its requiring the same food as the other cereals, it appears to be objectionable. I do not see much said in the Journal about rotation of crops, a subject, judging from the little attention paid to it in general practice, might I think be profitably impressed upon the mind of the farmer.

I would like much to know from some of the more intelligent agriculturists of the Province what kind of rotation they find best, the subject is of so much consequence that a thorough discussion of it would prove highly instructive. A short experience tells me that our great want is manure, both in quantity and quality, and, in order to obviate the evil in some measure, recourse must be had to a scientific and judicious arrangement of the crops, and the application of what manure we have at the best time and in the most proper mode. This latter subject seems at present to be engaging much of the attention of the agricultural chemists in Europe, and as we in the wilds of Canada have not the advantages of reading the important articles which are appearing in the various agricultural journals of the three kingdoms, we must look to the contents of this journal and similar ones published on this continent for an account of the fast progress which is going on in agriculture in the old world, for there the greatest amount of mind is engaged and the most important results are effected.

"No. WEST."

October, 1862.

REMARKS.—The common field or horse bean, cannot, it would seem, be profitably cultivated

in Western Canada. It is raised, however, to some extent in the Lower Province, and also in Nova Scotia and Prince Edward Island, we believe, but with what success we do not know. We have tried, on a small scale, several varieties of the bean from different parts of Europe, including the southern portion, and also Egypt, but the results were not encouraging. Our soil, however, was too dry and sandy for the bean, which succeeds best in Europe, on heavy, moist land. In Canada our summer heat seems to come on too suddenly and intensely for this class of plants; the blossoms prematurely fall off, and consequently do not fructify. This is more or less the case with the broad or Windsor bean, cultivated in gardens, where, under the best advantages of soil and treatment, it is rarely a certain or productive crop. If any of our readers have had experience in the matters referred to by our correspondent we shall be happy to be made acquainted with the results. The question of Rotation is indeed of great importance, and we purpose hereafter to treat it with considerable fullness.

### New York State Agricultural Show.

The annual Exhibition of this important Society took place at Rochester the first week in October, and we are happy to say, considering the disadvantages of bad weather and the unsettled state of the country, was a decided success. A considerable number of Canadians was present, including Mr. Burnham, of Cobourg, the President elect of the Provincial Association, Mr. R. L. Denison, Treasurer, Hon. D. Christie, &c. We find that Mr. George Miller, and other Canadian breeders, carried off several first class prizes. The number of entries was somewhat below the average, but the quality of the stock, particularly sheep,—notwithstanding the absence of some of the best herds of the State, was decidedly good. The locality of Rochester is unquestionably among the very best for holding the State Fair. The *Rural New Yorker* thus sums up:—

The twenty second Annual Exhibition of the N. Y. State Agricultural Society was held during one of the most unpropitious weeks of the season—the morning of every day of the

Fair (and even of the day preceding its opening) being stormy or portentous of rain, just the weather or indication, to keep people at home. The sun was visible but a few hours from Monday morning until the close of the Fair on Friday, and more or less rain fell on every day of the exhibition. And yet the Fair was a grand success—an unparalleled triumph, in all respects, considering the unfavorable weather and condition of the country. The result is the more gratifying from the fact that many had predicted a failure, even with fair weather, and had seriously urged a postponement. Under the circumstances the Agricultural Society and People of the Empire State may well send cordial greeting to brother Producers and Unionists of the Loyal States, and also cite Secessionists everywhere to the result—as evidence that New York can not only do its full share towards suppressing the rebellion, but also exhibit undiminished zeal and energy in maintaining and advancing her Home Interests. Had the weather been favourable we doubt not the Fair would have proved the most successful, *in every respect*, ever held in the State—and that is equivalent to saying in the Union. The simple fact that the receipts were about \$11,000—some 3,000 more than last year—tells the whole story as to the location of the Fair and the effects of the war upon the material interests of the State."

In fruits and flowers this exhibition far exceeded any of its predecessors, arising no doubt from the peculiar advantages of the locality, and the great abundance of the season. The vegetable department appears to have been comparatively neglected, a serious imperfection, which our New York friends should, as they readily can, correct for the future. The arrangements for the fruit were somewhat novel, and appear to have been both convenient and attractive. We subjoin from the *Rural* a description:—

The fruits and flowers were exhibited in a fine oval tent, 85 feet in width by 110 in length. About twenty feet at one end was left for entrance and exit, and from this a table four and a half feet in width extended entirely around, making some 300 feet in length, containing about 1400 square feet, and this was devoted to fruit entirely. Fifteen feet inside of this was another table of the same width forming an oval, designed for flowers. This table was covered with moist sand four inches deep, and over this was placed sheets of moss, covering the whole surface. In this was placed cut flowers, so that there was no necessity for vials, which are constantly falling over, and are always a

great annoyance. Plants will keep well in sand and moss any reasonable time, and a slight sprinkling may be given if the weather should prove dry and warm. As guards around these tables a neat rustic fence was made of white cedar poles, with necessary gates for exhibitors, &c. This left a space in the center about forty by sixty feet, in which were the two masts or poles that sustained the top of the tent. These masts were covered with bark, so as to give them the appearance of trees, and pots of climbing plants in flower sunk at the base, while their branches extended nearly to the top. At the base of these poles octagon stands were made for the display of pot plants, covered with moss, and when filled with plants, produced a very fine effect. In the centre of the oval was a large bed of *Cannas* and *Celadiums*, and nothing in the whole exhibition was more admired than the splendid foliage of these plants. This bed was raised something like a fort, and surrounded with moss-covered rocks selected from the river bank. Scattered around where a few fine plants, such as the *Sago*, *Palm*, *Century Plant*, *Euphorbia*, &c., the pots and boxes concealed by rocks and moss. The turf was short and of good color, and the whole appearance was that of a fine lawn.

We are glad to learn that the able and courteous Secretary, B. P. Johnson, Esq., had returned from his visit and duties connected with the great International Exhibition in good health and spirits, full of hope and generous feelings both as regards the old world and the new. Although, as under the circumstances was to be expected, the amount of the United States contributions to that magnificent display of the world's art and industry, has been comparatively small, it must be gratifying to her enterprising and intelligent citizens that their importance and particular value have been appreciated in an unmistakeable manner. Let us hope, ere another New York State Show occurs, that swords will be transformed into ploughshares! We gladly make room for the following lecture and discussion in connection with the State Fair.

INSECTS INJURIOUS TO AGRICULTURE.—*The Grain Aphis, Wheat Midge &c.*

Dr. Asa Fitch, Entomologist of the State Agricultural Society, opened the discussion by reading the following Essay on the Grain Aphis.

Mr. Chairman and Gentlemen,—I am requested to preface the discussion, this even-

ing, by presenting to the audience some account of the Grain Aphis—an insect new to us in America, and which during the past and the present year, has been more prominent in the public regard than any other insect.

In the grain fields of Europe this grain aphis has existed from time immemorial. It was scientifically named and described eighty-one years ago, by the distinguished German entomologist, Fabricius, who met with it in fields of oats, and therefore named it the *Aphis Avenæ*, or the oat aphis, he being unaware that it occurred equally common upon other kinds of grain also.

But our European accounts of it are quite meager and imperfect. About all that we gather from them is, that it is an insect which shows itself upon the grain about the time of harvest, and that in some instances it has been known to be so multiplied, in particular places, as to literally swarm upon and cover the heads of the grain in many of the fields.

These few general facts, are all the information which the world has hitherto had of this insect. What becomes of it during the remainder of the year, where, and in what condition it lurks after harvest time, and until harvest time again approaches, had never been investigated. It was remaining for us in this country to trace out its abiding place and habits during the autumn, winter and spring, and thus complete its history the year round, as we have been able to do within the past eighteen months—under the instructions of this Society, and under the auspices of the State of New York.

In this country, this grain aphis has never been observed, and it was not known that we had such an insect here, until last year, when it suddenly appeared in excessive numbers over all the New England States, and the State of New York, except here in its western section, and also in the adjoining districts of Canada and of Pennsylvania. Throughout all this vast extent of country every grain field was invaded by it; many of these fields were thronged and a portion of them were literally covered and smothered by this insect.

This year it has moved westward, making its appearance in the same manner all over Western New York, Canada West, Northern Ohio, and at least a portion of Michigan, as I judge, from the numerous letters which have been sent me with grain-heads containing this insect, and from the notices of it in the public prints—whilst at the East, where it was so numerous last year, it has measurably disappeared this year, so that, except in a few localities, it would not have been noticed had not every body been so eagerly searching for it.

But though this insect has only been notice-

ed in this country the past and the present years, we do not suppose it has newly arrived upon this Continent. It has no doubt been present in our grain fields heretofore; but in such limited numbers, and so scattered about upon the growing grain, that it failed to be observed. It is seventeen years ago that I began to examine the wheat midge, and in looking at that and other insects upon the wheat, I recollect I have occasionally seen this aphid. But as only two or three individuals of this kind were to be found at a time, I supposed it to be of no importance, and thus gave no attention to it, until it began to appear in such abundance the past year.

Although it is a common habit of plant lice to become extremely numerous, at times, upon the particular kinds of vegetation which they respectively infest, we meet with no recorded instance in which one of these insects has been known to become so suddenly and excessively multiplied over such a vast extent of territory as has happened in our country with this grain aphid the past and present years.

I suppose almost every person in this audience has seen these insects, crowded together upon the heads of wheat, oats, barley or rye, and has observed that they are a kind of plant-louse, similar to what we frequently see upon the leaves of cabbages in our gardens, and on the apple, the cherry, and other trees. As it resembles these common and well-known insects so closely in its form, its motions, and habits, it will not be necessary for me to give any particular description of it.

With regard to the mode in which it injures the grain, I would observe that it has a slender, sharp-pointed bill or trunk, which it holds under its breast when this implement is not in use. With this it punctures the leaves and stalks of the grain and sucks their juices. It therefore has no occasion to leave the particular plant on which it is born, as it always has an ample store of nourishment directly under its feet. Hence, it has no use for wings to carry it, like other insects, from place to place in search of food. It needs wings for only one purpose, namely, to enable it to emigrate to fields of grain which are unoccupied, in order to start colonies in them. Only a small portion of these insects, therefore, acquire wings; and these fly away from the winter grain to plant their race upon the spring-sown wheat and oats.

The latter part of June, when the grain has advanced so that the heads or ears begin to put forth, two most remarkable changes occur in this insect, whereby it appears to become another creature, a different species, in the middle of summer from that which is seen in the spring and autumn.

One of these changes is in its habits. Be-

fore the heads appear, it lives singly, scattered about upon the leaves and stalks of the grain, and the young lice, as fast as they are born, leave their parents and wander away. But no sooner are the heads protruded from their sheaths preparatory to blooming and growing the kernels of the grain, than this aphid wholly forsakes all the other parts of the plant and becomes congregated upon the heads—evidently because the juices which the plant elaborates for the growth of its flowers and seeds are much more nutritious, more dainty and palatable to these insects, than are the juices which circulate in the leaves and stalks. They here fix themselves upon the base of the chaffs which envelope the kernels, and inserting their beaks, they suck out the juices which should go, first, to grow the flowers, and after that to fill and perfect the kernels. And now, the young lice which are born, instead of scattering themselves and travelling away, settle down closely around their parent, crowding as compactly together as they can stow themselves. Thus it comes to pass, that when these insects are numerous, as we have recently had them, in many of our grain fields, scarcely an ear can be found which has not a cluster of these lice around the base of almost every kernel, all with their tiny bills inserted therein, pumping out the juices which should go to swell and perfect the seed. Thus, this grain aphid from being a solitary insect, wandering about singly upon the leaves and stalks, becomes a gregarious insect, clustered together in flocks, and remaining fixed and stationary upon the lower or butt ends of the kernels.

At the same time, another change, equally remarkable, takes place in the color of these insects. So long as they nourish themselves on the course juices of the stalks and leaves, their bodies are all of a grass-green color. But when they come to feed on the more delicate juices of the flowers, they begin to bear young of an orange color. One of the grass-green insects having stationed herself at the base of a kernel, the next day, in the group of little ones around her, a yellow one will occur, all the others being green like their parent. A day or two later, as the nourishment she derived from the leaves becomes more dissipated from her body and replaced by that now obtained from the kernels, half the young she produces will be of this yellow color. And still later, all the young are yellow, no green ones being any longer born. And the older ones after a time dying and disappearing, all these insects some weeks before harvest time, become changed to a yellow color, their hue inclining more to red in some and to yellow in others.

It is truly curious that this green insect, thus, on coming to feed on the juices which

grow the flowers, begins to produce young of a gray yellow color similar to that of the flowers.

By depriving the kernels of a portion of the milky juice which should go to swell and mature them, this insect causes the ripened grain to be more or less shrunken and light of weight.

Rye, however, grows so rapidly and ripens so early, that it outstrips this aphid in its increase, and thus sustains no material injury from it. Winter wheat, ripening more slowly, experiences more injury. But the crops which ripen latest, and when this aphid has become multiplied to the greatest extent, namely, spring wheat and oats, become the most thronged and sustain the greatest injury.

Let us next inquire how it is that this insect is able to become so suddenly and so excessively multiplied as we have had it, in the Eastern part of our State last year, and here in its Western part this year.

I may observe that a hundred years ago it was a current opinion among men of science, that certain insects and other creatures pertaining to the lower orders of the animal kingdom were generated spontaneously. But, more recently, when these instances of supposed spontaneous generation came to be closely investigated, one after another of them were found not to be such. So that at this day the scientific world wholly discards the theory that there is or can be any such thing as spontaneous generation. All living things descend from parents; and it is by a pairing of the sexes that young are produced and that each species is continued in existence—some classes of animals bringing forth their young alive, others laying eggs from which their young hatch.

Insects are of this latter kind. They are all produced from eggs. But in the generation of the plant lice, we meet with one of the most remarkable anomalies which we anywhere find in the works of nature. These insects bring forth their young alive, at one time, and they lay eggs at another time. All the plant lice which we see upon our fruit trees during the summer are females, and these do not produce eggs, but living young, which mature in a few days, and (wonderful to tell!) they are fertile without any intercourse of the sexes. It is only when cold weather and frosty nights arrive, that males are produced. The insects then pair, and the females thereupon lay eggs. These eggs remain through the winter, to be hatched by the warmth of the following spring. The young from these eggs grow up and commence bearing living young, no males and no eggs being produced, except as the closing act of their operations in autumn.

Such are the general facts with regard to the generation of the insects of this aphid group. And I had supposed it would be the same with

this grain aphid. Some of you may have been present and heard the remarks which I made on this subject at our Fair at Watertown a year ago. I stated that the eggs of this insect would probably be found late in autumn, scattered about upon the leaves of the sowed wheat and rye—which eggs would hatch with the warmth of the following spring, to start the insect upon the grain again this year. But when frosty nights arrived last autumn, and when the aphid on the apple trees was found paired, and the females were busy depositing their eggs, to my surprise, nothing of this kind occurred with this aphid upon the grain. The mature lice continued to produce young ones, until they and their young became congealed upon the leaves of the young grain by the advancing cold of the season. And in this state they were buried beneath the snows of winter, and with the warmth of the ensuing spring they were thawed, and returned to life again.

To be better assured upon the subject, I placed some of these insects on grain growing in flower-pots and kept during the winter in a warm room. In this situation they continued alive and continued to bear young through the whole winter season.

Thus I have watched this grain aphid for a year round so closely, that I am perfectly assured no eggs were laid and no males were produced. Occasionally an individual was noticed, varying somewhat from the others, and which I have therefore suspected might be a male; but, on imprisoning such specimens in vials over night I have invariably found young lice with them next morning.

When, and under what circumstances males occur, is yet remaining to be discovered. At present it seems as though these insects might go on forever, producing young, without any intercourse of the sexes.

Finally, with regard to the fecundity of these insects, I would state that those which have no wings, and which remain on the stalks of grain on which they are born, are much more prolific than those which have wings and wander abroad. By enclosing them separately in vials, I found the winged females quite uniformly gave birth to two young lice in a single night, whilst the wingless ones produced four in the same time. We frequently see young lice produced in the day time, but fewer appear to be born then than during the night. The winged ones are also much slower in coming to maturity. I placed several young lice the morning after they were born upon some grain growing in a flower-pot, and on the third morning afterwards I found four little ones around each of them, showing that the wingless ones come to maturity in three days. It will thus be seen with what prodigious rapidity these creatures multiply. They almost double their numbers daily. A single one producing four young daily, and these becoming equally prolific when they are three days old,

her descendants in twenty days if all alive, will number upwards of two millions. This will serve to explain to us how it is that this insect becomes so excessively numerous upon the grain at harvest time as we have seen it.

As they multiply so rapidly, it is evident no vegetation which they infest would escape destruction from these plant lice, if nature had not herself provided most efficient means for checking and subduing them. We accordingly find that these insects are preyed upon and consumed by other insects, to a greater extent than are any other kinds of injurious insects wherewith we are molested. There are whole groups and tribes of predaceous insects which subsist exclusively upon the plant lice of different kinds.

A tribe of very small Ichneumon flies, named *Aphidius*, are parasitic destroyers of these insects—puncturing and thrusting an egg into the body of the aphid, from which hatches a minute worm which feeds within the aphid till it kills it. I have found two species of these parasites destroying the grain aphid.

Another most efficient destroyer is the Lady Bug or *Coccinella*, of which there are numerous species all of which are continually searching plant lice to feed upon, these being the sole nourishment of the lady bug, both in its larva and its perfect state.

In addition to these are the *Synphus* flies, the golden-eyed flies, and the laced-wing flies, all mortal enemies to the different kinds of Aphid.

By such means is it that these plant lice upon the grain as on other vegetation, are usually but a transitory evil—these their foes and destroyers, always gathering around them wherever they become numerous, and multiplying until they overbalance and subdue them.

Some one asked for a description of the Lady Bug. Dr. Fitch described it as follows:—It is about the size and shape of half of a small pea, of a yellowish red color, with round black spots upon it.

*Question.*—Is it poisonous to animals?

Dr. Fitch knew a single instance when swine had been pastured in a field where the lady bug was numerous. All of the herd were taken sick and some of them died. The swine were removed from the field to another, and such as were so removed recovered. Dr. F. said that it was possible that the swine were poisoned by large quantities of the lady bug; for if it is taken on the fingers and crushed, an acrid juice is emitted, which is doubtless poisonous, inasmuch as it is the insect's only means of defence. He had thought it possible that this particular herd of swine might have been poisoned by it.

*Question.*—Is there any prospect of the Aphid becoming a permanent pest in the country?

*Answer.*—I think not. Its enemies are too numerous for that. Not more than a single year at a time, will they be likely to ravage in

a single locality. As before said, they seem to be emigrating Westward.

*Question.*—Is the midge a permanent pest; is it plenty here at all seasons?

*Answer.*—There is no doubt that the midge is plenty in all parts of the country. The character of the season governs its ravages. If the latter part of June is wet, look out for the midge; if dry, there is no danger. In dry weather it cannot subsist on the uplands; it returns to the lowlands.

T. C. Peters—We are fast reaching the maximum of former years, in the amount of wheat sown in Western New York, and it is an important matter to us to know how to avoid the ravages of the midge. Do you recommend thorough culture?

Dr. Fitch—Strong growing wheat will produce despite the midge. Yes, I do recommend thorough culture as one of the preventives of the ravages of the midge; also of the Hessian fly and other insects.

*Question.*—What is the effect of the work of the Aphid upon the grain—upon the kernel?

*Answer.*—The insect extracts the juices from the plant, which aid in developing and maturing the kernel. This diminishes the size of the grain—sometimes virtually destroying it, for the substance is almost gone.

Mr. Geddes, of Onondaga, does not agree with Dr. Fitch concerning his theory, with reference to the existence of the midge. He doubts if the midge exist in as great numbers one year as another, or if they are present at all; for prior to the last six years he had failed to get a crop of wheat for some years on their account; while the past six years he had grown it successfully. His success, he thinks, is not due to dry June, but to the fact that the midge had disappeared. He doubts, too, if his success is due to superior culture; for he used to summer fallow all his land; now he turns it over and seeds after barley, and oats &c. &c.

T. C. Peters—So far as white wheat is concerned, the theory of the effect of the season upon the ravages of the midge upon it, is correct. But the Mediterranean is the only variety that can be grown now safely. He thinks the white wheat has very much degenerated.

Other gentlemen present coincided with him in this matter and united in asserting that the best mode of redeeming white wheat was to change the seed. It was further agreed that the Mediterranean had greatly improved by cultivation—that it was "bleaching out."

Mr. Bishop, of Wyoming, asked if early or late sowing had not had to do with checking the ravages of the Aphid?

Dr. Fitch replied, yes. Its ravages are greatest on the late sown wheat. Late sowing is not advised, if the object is to avoid its ravages. The same remark applies conversely to the midge. It does not so seriously affect the late, as the early sown wheat.

Pres't Cornell—Have you observed the Ap his in the ground around the roots of the barley?

Dr. F. had so discovered it.

Mr. Geddes—Why is it that the midge should have appeared one year, and not doubled the second and tripled the third, &c., &c. He thought the midge was disappearing.

Dr. Fitch said there were two successive years when the midge disappeared, and then the third year appeared again, and was very destructive. He does not think it was because the midge passed away from the country, but because the season was not favorable to its development—or at least not favorable to its operations on wheat—it passed to some other grain.

At this point there was a rambling conversational discussion upon the relative value of different varieties of wheat. Much of this the reporter was unable to hear. But he heard enough to establish the fact that there were many present who believed the Mediterranean the safest and best wheat to sow; that it was improving in character, while the white wheat of the Genesee Valley was deteriorating. A few claimed that better flour could be made from the Mediterranean than from any other wheat.

### Fat versus Lean; or the Obese System of Feeding Cattle.

In this article we propose offering a few desultory observations on the question, Has the obese system of fattening cattle, as practiced for upwards of half a century, and which is still the fashion, a tendency to increase the normal proportions of fat, but decrease that of lean, and without increasing the carcase-weight of animals? Speaking from memory, the object of the Smithfield Cattle Club is *'To produce the greatest possible amount of meat of the best quality at the lowest price.'* Such being their proposition, the remarks we are about to make will show, that by encouraging the production of an excess of fat, the greater portion of which goes to the tallow-chandler, the lean meat, available for the food of man, has been decreased below the normal standard, both as to weight and quality. And if we shall succeed in proving this, the reader will readily perceive that the Smithfield Cattle Club are not performing the functions for which they were constituted. The Royal Agricultural Society of England, the Highland Society, and the other societies, both for breeding and fat stock, are in a similar position, the general practice pursued having a tendency to increase fat, but decrease the weight and quality of lean.

It may be as well in this place to mention, that our object is to induce the Smithfield Club, and other fat-stock Clubs and Societies, to take the necessary practical steps for encouraging the opposite practice, viz., the growth of rich juicy lean meat in greater abundance, with no

more fat than is necessary for health and domestic economy. In other words, *LEAN versus FAT; or the natural system of feeding cattle.* But to the solution of this latter problem we shall have to return in a subsequent article. For the present we have enough on hand to dispose of the opposite problem at the head of our paper, viz., *FAT versus LEAN; or the OBESE SYSTEM OF FEEDING CATTLE.*

*What is fat?* The printer has one answer to this interrogatory and the farmer has another; but we shall have to take up the question in a somewhat different light from either, with a view to determine the function fat performs in the animal economy, and the purpose it serves in the dietary of man and cattle.

Although considerable attention has already been paid to the chemistry of animal fats, as of the ox, sheep, and pig, yet much remains to be done to supply the growing demands of physiology. These fats are regarded as having a true saline composition, consisting of stearic, margeric, and oleic acids, and a common base glycerine, thus forming stearine, margarine, and oleine. But it is a well-known fact, that each of the above fats, viz., ox-fat, mutton-suet, and hog's-lard, is associated with other proximate principles, and that a knowledge of these would be of more importance to the physiologist and farmer, and also to the physician, than a knowledge of those usually specified by chemists. Thus "mutton-suet consists of stearine, margarine, oleine, hircine, and hircic acid" (Reveira,) and most probably other flavouring matters than the latter two, as the taste of the suet is always more or less affected by the quality of the food on which the sheep had been fed. Thus the suet of the sheep fed on rich down or hill pasture is finely flavoured, while that fed on oil-cake is the reverse. Similar diversities in the quality of food produce corresponding effects upon the taste and flavour of ox fat and hog's-lard.

"The fat, considered physiologically," says Dewglison, "has for its function to protect the organs, maintain their temperature, and to serve for nutrition in case of need, as is observed in torpid animals." According to this writer, its functions is thus of a threefold character. In a normal state of health and weight, for example—first, so much fat is necessary to protect the organs; and, secondly, so much is required to keep up the temperature of the body.—For both these purposes a daily consumption of fatty matter may take place, and such will be procured directly from the food if it contains so much. But, in the third place, when the food contains more fat-forming elements than are required for the above two purposes, a reserve of fat is stored up in the adipose tissue to supply the demands of the system in the emergency of none being obtained from food, as in the case of hibernation, when animals sleep during winter in a torpid state; or

in the case of fasting during seasons of scarcity, as in winter in this country, and in periods of drought experienced by the fat-tailed sheep and humped-ox of East Africa, where we see nature making ample provision for peculiar exigencies of this kind.

In the case of fat-tailed sheep and hibernating animals, the accumulation of fat is natural; so that the normal health is not injuriously interfered with. But the reader must be well aware that unnatural practices are resorted to, in order to produce an accumulation of fat in our domesticated animals—as in the cramming of geese, blinding quadrupeds, &c., &c., when an abnormal state of health is experienced in various forms; as, for example, of obesity, rot, &c., &c., &c. It is to the principles involved in the abnormal cases that our observations will be chiefly confined, viz., to an excess of unhealthy fat, a decrease of lean, and an excess of water and bad fat, as in the fatty stage of sheep rot, &c., &c.

In the process of fattening geese (to obtain the *foie gras* of the French) by cramming with fatty food, in that of fattening women for harems in Turkey on *flour and honey*, in sewing up the eyes of the cattle in the East, or in fattening them in dark warm places and on improper food in this country, similar principles are involved. Sleep, or a state of the system similar to it, for instance, is induced. The number of respirations in a given time is thus lowered, and consequently the consumption of fat-forming element. The active functions thus concentrate their energies, as it were, almost wholly to the formation of fat of an inferior quality. And as the rule holds good in this as in all other mechanical questions, it consequently follows that nervous and muscular action cannot take place but at the expense of matter. Now, in the case before us, the expense of matter is reduced to its natural minimum; thus leaving a much greater surplus than in ordinary cases to be stored up in the adipose tissue. And more than even this surplus goes to increase the weight of the carcase; for in cases of obesity the excretory functions seldom remove the whole of the refuse of the system that does take place; so that this has also to be added to the coarse fat, to swell the total weight of inferior meat sent to the shambles.

In the forcing system of oilcake-feeding cattle for the shambles now generally pursued, the above principles are carried out, although not perhaps to the same extent as in cramming geese or in fattening some special animals for Christmas fat-stock shows. In the former case, however, the principle is as objectionable as in the latter, for a very large proportion of the heavy meat about this season is by far too fat, even after the butcher has pared off tubfuls of rough fat for the tallow-chandler; while the fat that goes with the lean is of a very inferior quality, being often unfit for human food. Turcips and

oilcake are not the natural feeding materials of our cattle; and when animals are allowed, and even induced to eat large allowances of either, the appetite being depraved or voracious, but especially of the latter, oilcake for oxen and sheep, and barley-meal for pigs, &c., &c., under confinement, and with a limited amount of light and fresh air, sleep is induced; while the same abstraction of certain functions, and contraction of others, take place, in order to liberate the blood of fat-forming element, and to deposit it in layers and patches separately from the lean, as in the case of geese, Turkish women, or other examples of obesity. In the case of breeding stock it is much worse than this, obesity having a stronger tendency to become hereditary in the breed. So that the obese system as exhibited at and encouraged by the summer meetings of the Royal Agricultural Society is tenfold more objectionable than it is at our Christmas fat-stock shows; for when obesity becomes hereditary in breeding stock, it is hardly possible to prevent even milch cows from becoming too fat when full fed, while if they or their offspring are stinted in their daily allowance, skin and lung diseases are the inevitable results.

This extra-fat system is, in the second place, diametrically opposed to the growth of lean meat. The sleepy dulness and peculiar state of the nervous system generally attending the deposition of extra quantities of fat under obesity, in any of its stages, not only prevents the development of muscle or lean meat, but even has a tendency to produce atrophy, or wasting of the lean. Indeed it always does so, when animals are allowed to lie too much with overloaded stomachs. And such is the extent of atrophy produced in some animals that, when they continue to lie upon one side for a length of time they frequently become unable to rise and stand upon their feet. The details of the physiological *rationale* of this we must postpone to another article. At present it will be sufficient if we merely mention that this waste indirectly arises from the want of the necessary amount of exercise, light, and pure air, with a proper supply of natural food to maintain the equilibrium of live muscle. The lean of meat undergoes changes in the animal economy, to which the fat is not subject. The latter is deposited in small vesicles, or sacs, there to remain in store until required for use when the supplies from without (in the food) begin to fail; but the former is subject to a continuous pulling-down and building-up, or reparative, process; and unless both these processes take place in a proper manner, the healthy development of lean meat cannot take place. The blood, (both venous and arterial), lymph, and juice of the flesh must also be in a normal state of richness and purity. Now in the case of obesity under this example, where the excess of water is removed from the system, in contradistinction to

the next, or third, example, where an excess of water, along with an excess of fat, is formed, the above conditions necessary to the healthy development of lean meat are not present, but the contrary; for the blood, lymph, juice of the flesh, and the pulling-down and building-up process of the tissues, are all in an abnormal state, being more favourable to atrophy than to growth of tissue and the filling up the flesh with rich juice. Under such circumstances, it is not, therefore, surprising that extra-fat animals are devoid of muscular energy, and unable to endure fatigue; for all those muscles engaged in their locomotion are reduced in tone and strength to what they were at a previous period, when carrying less superfluous fat. The extra weight of fat is sometimes erroneously said to be the cause of this muscular debility; and no doubt, to a certain extent it is so, while it at the same time unfits animals from walking long distances, owing to the manner in which it affects respiration. But this is not the real cause, for the heaviest animal does not always experience the greatest amount of muscular debility. On the contrary, it will be found, when practically examined, that muscles have actually lost volume and contractile force, being thus less able to perform their respective functions.

In the third example, water accumulates in the system as well as fat. The fatty period of sheep-rot is a familiar instance of this kind; but an extreme one. Amongst the extra fat stock exhibited at our fat shows, and also at our weekly markets, there are numerous examples of this kind. The colour of the meat depends something upon how the animal "dies," technically speaking; but generally it has a florid red and watery appearance. The percentage of water may not perhaps much exceed what was found in the lean of beef, by Brande 74, Schlossberger and Berzelius 77; in mutton 71, by Brande. But the juice of the flesh is thin, being deficient of osmazome, albumen, and other elements, that give it consistency and richness of flavour; consequently, although it may be tender, it is soft, watery, and insipid, requiring lots of artificial sauce and condiments to season it in the cooking and eating. The blood and lymph are in a similar state of tenuity. When the several fluids lose their normal state of equilibrium, endosmoses and exosmoses take place, as seen in the advanced stages of sheep-rot.

This abnormal condition is evidently a species of disease, and when animals labour under it, they have a very dull and languid appearance, while their meat is very unwholesome, and unfit to be used as food. Obese barley-meal fed pork may be white, and so may the fat of the ox and sheep; but this is only an evidence of its unwholesome character, for meat deprived of its colouring matter is indigestible.

We have thus arrived at not a very favourable conclusion relative to the quality of the

extra fat meat now exhibited at our Christmas fat stock shows, and of the breeding stock exhibited at our summer meetings. In short, the forcing system of feeding cattle is objectionable. Had the animals shown in Baker Street, for example, at Christmas, 1861, been slaughtered on the spot, and their carcasses exhibited, as they generally have by this time been by the butchers who bought them, would not the exhibitors have been ashamed of the quality of the meat? And would not the vast concourse of visitors have turned up their noses at the smell, and ridiculed the very idea of using for twelve months consecutively no other quality of animal food? And, if an affirmative answer must be given to questions so plain, the conclusion, as to the general principles which such a practice of fattening and breeding stock involves, need not be repeated in this place. Many important advances have been made in every branch of applied Science since our Agricultural Societies and Clubs first entered upon the discharge of their respective functions, and we hope they will, during the current season enter upon one of international significance with an honourable sense of the fresh duties which the progress of things thus calls upon them to perform. During the past half century we have learned to grow fat in overflowing abundance; but, unfortunately at a very heavy sacrifice of lean meat, and even of the quality of the fat itself. This reduction in the growth of lean has, of course, greatly increased the proportion of fat; for, had the growth of the former kept pace with that of the latter, then there would have been but small reason for complaint. And, besides this, a great waste of the most valuable elements of food takes place under the obese system of feeding cattle; but to this we must return.—*Farmer's Magazine.* W. B.

### Directions for the Cultivation of Flax.

The Jacques Cartier Agricultural Society of Canada East, have issued the following directions for the cultivation of flax:—

*Soil.*—The best land for flax is a dark coloured loam with a clay subsoil: it will grow on almost any soil, but such as contain a large portion of vegetable matter in their composition are undoubtedly the most proper for flax; but whatever be the kind of soil, it ought to be in neither too poor nor too rich, but what is called in good condition.

*The place of flax in the rotation of crops.* If the crop is to be allowed to ripen its seed, it should be considered as a grain or exhausting crop, and as a green crop when the plant is pulled green: if intended to ripen its seed it should follow potatoes, turnips, or some other green crop; if to be pulled green, it should then be sown upon land from which one crop of grain only has been taken after

having been several years in pasture; in either case this will cause no derangement on a farm where a six or seven years' rotation is practised in the first case, grass seed should be sown with the flax and in the second should take the place of a green crop, and may be followed by barley or wheat, if allowed a slight dressing or manure after removing the flax.

**Preparation of the Soil.**—In all cases the land should be deeply ploughed in autumn into ridges ten or twelve feet wide, well water-furrowed; this done in the proper season, in a proper manner, the frost of the winter will put the land in a finer state of pulverization than any other implement man can employ; the land should be well harrowed before the seed is sown, then cover the seed by passing the harrow a couple of times over it, water-furrow the land, and remove all stones which remain on the surface; this finishes the seed process.

**Time of Sowing.**—From the 10th to the 20th of May is the best time in this locality; if sown earlier, the seeds of annual weeds will spring up with the flax, and will either injure the crop, or cause more labour in weeding it, whereas if sown about the middle of May, a great number of the seeds of weeds will have already germinated, which the process of weeding will kill, and consequently save labour in weeding.

**The Quantity of Seed.**—This will depend upon the intention of the crop; when a crop of seed is intended to be taken, thin sowing is preferable, but it is a mistake to sow thin when flax is to be taken for the crop; it will grow coarse and less productive; from a bushel and a half to a bushel and three quarters should be sown per acre.

**The Choice of Seed.**—It should be weighty, of a bright brownish colour, and slippery to the feel in putting the hand among the seed.

**The Manner of Sowing.**—It is always sown broadcast, but if seed is the main object, drilling may be adopted.

**After Culture.**—This consists chiefly in weeding, but sometimes should commence with rolling the surface when the soil is very dry, the season advanced, or the earth very light and porous. The weeding, if required, should be done when the crop is about four or five inches high; there is no danger of injuring the plants by walking over them to pull out any weed that may have grown up with them, or even by turning a flock of sheep amongst it, as the sheep will not taste the young flax plants, and a fine dewy night will put all wrongs right; the rest, until harvest, is in the hand of a beneficent Providence, who alone can bring to a successful issue the work of our hands.

**Harvesting the Crop.**—The flax crop is taken by pulling; this should never be done

before it comes into flower, when fibre is the sole object; or before seed in the pod acquires a brownish colour, when fibre and seed jointly are required.

**Rippling.**—This is the next operation, and may be quickly done by presenting the seed end of the flax to the cylinder of a threshing mill, withdrawing the stalks, and binding them in bundles for the purpose of steeping. The best water for steeping flax, is clear, soft, and in standing pools; the time it should remain in the water will depend upon the nature and temperature of it; the most certain rule by which to judge when flax is sufficiently watered is when the reed becomes brittle, and the bark separates easily from it; it must then be taken out of the water and spread very thinly on the ground in regular rows; when it has become perfectly dry, it may then be bound up in bundles and either carried to the scutching mill, or stored away under cover, where it may remain for years without injury to the fibre, if kept dry. The other processes to which flax is subjected before it is converted into thread or linen, belong rather to the manufacturer than to the farmer.

### Short-Horn Breeding.

We have frequently in these notes had occasion to speak of the principle of selection exhibited in mixed blood, or in other words, the combination of good families of all sorts, as lying at the very root of sound breeding, and as being its real purpose; we have also stated, as a fact at once arising out of this fundamental law and proving, that what is expressively denominated "distinct blood," of which the short-horns of Bates and Booth are signal but not exclusive examples, is the result of persevering selection, which ever has been and ever will be associated with the cultivation of the finest animals. "Distinct blood" is selected blood which has become distinguished in the hands of certain successful breeders. "Anybody" (as it was observed in these columns a few weeks ago) "may be a follower of a distinguished breeder; but to be a successful imitator of him not only implies a recognition of the great principle of selection by which all eminent breeders have invariably shaped their course, but involves the necessity of occasionally deviating from the most satisfactory practices; just as they deviated; in order either to maintain what has been accomplished, or to accomplish and secure something still better. It is thus that our leading short-horn breeders, without exception, acted, in their best days. Careful selections and thoughtful combinations of materials that seemed worthy, whatever their source, preceded success, and were among the chief conditions of it." The history of Killerby and Warlaby confirms the general practice. We propose, on the pre-

sent occasion, to trace that history, with as much particularity and attention as time and space will permit, with reference to selection as the chief means of attaining excellence; and shall avail ourselves of an early opportunity to enter upon a similar engagement with respect to the blood of the Kirklevington short-horns. Neither Mr. John nor Mr. Richard Booth achieved renown by ways that are inaccessible to other breeders, nor did either of them achieve renown by methods that are not deserving of universal imitation. The servile submission of will and judgment of the authority of a name and the imperious demand of fashion, by which the fitful and frivolous career of some of their admirers has been more or less characterised, is not to be charged against them. They adopted the labors of predecessors and contemporaries, cheerfully and freely; but they adopted them at the same time deliberately and independently, using them, not as denoting finality, but as conducing instrumentally to unattained results. They were no snappers up of unconsidered animals. The bait of a pedigree *et prater ea nihil* failed to catch them. Something more than other men's leavings, or the sweepings of weeded herds, was demanded by these august exemplars of a noble science. They looked before and after; they examined, considered, compared, *selected*; and their careful and patient operations issued in effects which have been long before us, stamped with the approbation not of a nation only, but of the world. In prosecuting our proposed inquiry we assume at the outset that the Warlabby and Killerby blood is properly designated *now* by the term "distinct;" the main question to which we invite the attention of the reader being, not so much the character of Booth blood, which we are glad to admit is as fine as blood well can be, but in what way this blood arrived at its present state.

So far back as about the year 1810, upwards of fifty years ago, we find Mr. Thomas Booth, the father of the late John Booth, of Killerby, and Mr. Richard Booth, of Warlabby, using, in addition to his own bulls, sires from the Collings, Charles and Robert; and among the *principal bulls used as crosses within the last fifty-two years, but not bred by the Booths* (that is, by Mr. Thos. Booth, the father, or Messrs. John and Richard Booth, the sons), are Albion (14), bred by Mr. C. Colling; Pilot (496), bred by Mr. R. Colling; Rubens (5027), bred by Mr. J. Colling, White House; Remus (550), bred by Mr. Wright; Stephen (1456), bred by Mr. Charge; Matchem (2281), bred by Mr. Mason; Lord Lieutenant (4260), bred by Mr. Raine; Mussulman (4525), bred by Col. Cradock, and afterwards the property of Mr. Lax; Lord Stanley (4269), bred by Lord Carlisle; Exquisite (8048), bred by Earl Speer; and Water King (11,024), bred by Mr. Torr. Among the bulls which cannot with propriety be called principal bulls, but we abundantly used, though not bred by

the Booths, are sir Alexander (591), bred by Mr. J. C. Maynard; Scipio (1421), bred by Mr. Donkin; Ambo (1636), breeder's name not recorded, but his dam was bred by Mr. Poole; Francisco (2032) and Velocipede (5552), bred by Mr. J. C. Maynard; and Burley (766), bred by the same gentlemen, and out of and by a son of Venilia by Mr. Bates's Enchanter.

These details are far from being supplied in a spirit at all depreciatory of the Messrs. Booth. On the contrary, they are offered as affording very strong proofs of their sagacity and wisdom, and as a precedent which cannot be followed without immense advantage to all who adopt it. We have omitted several bulls intentionally, and some are, no doubt, omitted inadvertently; but this list, defective as it is, is sufficiently complete to assure the reader that the practice of the Booths convincingly illustrates the principle of selection, and establishes the general propositions we have advanced in its favour. It does not, of course, follow from the fact of so many *bulls* from various quarters having been used that a great variety of *blood* has been related by affinities more or less near; but a somewhat cruel examination of the composition of the pedigrees of the bulls whose services were engaged at Killerby and Warlabby shows that such was not the case, and that not only were many bulls used, but much blood of a diversified character was sought and adopted. We do not ask which of these crosses the Messrs. Booth liked best, or whether they ever regretted having adopted any of them: our present business being chiefly to set before the reader some evidence bearing upon the allegation, that the Booths, in attaining reputation, in no wise discarded the principle and practice of mixing blood from different sources and of different strains. More recently, the principle upon which Mr. Booth has proceeded, in resorting to a new cross, has evidently been to adopt a cross nearly allied to his own blood, thus avoiding abruptness of transition whilst he obtained the impulse of a fresh element. In two of the latest of the Warlabby crosses with other blood, the Water King and Lord Stanley crosses, this is strikingly apparent. Water King was out of a pure Bates cow, and by Baron Warlabby, a pure Booth bull; and the granddam of Lord Stanley was Lady Sarab, bred by Mr. Richard Booth, and own sister to Isabella by Pilot.

So far, then, from the Booths forming any exception to the principle of *selection* they are very prominent examples of it, and we may add, of its beneficial tendencies. It was during the time when this principle most largely prevailed with them their best families were consolidated. The partial reader may acknowledge the general truth of our observations, but may meet them by alleging that Mr. Booth's short-horns being now perfect, the necessity for occasionally re-

sorting to other blood is removed. We should dispute, upon physiological data, the inference thus imagined; for we believe the conclusion which cannot fail to be deduced from such data is altogether in an opposite direction, and enforces most distinctly the indispensability of forming new alliances in blood, if the health and strength and *fertility* of the old stock is to be perpetuated. Excessive in-and-in breeding obtains almost unavoidably in the early stages of the improvement of a species, and contributes greatly to the *speedy* attainment of that purpose, by condensing and intensifying in one animal properties that are desirable; but it by no means follows that what answered at one end of a process will answer equally well at the other; and we believe the concurrent testimony of the chief physiologists is hostile to the practice. Since Mr. Richard Booth has succeeded in letting his bulls for great prices, and the discriminative expression "Booth blood" has come to be affixed to the blood of the Warlaby animals, the habit of drawing upon other herds for new crosses has been discontinued, and the Warlaby herd is maintained entirely by sires bred upon the premises. Mr. Booth still adopts the system of selection, but not in the same way in which he adopted it when engaged in building up his reputation. His selections are no longer from the herds of other breeders, but from his own. He selects, apparently with thought and care, from his numerous bulls those which may seem to him best calculated to propagate the characteristic qualities of this far-famed short-horns; but it is said to be evident to almost everybody who considers the subject, not excluding the warmest admirers of Warlaby blood, that a policy of this sort contains within it the seeds of self-destruction; that it is merely a question of time; that it is the beginning of the end; and that, sooner or later the end will come. Such a result must be held to be *inevitable*, if it is according to the laws of nature that a persevering adherence to the same strain of blood without interruption impairs the energy and power which are absolutely indispensable to *perpetuate with regularity an improved species*.—*Bell's Messenger*.

### Steam Cultivation at Woolston.

On Friday last we paid our annual visit to Woolston, to see the results of steam cultivation, and to mark its progress in that chosen spot of its inauguration. Like all true pilgrims to the object of our study, we are happy to record that cultivation by steam is not only a grand recognized fact in that now renowned locality, but that it is gradually extending itself into a wider area, and is promising to become as general as horse and hand power in the tillage of the soil. We find, in short, that steam is no longer an

auxiliary to horse culture, but that horses are the auxiliary to that power. To show this we will just take a glance at the Woolston Farm.

In unison with our usual details of this highly interesting farm, we will take the heavy land first. Field number 1—wheat stubble: The corn was just cleared away: the stubble was remarkably clean, and by its strength showed that the crop must have been very good. It is also right to state that this wheat had been sown broadcast, therefore it had never been hoed, nor any other costly operation bestowed upon it to have produced the cleanly appearance which it presented. This field of stubble is sown with clover, and will require no operation this autumn. Field number 2 is beans, which is a fine, strong, and full-corned crop, and is estimated by Mr. Smith to produce forty-five bushels per acre. The men were cutting the beans, which enabled us to see the remarkably clean state the land was in. This will enable Mr. Smith to use his combined machine to cultivate and drill in the wheat at one operation. No horse labour will, therefore, be required here. Number 3 field is swedes—half a crop, the flies having destroyed the other half.—They have been horse-hoed four times, giving six days' employment to three horses. The land is clean, and will require no operation until the turnips are eaten off, and it is time to plant the barley in the spring. Field number 4 is barley, being cut; had been harrowed three times, giving two days' employment for horses; it is a fine, strong-strawed, and long-eared crop, and will produce, according to Mr. Smith's estimate, seven quarters per acre. This land, after the barley is carted, will be smashed up by steam, and cross-cultivated with horses, giving the three horses only two days' work.

We next come to the light land. Field number 1 is a fine healthy crop of beans, the stalks being from six to seven feet in height, and well corned. The produce from this field is estimated at not less than sixty bushels per acre. On looking under the beans we could quickly see that the land was perfectly clean, and that the combined machine could be easily used, cultivating the land and drilling the wheat at one operation; therefore, no horse labour would be required here. Number 2 is in roots—swedes and mangels. The latter is an average crop, Mr. Smith having had to sow his swedes a second time, the fly destroying the first plant. The roots have been horse-hoed four times, giving six days' employment to his horses during summer.—Number 3 was part oats and part wheat, both being carted; the oats were a fine crop, harrowed three times, giving one day's work for the three horses, and yielding at least ten

quarters per acre; and the wheat was an average crop, the wire worm having damaged a portion of it. The stubbles are very clean. One smashing and one cross cultivating, with the ridging and subsoiling, will be enough for the next root crop. Here we get two days' work with cross cultivating, four days' work with ridging, and four days' with subsoiling. Number 4 field is wheat stubble—very strong in the straw, and the crops taken from it will produce 50 bushels per acre.—The stubble is very clean, and when cleared off will be smashed up by steam and cross cultivated with horses, ready for beans in the spring. This will give two days' work to the horses. Number 5 field is a clover lea fed off; will be ploughed with horses for wheat, and will give 12 days' work for three horses. Number 6 field is barley; has been harrowed three times, giving two days' employment to three horses, the men cutting it. It is a very strong crop, the sheaves, where cut, lying thickly on the ground, and promises, according to Mr. Smith's estimate, a produce of 70 bushels per acre. There is a very good plant of clover upon it, and, therefore, it will require no operation this autumn.

In conclusion, we can state that the horse labour on the farm has been till the present time as follows: On number 3, heavy land, six days; on number 4, heavy land, two days; on number 2, light land, six days; on number 3, light land, one day; and on number 6, light land, two days. The work to be done this autumn will be—On number 4, heavy land, two days; on number 3, light land, ten days; on number 4, light land, 2 days; and on number 5, light land, twelve days, giving a total for the year, 43 days, with these horses, on the Woolston Farm. Here we have steam versus horse power demonstrated in the culture of our heavy clay soils.—*Bell's Messenger*.

### On the Feeding Value of Straw.

The wet weather which prevailed during the greater portion of the late hay-making season has, we fear, in many places greatly deteriorated that crop. In a recent ramble through the counties of Kildare, Carlow, and Wicklow, we saw but too plainly the ravages which the humid element had made on hundreds of portly cocks of hay. We were present at the sale by auction of the produce of a meadow of eight acres, which realized little more than 1s. 3d. per cwt. This is by no means a solitary example, as we have been informed by several auctioneers that large quantities of inferior hay have been disposed of this season at exceedingly low prices.

Very inferior hay is generally purchased by the hay dealers, and is mixed by them with a good article; and so skilfully, too, that the

mixture of the good and bad is often sold at the price commanded by the good, when disposed of *per se*.

We are clearly of opinion that inferior, fibrous washed-out hay is dear almost at any price, and that the money paid for such an article would be much better expended if invested in oats and straw.

Very discrepant indeed are the opinions relative to the nutritive and the fertilizing value of straw. In Germany and many parts of Britain it is held in such high estimation as a manure that its sale is strictly prohibited in most leases. In our own country many farmers believe it to be almost valueless as a feeding substance, whilst others entertain a high opinion of its alimental value.

The result of the experiments of Lawes and Horsfall prove that straw chaff is, as an adjunctive article of food, deserving of the farmer's attention. We think, too, they demonstrate very clearly the wastefulness of practice which prevails on so many farms of converting all the straw into litter, solely for the purpose of increasing the manure heap.

That straw, in a chopped, or what is still better, thoroughly bruised state, is a most useful feeding substance, the result of its chemical examination, and of actual feeding experiments with it, place beyond doubt; and as its price is comparatively low, it will be found a more economical feeding stuff than the wash-out coarse hay to which we have referred.

The analyses of hay which from time to time are published, exhibit every thing but uniformity. This arises from the complex and unconstant nature of the article, which, as is well known, is a variable mixture of various grasses and clovers.

Good hay, carefully saved, has, on an average the following composition:—

|                               |       |
|-------------------------------|-------|
| Water .....                   | 15    |
| Flesh-forming substances..... | 8     |
| Fat forming matters.....      | 44    |
| Woody fibre.....              | 27    |
| Ash (mineral matter).....     | 6     |
|                               | <hr/> |
|                               | 100   |

Coarse hay, which had been subjected to the influence of heavy and constantly recurring rain, will probably have the following composition:

|                               |       |
|-------------------------------|-------|
| Water .....                   | 14    |
| Flesh-forming substances..... | 4     |
| Fat-forming substances.....   | 37    |
| Woody fibre .....             | 40    |
| Ash .....                     | 5     |
|                               | <hr/> |
|                               | 100   |

The following table, compiled by Voelcksy, exhibits the composition of the straw of the cereals; and by comparing the analyses set forth in it, with those above given, a tolerable accurate estimate, for practical purposes, of the

relative value of both classes of feeding substances may be realized.

|                    | Wheat<br>Straw. | Rye<br>Straw. | Barley<br>Straw. | Oat<br>Straw. |
|--------------------|-----------------|---------------|------------------|---------------|
| Water.....         | 14.23           | 14.30         | 14.30            | 12.06         |
| Flesh-formers .... | 1.79            | 2.29          | 1.68             | 1.63          |
| Fat-formers.....   | 31.06           | 31.15         | 39.98            | 37.86         |
| Woody fibre.....   | 45.45           | 43.18         | 39.80            | 43.60         |
| Ash. ....          | 7.37            | 3.08          | 4.24             | 4.85          |

100.00 100.00 100.00 100.00

From these tables it will be seen that the only very important difference between hay and straw, is the high percentage of flesh-forming substances in the former. But it should be borne in mind, when comparing the relative value of the two articles, that the amount of flesh formers in a substance is no longer taken as the absolute criterion of its nutritive value. There is good reason to lead us to assume that all the fat-forming substances in the oil-cake given to animals are assimilated, whilst a large proportion of the nitrogenous or flesh-forming substances pass through the animal's body unaltered. This fact—for so we believe we may term it—is of importance to farmers who use their straw chiefly for cattle. The straw is sufficient in flesh-forming matters and abounds in fat-forming elements. In all oil-cake there is an excess of the flesh-forming substances. It is clear, then, that by a mixture of the two articles the “happy mean” would be attained.

Many of the best feeders in England employ large quantities of straw as food. It is stated that some of them adopt a peculiar and secret mode of preparing the substance, whereby its value is greatly enhanced. If we might venture an opinion on the subject, we would say that the “secret” consists in using only good straw, chopping it finely, and adding it in proper proportion to the other articles of the animal's diet.

As straw includes a considerable proportion of woody fibre, which is hardly if at all digestible, its mechanical preparation is a point of great importance. By chopping finely or thoroughly bruising the article, its fibrous structure is disintegrated in a degree proportionate to the amount of violence to which it is subjected. The nutritious particles are for the most part enveloped by the fibre, which to a great extent protects them from the action of the juices of the stomach. By breaking up the fibre the gastric juice is allowed to come in contact with the digestible portions of the straw; and, consequently, a larger amount of these substances is assimilated. Straw is one of those substances which may be cooked or fermented with advantage, as by either of these processes the fibrous matter is softened and broken up to such an extent as no longer to protect the albuminous, oily, gummy, and in other useful matters from the action of the solvents in the stomach—*Prof. Cameron, Editor of the Irish Agricultural Review.*

## Steam Cultivation.

[We take the following notice from a recent number of the *Bucks Herald*, (English) Mr. Lewis Taylor, who seems to have taken up steam cultivation in England as an avocation, is brother to Mr. Edwin Taylor, landscape gardener, both of whom were late residents of this city. The progress of steam as a motive power in agricultural operations, if not rapid, is, at least, constantly progressing and increasingly satisfactory.—Eds.]

To the enterprise of Mr. Fowler, of the prebendal Farm, many persons in Aylesbury and the surrounding neighborhood—whose knowledge of the cultivation, or rather the turning up of the soil, by means of steam power, entirely rested upon what they heard and read—have this week had the opportunity of seeing for themselves the practical working of a system which there can be no doubt will, ere many years elapse, entirely revolutionise the most important of farming operations. On Mr. Fowler's farm “Howard's New Patent Double Action Steam Cultivator” has been at work for several days, accomplishing its task to the satisfaction and admiration of all who have been attracted to the spot. Mr. Lewis Taylor, the gentleman who owns the cultivator, and superintends the operations, with the most cheerful courtesy and kindness gives to the spectator any information as to the cost, capabilities, &c., of his beautiful apparatus, answers any question which may be suggested by its working, and generally, after a short conversation, puts one quite *au fait* with the cultivation of the soil. It is not necessary that we should enter into a long and technical description of the working of the apparatus which constitutes either a steam plough or cultivator. This has been done repeatedly in our columns, but as this “New Patent Double Action Steam Cultivator” is upon a new principle, a few words are necessary. The desideratum in other cultivators (and this applies to steam ploughs as well) was the very thing which in this one is accomplished—namely, its double action, thereby giving increased facilities for easily working and saving time, considerable trouble, and some expense. It is a very neat and easily handled implement. It is made with a ribbed wrought-iron frame, combining great strength with comparatively little weight, and is fitted with five tines or legs, but can be used with four, three, two or one, according to the depth, the tenacity, and the heaviness of the soil. On Mr. Fowler's farm three tines are being used. The shares are made of various widths—from two up to ten inches—this too, as a matter of course, depending on the strength which in the judgment of a purchaser the implement

should have, and the amount of work it is expected to accomplish. The tines rock on the frame, so that the points, when working, are depressed, and the hinder ones slightly raised. The wheels are steered by the ploughman, who rides on the implement, alternately at each end, according to the direction in which he is proceeding. When a stoppage occurs, or should occur, either from the soil being extra hard or foul, the steerer can stop it instantly by giving a signal to the man attending the engine; it can then be drawn back and again driven at full speed. The "porters" upon which the wire rope runs in the line of the soil being turned up—or in other words, "the porters" which require constant shifting as the cultivator does its work—act very efficiently, and can be attended to by the most inexperienced boy. The anchors at each end of the line traversed by the implement require, of course, to be shifted each journey, and this too, is easily accomplished, and without more than a momentary stoppage. As a cultivator, the implement performs its work in first-rate style. The soil is as effectually as it is rapidly torn up and turned over, at a depth which can be varied according to circumstances from six to twelve inches. The whole apparatus—engine (which is a portable one, and of 10 horse-power), "porters," and implement—can be attended to by four men and two boys, and, eight acres per day can be easily accomplished, at a cost we believe, of 15s. per acre if the soil is once turned over, and 25s. per acre if twice or cross cultivated. From these figures farmers can make their own calculations as to the economy of the implement, and as to its efficiency they will, we think, be satisfied the moment they see it at work. As will be seen by an advertisement in another column, Mr. Taylor intends making Aylsbury his head quarters, so that the farmers of the Vale will have the opportunity of doing what Mr. Fowler is doing—practically testing the cheapness of steam cultivation.

### The Autumnal Fallow.

In the subjoined article from the *Mark Lane Express*, written by a "Practical Farmer," will be found much that is applicable to our condition and wants in Canada. We have now, gang ploughs, horse-hoes, scarifiers, &c., well adapted for fall culture, opening up the soil to the influences of air, light and moisture, and for eradicating weeds. The latter is an object of paramount importance, as is well known to every practical agriculturist. The practice of autumn cultivation in some form or other has been steadily gaining ground at home for many years,

and may now be said to form a distinctive feature of British Agriculture:—

Amongst the many modern improvements in agricultural practice none has received more favor or become more general than autumnal cultivation. Wherever we travel at the close of September or the beginning of October, in this country, we find the practice universally adopted, and being carried out in a variety of mode. In ordinary practice, the skeleton plough, and broad-share plough, and even the common plough, are brought into requisition; but the more modern course is to resort to the very many cultivators and scarifiers lately introduced, the manufacturers of which are to numerous to mention: but the implements which have received most patronage are the "Bentall," the "Biddell," the "Clay," the "Carson," the "Coleman," the "Howards," the "Ransomes"—scarifiers and cultivators named after their respective makers—besides others of considerable note, and also many of local construction—in fact, any and every implement competent to break or "smash" up the soil.

The great benefits derived from autumnal cultivation are mainly the aeration of the soil, the eradication of root-weeds, the promoting of the growth of all annuals, and their subsequent destruction, the injury done to, and almost annihilation of the insect tribe, and the aid thus given to more speedy subsoil drainage—all very important, and demanding the prompt attention of every farmer. The aeration of the soil at this precise period is of much greater importance than is generally attributed to it. It is at this season that all vegetation has pretty nearly arrived at its full growth. The cereals, of course, all are ripe; and the decay of straw and stubble is very great. The green crops are also at their full growth, and decay in leaf is rapidly proceeding. The potato crops, cloverleys, &c., are bare of leaf also. The foliage of the trees and hedgerows is all giving way; the ditches and ponds give out their odours, unmistakably manifesting the decay of vegetable matter; the dews and fogs of autumn are many and heavy. All this combined must produce, eliminate, and diffuse a vast amount of vegetable effluvia, with which the atmosphere is, in my humble opinion, heavily charged, and which, to unscientific observers, is sufficiently proved by the malarias which commonly prevail at this season. Now the great thing is to break up, "smash up," and prepare the soil as minutely as possible, for the reception of these fertilizing vapours, this floating effluvia. If it is not thus broken up, the deposit by the night-dew is speedily taken up by the day's sun, and no benefit arises: it cannot penetrate the hardened soil. But if it is properly prepared, these fertilizing influences are received, and at once appropriated by the soil; and the advantage of an autumnal fallow, and in a great measure of a real or dead fallow, is ex-

perienched; the old adage, "One autumn ploughing is worth two summer ones," is verified.

The eradication of root-weeds is very important, and in a fine autumn is often effected satisfactorily. It is particularly requisite on lands not quite prepare for wheat-seeding. The present season is a peculiarly favorable one, and no time should be lost. The land should be broken up to a considerable depth—at least; below the rootlets of the weeds—by a competent implement, and ought then to be well-worked by harrows, rollers, &c. The weeds on some stiff soils will dry up and die; but on the far greater majority of soils they should be collected, gathered up, and burnt, or be carried to a fold-yard for mixing and treading down with the farmyard manure. In this way it is most serviceable; but if burnt, it is almost valueless. The promotion of the growth of annual seeds of weeds is another important consequence attending autumn culture, as by the various processes of cultivation they are brought into contact with the soil, and made to vegetate. The young plants are then easily destroyed by subsequent culture. Another benefit is the wholesale destruction of innumerable insects, slugs, worms, grubs, &c., &c., both in their larvæ state and at full growth. The repeated disturbance of some of these insects has a marvellous effect. The little beetles of the wireworm tribe, by some instinct or other means, know this, and will not deposit their eggs where such operations are going on. The chosen abodes of the various grubs, wireworms, &c., &c., are broken up, and vast numbers become the prey of the feathered tribe; others are exposed out of season, and therefore die.

Another benefit is, that this pulverization contributes greatly to facilitate the passage of the autumnal rains through the soil into the subsoil drains, thus giving it a quick riddance of superfluous water, and at the same time procuring a more copious supply of ammonia from the rains that fall. It is by the passing through of rain water that the soil receives its chief supply of ammonia, which is so conducive to the full development of the wheat plant, and consequently it is one of the great acquisitions attained by autumn fallowing. Taking then into consideration these principal items of the subject, it will, I trust, be manifest that autumnal fallows are of immense value, and cannot be too highly recommended.

The modes of cultivation are almost as various as the soils cultivated. The greatest acquisition in modern times, for this purpose is the application of steam to cultivation. It is a wonderful improvement, and worthy of adoption wherever it can be carried on without obstructions from stones or roots; and it has arrived at that height or degree of perfection which renders it available to men of moderate means. The process can proceed under almost any circumstances. No soon-

er is a field cleared than the steam-cultivator may commence its operations, the horses of the farm continuing the cartage; besides, it requires so few hands, under its best phases, that no difficulty can arise in that respect, and no mode of cultivation yet practised can equal it in the effective power and correct application. The breaking or "smashing up" by it is beyond the power of horses or animal life; the depth reached is so great, the work done is so regular, both in depth and fulness, and the whole is in such a business like character, that hitherto nothing has equalled it, notwithstanding the great advance made in agricultural mechanics as applied to cultivating implements. Steam cultivation then will undoubtedly be invaluable for effecting the autumnal fallow.

It would seem superfluous for me to point out any course of management best adapted to secure a good autumn fallow; but it must be remembered that we do not always write to experienced farmers, nor do we presume to instruct them. Our aim is more to inform the inexperienced and youthful farmer. We would then say, that as soon as possible after the crop is led or carried, the land should be harrowed or well raked, in order to get off all shaw and stubble likely to impede the working of implements. The scarifier should then be passed through it at as great a depth as appears desirable, and in this way it should first take the furrows lengthwise, and then take the whole transversely across the field: by this means the furrows get well broken up. After an interval of a few days, a drag or heavy harrow should follow the scarifier, to be succeeded by light harrows and roller, to pulverize thoroughly, that all may obtain a thorough cleansing. The interval named is to allow time while in its roughest state for atmospheric influences to operate. When seed time arrives, it should receive the ordinary ploughing and subsequent management necessary to complete a good seeding.

One other great, but collateral advantage derived from this course is, that it will not be requisite to drill in so much seed. The slug and noxious insects being destroyed or greatly thinned, the occupier may depend upon securing a full plant, at least from their depredations; besides, the land is in a far better state for promoting the rapid growth of the wheat plant. Moreover, it has been proved to demonstration that a good or strong plant from a thin seeding is more prolific than a thick planting from thicker seeding. In my own business, after these processes I do not drill in more than from five to nine pecks of wheat per acre, and the season must be bad indeed that will induce me to drill so much as nine pecks. I make six pecks suffice if all is favourable. The state of the soil, the condition in which I am able to get in the seed,

the state of the weather, and the time of year, all rule me, in their turn. The better the land works the more favourable the season, the less seed I drill; but *vice versa*, the more I drill, but never to exceed nine pecks per acre of good seed.

### Pastures for Milch Cows.

In the last volume of the Transactions of the New York State Agricultural Society is an excellent paper on Dairy Farming from the pen of Mr. Willard of Herkimer County, from which we select the following:

Old pastures that have a fine thick heritage of several kinds of grasses adapted to the soil, and coming to maturity at different seasons, will generally be found to produce more milk and from which a richer, better flavored, and finer quality of butter and cheese are manufactured, than from the rank growth of grasses on newly seeded lands. Again, newly seeded lands will not bear that close cropping, nor will they endure drouth like permanent pastures.

Doubtless when the land has been underdrained, deeply subsoiled, enriched, and then seeded with a judicious admixture of grasses of the several species best adapted to the soil and climate, a permanent pasture of the best character may be soon obtained, and would amply pay all expenses for such cultivation. Yet few, comparatively, can be induced to enter upon this system of farming, and the next best course is to be considered.

In the treatment of old pasture lands injured from close cropping or other causes, but not wholly run out, it will generally be better not to break up, but to leave them for a part of the season to resuscitate, running a harrow over the ground in early spring, and sowing a mixture of timothy, blue grass, red top, the clovers, red and white, and orchard grass, making an application of plaster, pulverized bones, ashes, salt, or other stimulating fertilizers. Ashes, leached or otherwise, remove mosses and are a valuable application to grass lands.

There are pastures in Herkimer county which have not been broken for more than forty years—many that have never been plowed perhaps but once or twice, years ago, when the country was new, that are yielding an abundance of nutritious food, enduring year after year close cropping and drouth, without any perceptible injury or tendency to run out, and yet have received no top-dressings, beyond the usual application from time to time of gypsum. The grass of these lands spring up green and fresh, with a thick fine bottom, a marked contrast throughout the season to occasional patches on the same soil recently re-seeded. Stock too, it will be observed, are to be more frequently found on these pastures, thus showing that the grass is sweeter or more nutritious than on the newly seeded parts.

To plow and cultivate such lands, would be to destroy the original grasses, and after re-seeding, many years must intervene before the new grasses can obtain that firm possession of the soil, and the enduring vigor and variety of the old sod.

The reasons for the successful growth of these natural grasses need not here be discussed—the decomposition of leaves, wood roots, and other vegetable matter, for centuries, seems to have accumulated a surface soil, capable of supplying the best possible food for growing these plants in perfection, which, intermixed as they are with artificial grasses, timothy, clover, &c., form a more closely matted sward, and produce an herbage more nutritious, and better adapted to the animal system, than that from newly sown seeds on recently cultivated lands.

There are large tracts of country, the soil of which is unsuited to hold the grasses of any approved kind, for any great length of time.

They are not natural to grass, and therefore unreliable, and cannot be profitably employed in stock farms. The character of the soil is usually of a light texture, sandy or gravelly; they will require to be frequently plowed and re-seeded with clover, timothy, or other rapidly maturing grasses, and for short periods may yield good crops. But such soils do not seem to contain the elements necessary for the establishment of permanent pastures and meadows, being more suited to the growing of grain and other crops.

These lands stretch away through the middle, western and southern States, leaving comparatively but narrow belts and patches of land adapted to the dairy. So far, experience has shown that the real dairy soils are very limited in extent, and this fact while it gives assurance that the constantly increasing growth of our country renders certain a constantly increasing home demand for the products of the dairy, and while the nature of the country itself precludes any great or extended competition, should at the same time stimulate those who have been so fortunate as to be in possession of the favored soil, to bring it up to its highest capacity, and make their staple products of the best and choicest quality.

As a top-dressing for grass lands, the application of gypsum, salt, ashes, bone-dust, lime, decomposed urine, well rotted manure applied in fall, composts of manure, river mud, road scrapings, or muck; each and all have a marked influence in promoting the growth of grass.

A more general use of bone-dust, it would seem, should be adopted, in order to return back to the soil the phosphates which are annually taken from it in considerable quantities by milch cows. So large an amount is there taken off in the milk of cows, and for the annual production of their young, that the use of bone-dust on the older dairy farms, it is believed,

will soon become a necessity. Wherever employed as a top-dressing for grass lands, its results have been highly beneficial, and its application on dairy farms should be as universal as that of gypsum.

### The Lower Canada Provincial Exhibition.

The Provincial Exhibition opened at Sherbrooke on Wednesday last. The day was as fine as could be desired but as a *Provincial Show* it can hardly be pronounced a great success. The leading feature was the cattle and particularly the working oxen. Several good judges from abroad said that the show of cattle was the best ever exhibited in the Province. The Townships have no occasion to be ashamed of the specimens of cattle they had on the ground. Stanstead took the lead in cattle, their team of ten oxen was awarded the 1st prize, Compton the 2nd, and Ascot came in No. 3. These three teams of ten oxen each was a right worth looking at by a lover of good cattle.

Of fat cattle there were not a large number, but some splendid animals. Samuel Towser, of Quebec, exhibited a pair of fat oxen, girt 9ft. 2in., 17 h. high, and said to weigh over 6,000 lbs.; he had also a fat cow, a perfect mass of fat, she measures 31 in., across the hips, girt 8 feet 9 in. The oxen were recently sold for \$600. They are good samples of what can be done by high feeding, but we should fancy not at much profit.

There was a good display of sheep, the Leicesters taking the lead.

The swine were not very numerous, but comprised some very handsome animals.

There was a very good display of horses of all kinds.

Flax was perhaps the most important article exhibited. There were several specimens of dew-rotted, which was necessarily coarse; some specimens of steeped were much finer. There was a sample of flax rotted under the snow. The results are as satisfactory as steeping; this sample was exhibited by Mr. Knox, of Lachine. There was a good sample shown by Mr. Boa, with the seed from it, showing that this crop will yield both seed and fibre of a fair quality at the same time. Mr. Boa also exhibited a sample of hemp in the stock, about 12 feet high, and a sample of the fibre made from it which looked as well as flax.

The implements and manufactures were not very numerous, among them were:—ploughs, sugar pans, fanning mills and cultivators, by Charles Brooks, Lennoxville; cast steel and iron ploughs, cultivators and harrows, by Jas. Patterson, Montreal; Sugar boilers and ploughs, by Samuel Tuck, Sherbrooke, among them was a beautiful finished breaking up plough. R. Lewis, of Melbourne, exhibited an ingenious

churn on the principle of the common dasher, moved up and down by a crank of a saw mill, also a farm gate hung upon rollers. C. R. Parks, of Waterville, a dasher churn moved by crank, which gives the dasher a twisting motion; Eadon, Wyatt & Co., of Montmorency, a mangle for ironing clothes, carrying a pressure of 1,200 lbs.;—also a washing machine and mangle combined, also fanning mill and churn; M. Capel, of Ascot, a chain harrow or pulverizer, and a light adjusting harrow; Henry Rose, of Stanstead, Wood's mowing machine; Matthew Moody, of Terrebonne, a one and a two horse power thrashing machine, horse rake, clod crusher, and a combined reaping and mowing machine; St. Germain & Refus, of St. Hyacinthe, a horse rake; John Gilmall, Stanstead, a roller; C. P. Mallory, Huntingville, a large cylinder roller.

S. T. Rose, of Sherbrooke, exhibited a very beautiful side-board made of bird's eye maple, and chiffonnier of the same material, both of which for beauty of workmanship were much admired.

The total number of horses on the ground numbered 175; cattle 354; sheep 136; swine 40; agricultural implements 90; besides the products of the field.—*Montreal News*.

### Facts from the Census for Upper Canada.

The quantity of butter made in 1861 amounted to 26,828,264 lbs., and of cheese to 2,687,172 lbs.

In 1851 there were 16,064,532 lbs. of butter, and 2,292,600 lbs. of cheese made, or

|           |                         |
|-----------|-------------------------|
| 1861..... | 26,828,264 lbs. butter. |
| 1851..... | 16,064,532       “      |

|                    |                         |
|--------------------|-------------------------|
| Increase in 1861.. | 10,763,732 lbs. butter. |
| 1861.....          | 2,688,172 lbs. cheese.  |
| 1851.....          | 2,293,600       “       |

|                    |                      |
|--------------------|----------------------|
| Increase in 1861.. | 394,572 lbs. cheese. |
|--------------------|----------------------|

Beef in barrels:

|           |         |
|-----------|---------|
| 1851..... | 113,445 |
| 1861..... | 67,508  |

|                    |                    |
|--------------------|--------------------|
| Decrease in 1861.. | 45,937 bbls. beef. |
|--------------------|--------------------|

Pork in barrels:

|           |         |
|-----------|---------|
| 1861..... | 336,744 |
| 1851..... | 317,010 |

|                      |                    |
|----------------------|--------------------|
| Increase in 1861.... | 19,734 bbls. pork. |
|----------------------|--------------------|

The increase in barrelled beef and pork, and consequently in the export of these articles, is very small in ten years, and shows that in this branch of the provision trade Upper Canada has not made such progress by comparison with the years 1851 and 1861.

The exports from the Province of beef, pork

butter, and cheese, for the years 1859, 1860, and 1861, were as follows:

|        | 1859.          | 1860.          | 18 1.          |
|--------|----------------|----------------|----------------|
| Beef   | 3,235 cwt      | 1,846 cwt      | 1,598 cwt      |
| Pork   | 36,984 "       | 63,109 "       | 81,032 "       |
| Butter | 3,750,296 lbs. | 5,512,500 lbs. | 7,275,426 lbs. |
| Cheese | 323 cwt.       | 1,100 cwt.     | 2,628 cwt      |

The Fisheries of the Upper Province do not show that increase which might be expected from the valuable resources of the great lakes.

In 1851 there were 11,886 barrels of fish cured; in 1861, 10,013 barrels; 2517 quintals, and 175,744 lbs. of fresh fish sold.

In Michigan, which is the largest inland fish producing state, the value of white fish returned in 1860, amounting to \$250,467. There is yet a vast field open for remunerative enterprise in the fisheries of Lakes Huron and Superior. The whole of the north shore of Lake Huron with its million islands will yet yield great wealth to the country from its clear and cold waters. The art of the preservation of fish is as yet unknown in Canada, or rather it is not practised. In Germany, France, and Britain, Pisciculture is now an acknowledged department of national importance. It would be a wise economy on the part of the Government to examine into the working of fishing regulations and Pisciculture now in operation in Europe. A few skilled emigrants from France, Germany, or Britain, would soon enable Canadians to rejoice in the possession of the finest fresh-water fisheries in the world.—*Journal of Board of Arts and Manufactures.*

### The Radish as a Field Crop.

"Once upon a time" the leaves of the radish were boiled and eaten, but in these days they are subjected to neither one nor the other of those processes. The root is, however, in its raw state, as all our readers are aware, one of the dainties of the table.

Many of those who devote themselves to the important study of dietetics consider the use of raw vegetables as objectionable; but, be their objections groundless or the reverse, it is certain that a vegetable which admits of being eaten raw with advantage must certainly be a good nutritious article of food when cooked. We once tried the experiment of eating matured radishes, not as salad, but cooked as any other boiled vegetable, and we found the flavour rather agreeable than otherwise. Boiled radishes, roots and tops, form excellent feeding for pigs—how could it be otherwise! for what is good food for the family of man must surely be a luxury for the swine tribe. Horses, too, we have known to eat radishes, as they would carrots, with avidity; and, indeed, we have no doubt but that these plants would be found on trial to be readily eaten by every kind of farm animal. But it may be asked why we recommend the use

of radishes as food for man and his "subjects in creation" when there are so many better articles in common use—potatoes, turnips, mangels, *et hoc genus omne*? We will try to give a satisfactory answer to this question.

Between the departure of the turnips and the advent of the new grass there is a kind of agricultural interregnum. We want a good tuberous, bulbous, or tap-rooted plant to fill up this interregnum, and such a plant we have to some extent in the radish. The root is certainly a small one; but, then, it is so rapidly developed that a good supply can be had thirty days after the sowing of the seed. Two crops may easily be obtained from land under potatoes; one before the cops covered the ground in spring, and the other in autumn, after the tubers have been dug out. If the land be altogether devoted to radishes, four crops in the year is the least number that may be reckoned upon, and if spring and late autumn be mild, six crops are not only possible, but highly probable.

The yield of radishes, when cultivated in the garden, is about 2,500 plants per perch; and as on an average each radish weighs about one and a-half ounces, the weight per perch will be nearly 230 lb., which is at the rate of nearly nine tons per statute acre, of which one-third will be tops. These figures relate to the careful cultivation of the plant, under the most favourable conditions of growth. We must not, therefore, expect to get so large a return if the plant be cultivated in the field; but keeping fully within bounds we may assume that a single field crop of radishes yields:—

|                         |         |
|-------------------------|---------|
| Of roots.....           | 5 tons. |
| Of tops and leaves..... | 2½ "    |

Total.... 7½ tons.

Now, although we believe no loss would be incurred by devoting a portion of the farm solely to the cultivation of the radish, still it is not our object to recommend the appropriation of any part of the farm to such a purpose. What we

want to bring under the notice of our readers is simply the desirability of cultivating a root crop which may be perfectly matured before it is time to sow turnips.

And now a word or two on the mode of cultivating this plant, and we dismiss the subject at present.

There are several varieties of the radish. The long white, white Russian, red necked white, and purple, are kinds adapted for spring. The turnip-rooted radish, adapted for summer, comprises several varieties, of which the following are the principal:—Early white turnip, white turnip, purple turnip, pink turnip, and new yellow short-topped. The autumn and winter varieties embrace the yellow turnip, white Spanish, oblong brown, large purple, and winter Spanish. The turnip-rooted, or Spanish kinds, alone should be grown in the field.

The radish can be cultivated on any kind of ordinary soil, but it appears to delight in a light and porous loam, containing a moderate amount of organic matter. Except for early and late crops, an open situation is the most desirable.

The seed may be sown either broadcast or in drills; the latter is by far the preferable mode, and as the seed is large there is no difficulty in its regular distribution. The seed is cheap; but this should not induce thick sowing, which, if practised, causes an excessive development of the tops, and a consequent hardness and toughness of the roots. The seeds should be placed a quarter of an inch below the surface, and care should be taken to protect them from the manure, which, indeed, should not be applied at the time of sowing. The drills for the spindle rooted kinds should be about three inches asunder; those for the turnip rooted, drills about seven inches apart.

When the seedlings exhibit half-a-dozen leaves or so they must be thinned; a space of three inches should intervene between the long-rooted kinds, four for the turnip-rooted, and six for the Spanish and other large varieties. The latter kinds are best adapted for high cultivation.

In conclusion, we would suggest that this plant should at once get a fair trial as a stolen crop. If it succeeds as such, it will not be the first gift of the gardener to the husbandman. Were not the red beet and the mangel-wurzel once only known as the produce of the gardener? We commend, therefore, the radish as worthy the attention of farmers in general, of small farmers in particular, and cottars especially.—*Dublin Agricultural Review.*

### Rot in Cattle.

We hear much about rot in sheep, and not without good cause. We know extensive districts where a loss of 15 or 20 per cent. must have been sustained this season. Ewes and hogs are being sold now in apparently blooming condition, but in reality "rotten," and to keep them on would only amount to the loss of the bare salvage procurable for their use. These remarks concern more the English and the Irish than the Scotch farmer; nevertheless, a season of incessant wet brings in its train disease of a special kind; and though some parts are more favoured than others, still, very generally distributed over the United Kingdom we notice the effects of an unusual period of constant rains. We have had ample opportunities of late to see the condition of stock in different parts of the country after three months' and more grazing. In the most fertile districts of Scotland, and on the rich grazing lands of England and Ireland, there are many instances of animals not improving in the least in condition since the 1st May. It is also worthy of notice that any weakly or infirm stock, especially in ill drained districts,

has suffered severely from the very miserable condition of grass. Wherever the mouth and foot disease has appeared—and where has it not?—the number of deaths has been unusually large, in consequence of the starved condition of all lean stock. It is well known that this disease is not a very deadly one, but we have to record losses of 5 and 10 per cent., and sometimes far more, amongst calves and year old's. There are parts where deaths have been fewer, but all know how low in condition cattle get with this disease; and where the grass has been bad, the chances have been small of restoring the animals even to the state in which they were before being placed on pasture land. But it is our object to-day to allude to a disease concerning which little has been said in this country, viz., rot in cattle. It is especially prevalent in low, damp, situations, and on the marshes scattered throughout the continent of Europe; and also in America herds of cattle are much injured by attacks of the rot.

It is the same malady as the "sheep rot," but sheep certainly suffer more certainly and more severely from feeding on damp plains than cattle. The low condition which we have said may be witnessed very generally amongst grazing cattle has been most favorable to the development of parasitic disease; and the fluke has perhaps been amongst the most busy of the destructive entozoa. A rough coat, dry skin, prominent ribs, sunken flanks, arched back, pallid membranes, all indicate an unhealthy state. A small and frequent pulse, capricious appetite, yellowness of the eyes and mouth, coldness of the extremities, and the absence of symptoms of acute fever, establish, with the other signs mentioned, that the animal is suffering from that slow, lingering, and destructive disease, "rot." Swellings of the extremities, and especially an accumulation of fluid about the throat, supervene as the animal grows weaker and weaker. We have seen cattle with the worst symptoms of rot attacked by parasites which develop in the orbits, and may be seen rolling over the front of the eye-fall. Lice and the parasitic fungi which frequently infect the skins of young cattle abound in rotten animals; and this season many cases have been complicated by the accumulation of strongyli in the lungs and wind-pipe.

The loss amongst cattle suffering from this disease is considerable, especially in consequence of the difficulty of feeding them even when the malady is mild. It is not so deadly as amongst sheep, and as amenable to treatment. Artificial food should be given freely with common salt and preparations of iron. No tonics are so effectual as the ferruginous compounds, and if parasites abound in the skin, it is indispensable to clean the latter thoroughly by repeated washings with soap and water, and the application of washes to destroy the animalcules.—*Scottish Farmer.*

## Agricultural Intelligence.

### Sale of Stock at Guelph.

On Wednesday last an important sale of stock took place on the farm of Mr. F. W. Stone, President of the Agricultural Association, Guelph. The attendance was not very large, and only a few stock-breeders from a distance were present. Mr. Stone's splendid stock of cattle was first offered, but as the bidding was far from spirited, only a portion of the lot was sold. Lady Cramer, a red and white cow, calved 24th July, 1850, was knocked down to Mr. Thomas, McCrae, for \$100. Young Velvet, calved 14th June, 1853, was sold to Mr. F. Lowell, of Galt, for \$180. Sanspareil, a two-year old heifer, was sold to the Hon. David Christie for \$180. Sanspareil, 5th, calved 13th February 1860, was sold to Mr. Walter Raikes, of Barrie, for \$180. Walter West bought Goldfinder, a yearling heifer, for \$120, and Mr. Arthur Hogge, bought the second Duchess of Oxford, calved 12th December, 1860, for \$205. Hon. David Christie bought Miss Margaret, calved 27th November, 1861, for \$135. Only one aged bull was sold—President, to Mr. Jas. Carter, Puslinch, for \$80. Royal Duke, calved 5th December, 1861, was sold to Mr. Thomas Clarke, Eramosa for \$120. Mr. Arthur Hogge bought Earl of Gloucester, calved 15th December, 1861, for \$100. The sheep did not go off well. A gentleman from Connecticut bought one Cotswold two shear ram for \$45. A Leicester two shear ram was sold to Mr. James Cowan for the same sum. The others sold—6 or 7—were bought by persons in the district at prices averaging \$15 each for Southdowns.—*Leader.*

The agricultural statistics of Ireland, just published for the current year, show a decrease in the live stock of the country since 1861 by nearly 10,000 horses, 220,000 cattle, and 100,000 sheep. Pigs have increased 50,000. The value of the live stock is on the whole less by £1,500,000. This is attributed to the distress consequent on scarcity, which has induced excessive sales. The average in grain of all kinds is less by 72,000, that in Potatoes alone being less by 116,000 acres.

**COMPOSITION OF SEA WEED.**—Sea-weeds, in the condition of mixture generally, contain in 100 parts of ash, silicic acid 3.00, carbonic acid, 13.58, phosphoric acid 4.59, sulphuric acid 6.22, peroxide of iron 2.53, lime 18.15, magnesia 6.48, potash 12.77 chloride of potassium 9.10, solide of potassium 1.63, chloride of sodium 22.08.

## Horticultural.

### Hamilton Horticultural Society.

The third and last Exhibition of the season of the Hamilton Horticultural Society, was held in the Mechanics' Institute on Friday the 19th ult. Seldom have we seen a finer display of fruits. The hot-house, and open air or hardy grapes were well worthy of the notice they received. The Black and Muscate Hamburgs, Muscate of Alexandria, and Bowood Muscate, Greely Frontignaro, Royal Muscadine, and Black St. Peters, were all excellent. Amongst the hardy varieties, Hartfords, Prolific, Clinton, Delaware, Concord, Diana, and Rebecca, all good specimens, and very creditable to the growers. The Peaches and Nectarines were beautiful. The early Crawford and Kensington, exhibited by Mr. Freed, were the finest we have seen for a long time. Plums, Apples and Pears were all in abundance, also some Damsons, Quinces, Crabs Siberian, mammoth and other Tomatoes, Melons scarlet and green fleshed, Water Melons, Citrons and Squashes of various kinds, Capsicums as large as pepper boxes and hot as fire.

**FLORA**—in hot and Green-house plants was not so well represented as we have seen on former occasions at this time of the year. The hot and green-Houses of W. P. McLaren Esq., produced some Fuchsias. Fine plants of *Cytisus reflexus*, *Bouvardia Hogarth*, *Bouvardia leiantha*, a splendid plant of *Stephanoth floribunda*, and a fine lot of Cockscombs. There was a good display of cut flowers, comprising Dahlias, Phloxes, Asters, Hollyhocks, French and African Marigolds, Verbenas, Stocks. Two collections of native plants, one of 12 varieties by Mr. Freed, the other of 24 by Mr. Sanderson, junr. Bouquets for the ladies, and Bouquets by the ladies, hand and table, of all shapes and sizes, made up of the prettiest flowers that could be got: such as the Princes' Feather, Rue and lime, Forget-me-not, and other sweet things, with Love-lies-bleeding; amongst the rest, one of native flowers by Mr. Sanderson, junr., was very much admired.

The *Vegetable* department was well represented, but not so largely as we have seen it before at this time of the season. All the productions were good; Cabbages and Cauliflowers large and excellent, Brussels Sprouts, Carrots, horn, orange and Altringham; Turnips, white and yellow, Corn sweet, Celery red and white, Onions and Musselbough Leeks, Potatoes, Parsnips, Salsifys, Scotch Kail and Mushrooms, with two large collections of vegetables, by Messrs. Taylor and Sinclair.

The amateurs came out well in all the departments.

In the afternoon an interesting ceremony took place in the presentation of two medals, one given by Adam Brown, Esq., President of the

Society, to the Gentleman's Gardener who keeps his garden and grounds in the best order, and his flower-bed most tastefully arranged during the season; the other, by the Directors, to the Market Gardener who, during the season, keeps his grounds in the neatest order and best state of cultivation. The first medal was a model of beauty and good taste, bordered by the Maple Leaf, and surmounted by a Beaver emblematical of Canada, with the insignia of Horticulture on the ribbon, the spade, hoe and rake. It was manufactured by Millidge & Son, Princess Street, Edinburgh, and bore the following inscription: "Presented by Adam Brown, Esq., President of the Hamilton Horticultural Society, 1862, for the best kept and most tastefully arranged Garden and Grounds." "On the other side was inscribed. "Gained by Hugh Shaw, Gardener to R. Juson, Esq." The Directors' Medal was of good taste, and bore the following inscription: "The Directors of the Hamilton Horticultural Society, 1862, to the Market Gardener who has kept his grounds in the best order during the season." On the other side. "Awarded to James Wildes."

The presentation was made by the President, who appropriately addressed the successful competitors, very specially remarking on the good obtained by well organized systems. Messrs Shaw and Wildes responded.

Such actions by a society are not only stimulating, but also very beneficial to all parties. We therefore hope that as a good beginning has been made by the Hamilton Horticulturists they will continue to bear it up, and that other Societies will follow their example.

GEO. LAING.

Hamilton, 6th Oct., 1862.

### Advice on Planting Fruit Trees.

As every season for setting out trees approaches, many begin to turn their attention to the proper selection of varieties to occupy their intended fruit-gardens. A few general hints may therefore be useful at the present time, and serve as an answer to the many inquiries which we receive on this subject.

There are two prominent objects with tree-planters, namely, raising fruit for market, and securing a family supply. The present suggestions refer more particularly to the latter, and we shall endeavor to show in a general way how a family may best attain this luxury at all seasons, or in other words, how the complete circle of fruits may be obtained. It is however not merely a luxury—for nothing in the form of diet contributes better to the preservation of health during the heat of summer and the changes of autumn, than a regular and constant supply of good well-ripened fruit, partaken in moderate quantities. It also has economy to recommend it—because the table that is furnished with fresh or cooked fruit needs but little

of the more costly provisions from the butcher's and confectioner's.

The first question that occurs with many, is, what fruits will give fresh fruits to the best advantage throughout the year, and the second is, how many trees and plants will be needed, and how much land for their successful growth. A third question is not unimportant, namely, how long after we have prepared the ground may we expect to obtain good crops.

To answer the first question, we would name those sorts first that ripen earliest in summer. These are all exclusively small fruits. The early strawberries take the lead in the list, giving in the Northern States ripe berries in the first two weeks of summer, but varying in season nearly one month with Northern New-York and Southern Pennsylvania. A locality well sheltered from winds, and where the sun's rays are not impeded, will ripen the berries some days sooner than a more exposed place. Unlike trees, there is no fear of losing the crop by the cold of winter—and if there is any danger of the plants being injured, this is easily removed by covering the plants with straw, or spreading a coating of evergreen boughs or leaves over them.

Next to strawberries, and within a few days of them are the early cherries—such sorts, for example, as the Early Purple Guigne, May Bigarreau, Belle d'Orleans, &c. We have nothing to compete at all with cherries and strawberries, currants and raspberries, the next on the list, being several weeks behind them. The best varieties of these four, if planted in sufficient quantities and well cultivated, will give an admirable and delicious repast for every table for six weeks or more from the first until after the middle of summer.

About the usual "harvest time," some important additions are made in the larger fruits. The Primodian plum, the early apricots, and the earliest apples and pears then begin to ripen. These are again succeeded by the first peaches, and the many sorts of pears, apples, plums, &c., which continue to mature successively through the whole of autumn. The first half of autumn is marked by the most profuse abundance; as winter approaches, the number becomes smaller, and special care is needed to procure plenty of good winter pears, and with ordinary management very few are ever found towards spring. Well cultivated and *well ripened* hardy grapes, however, are very easily kept through winter, and these and winter apples may be best relied on at this season of the year. The only fruit that can be depended on for a good supply in spring until strawberries again appear, are winter apples; although such late pears as the Easter Beurre, may with extra pains be had at that time, but families with moderate incomes will hardly care to live on such luxuries as bring quickly in market three dollars a dozen, or twenty or thirty dollars per bushel.

In thus pointing out how the yearly circle can

be secured, we have omitted hot and cold house grapes, which of themselves have been made to give ripe crops every month in the year. The expenditure required for such a supply, like that of Easter Beurre in spring, is beyond the means of moderate families.

The next question is, how many trees and plants will be required to give the yearly supply, and how much land must they occupy. The simplest way to answer, will be to observe the usual amount yielded per acre, and reduce the amount to a family supply. Strawberries of the most productive varieties, such for example as the Wilson, Downer, and under the most favorable auspices, the Hovey and Triomphe de l'And, will yield 200 bushels per acre, if cultivated as well as good gardeners do the work. A family wants half a peck per day, for a month or more of time—equivalent to a bushel in eight days, or about six bushels for the season. One thirtieth part of an acre, or five square rods would be enough. Very few families provide so much as this, and very few have a quart or more of berries on each table. It will be observed that as the strawberry crop scarcely ever fails, such an estimate may be made with considerable accuracy. As soon as we come to *trees*, we are in great uncertainty, and a tree of Early Purple Guigne may give us two or three bushels, or not a tenth of this quantity. Where this fruit usually succeeds, two or three early trees will commonly afford all that a family may desire in connection with the strawberries—to be followed of course by succeeding kinds, such as Governor Wood, Coe's Transparent, Black Tartarian &c., and the best latter sorts. If these are standard trees, each one will occupy at least a square rod or more of ground, and a dozen trees will need more than twice the land needed for the strawberries,—unless an equal number of *dwarf* cherries are chosen, which would require only about one-fourth the space. Raspberries yield half as good a crop as strawberries, and if each stool occupies four feet square, a rod will contain sixteen plants, and six square rods a hundred, which, if of such varieties as the Doolittle and Orange, will give a copious supply to a family. Currants will yield more; but as they continue longer, the same number, one hundred, may be planted, requiring one-fourth less ground, or three square rods. Two square-rod, planted with New Rochelle blackberries, or two dozen plants, kept in compact form by pinching in, will give a quart or two daily for several weeks, about midsummer. One-sixth of an acre of dwarf pears or a hundred trees, if properly selected and well managed, will afford yearly from fifty to a hundred bushels of fruit, after allowing for occasional death and replacement of trees. An equal supply of summer and autumn apples may be obtained from one-half this ground, if planted with dwarf apples, which are more certain to grow and flourish, and less liable to accidents. Slow-growing sorts may be worked on the Doucan stock, and the stronger growers

on the paradise. This estimate is made on actual experiment, extending through a number of years. Two dozen peach trees, kept well cultivated and properly shortened-in, will give ample crops every favorable season, and need not occupy when thus managed more than twelve feet square each, or about one-tenth of an acre. If dwarf apple trees are omitted, standards for summer and autumn crops, will need four square rods to a tree, and half a dozen trees or a dozen at most, will give abundant supplies in most years for an ordinary family. Twenty-five to fifty trees of winter and spring sorts will usually afford plenty till the small fruits of summer make their appearance.

To recapitulate—the following will be about the required number, cost and area, in tabular form:

|                                 |                   |      |
|---------------------------------|-------------------|------|
| 1000 strawberry plants, on..... | 5 square rods say | \$10 |
| 10 cherry trees.....            | 10 do             | 3    |
| 12 do dwarf.....                | 3 do              | do   |
| 100 raspberry bushes.....       | 6 do              | do   |
| 100 currant do.....             | 3 do              | do   |
| 24 New Rochelle Blackberry....  | 2 do              | do   |
| 100 dwarf pears.....            | 27 do             | do   |
| 50 do apples.....               | 14 do             | do   |
| 24 peach.....                   | 16 do             | do   |
| 12 standard pears.....          | 12 do             | do   |
| 40 do apples.....               | 160 do            | do   |
|                                 | 258               | \$88 |

To which may be added a dozen grapevines, on 5 rods. 263 rods are about an acre and two-thirds—two acres would be ample room. Omitting the 40 standard apples, an acre would more than contain all. In every locality favorable to the growth of fruit, there is no way in which an equal amount of profit, wholesome food, and desirable luxury may be obtained from the same area.

But before going any further it is necessary to discriminate between the effects of good and bad cultivation. The results here pointed out could not be obtained by neglect. Unless the soil is kept clean and mellow; the small fruits generally and the dwarf trees will be an utter failure; and it would be better not to waste the time and labor for setting them. Those who cannot be induced to give proper attention to their trees, should plant the whole ground with apple trees, some of which may possibly live and bear, after a long and feeble growth. The suggestions here made are for the purpose of showing what may be accomplished under good management, and with a view of furnishing, not a mere occasional supply, but an abundance of fresh fruit at all times. Intelligent cultivators will of course alter and modify these numbers, to suit their own local circumstances and preferences.

The third question may be briefly answered, namely, how long after planting may we obtain crops? Strawberries set in spring will bear some the same season, and profusely the second year; dwarf pears, apples, and cherries, the third year and onwards, currants in a year or two, with an increasing amount for several successive years, and raspberries and blackberries the sec-

ond and third year. Grapes and peach trees begin to afford fruit in three years, and standard apple and pear trees in every four or five years, with a regular increase for many years subsequently. The time at which all fruit trees begin to bear will be greatly controlled by the varieties, soil, locality, and treatment received.—*Cultivator*.

## The Dairy.

### How to make Good Butter.

Extract from the report of the Committee on Butter of the Franklin Co. (Mass.) Ag. Society, made at their last winter meeting.

To make the *best* of butter, requires many prerequisites; but for all practical purposes, two main points cover the whole ground, viz., 1st, Neatness; 2nd, Skill. If any dairy-woman expects to make nice butter without the most *scrupulous neatness*, she will find herself greatly disappointed. From the moment when the rich and luscious fluid is first drawn from the cow's udder, to the time when the butter is ready for the table of the connoisseur, the least dirt, the least must or unpleasant flavour in the atmosphere of the room, and the least speck of foreign matter of any kind, must be absolutely and perfectly kept from it, during all its stages of manufacture. In fact, neatness is the *sine qua non* of the butter-maker's art. As well may we suppose that any of the laws that regulate the physical world will be reversed, as to suppose that good butter can be made without the most *scrupulous neatness in every particular*.

The second indispensable qualification of the perfect butter-maker, is *SKILL*—a word of quite extensive signification when applied to this subject. To acquire that skill requires a clear and discriminating judgment, a well educated and experienced mind, and a minute and accurate observance of all the physical laws which regulate the various conditions of the milk and the cream, while undergoing the transformation into butter. To be a successful butter-maker, therefore, requires no inconsiderable degree of education, intellect, and ingenuity. Let us, then, analyze this skill of the butter manufacture, and see what are its most important elements.

To begin, then, we must first have good milk, and to have good milk, we must have good cows, and to have good cows, requires a selection of the best breeds and of the best milkers from the best breeds, for that purpose. But that carries us into another department of agriculture, which we have no time here to discuss.

Assuming, then, that we have good milk, the next thing is to place it in shallow pans, (tin is usually preferred,) and in a degree of temperature neither very warm nor very cold. About 62 degrees Fahrenheit is supposed to be the

state of the air in which cream will rise most perfectly. And here let us remark, that every housewife who aims to make the *best* of butter, should have a thermometer constantly at hand, and should be a frequent observer of its condition.

If milk is kept in a temperature much below 62 degrees, the cream will not rise so rapidly and so perfectly. If kept in a state of the air much above 62 degree, the milk will become acidulated too quickly, and the quality of the cream will thus be injured. Equalization of temperature and a free circulation of pure air, are among the important elements of the butter-maker's skill. The time requisite for cream to rise naturally and perfectly, varies with the temperature, from 24 to 40 hours. As soon as the cream has all risen to the surface, it should be separated from the milk, and with much care; for the less milk that is taken up with the cream, the better will be the butter.

Churning is the next operation, and it is one that determines in no small degree the quality of the butter. If cream is put into the churn in a state much colder than 62 degrees of the thermometer, it will require much more time and labour to convert it into butter, and the butter will never be of as good quality. Let the cream then be brought to an even temperature of 62 degrees, and the often laborious operation of churning, especially in the winter, will become comparatively easy. If the cream is much warmer than 62 degrees the butter will be too soft, too white, and in most particulars, quite poor.

As soon as there is a perfect separation of the particles of the cream which make the butter, from the more watery parts of the milk, let the butter be taken from the churn, and then comes the quite difficult and delicate operation of working over and salting it, both of which require great accuracy and judgment. For if the milk is left and mixed in with the butter, one thing is sure—the butter will never have that compact and smooth appearance that is one of the sure indications of good butter; and what is yet more important, butter left in that condition will not keep long without becoming musty or frowy. Every one then that aims at making the best of butter, must separate entirely the particles of milk from butter, immediately after churning. Washing the butter with cold water is practised by some, but the most skillful butter-makers complete the separation of the solid from the fluid portions by manipular labor alone.

The form in which butter is prepared for the table or for market, is one indication of the skill of the maker. Butter put up in small cakes of oval form, and stamped with a device of flowers, leaves or diamond figures, is the most beautiful, and seemingly adds to the good flavor of the article. In order to sell for the highest price

It should always be put up in that form, or in oblong pieces of about a pound each.

Such are the main requisites of the skilful manufacture of good butter, without which we venture to assert with great confidence, that the best of butter cannot be made.

Does any good housewife, when she has read this report, say "I knew all that before?" If she does, then we ask her with no small degree of assurance, Madam, do you *practice* all these rules for making good butter? If you do, why is it that so large a proportion of the butter that is sent to our markets is so very poor?

HENRY W. CUSHMAN, Chairman.

### The Apiary.

The following remarks on *Foulbrood*, a not uncommon, and often fatal disease among Bees, are taken from "Western Editorial Notices," in the last number of the *Rural New Yorker*.

Bee-keepers, and among them the most eminent, unite in regarding and characterizing Foulbrood as the most grievous evil that affects the apiary. It is doubtless the case that most of your readers—especially such as keep bees, know the character of this dreaded disease among bees, but there may be some who do not.

Dzierzon says there are two kinds of Foulbrood. One is curable and rather innocuous; the other is pestilential and incurable. Both are contagious. The curable kind has this character. The unsealed larvæ die while yet lying coiled on the bottom of the cell, become putrid, and dry up on the bottom into a crust-like substance, which may be easily removed. Such of the brood in the cells intermixed with those diseased, as does not perish before capping, for the most part remains healthy and matures in due time; though it is a fact that exceptional instances of putrid nymphs in such capped cells are found.

The incurable foulbrood is said to be the converse of that described above. The brood does not perish until after it has been capped and begun to undergo its metamorphosis. The putrid mass is not then found at the bottom of the cell, but on the horizontal portion of the cell walls. It is brownish and viscid; and in consequence of the heat of the hive and the admission of the air through a small orifice in the sunken cap, it dries up as a hard black crust which the bees cannot detach, and which they can only remove by totally destroying the cell.

#### INDICATIONS OF ITS PRESENCE.

The author quoted above says, when among a healthy brood a few cells are found here and there, containing a smeary, viscid matter, or a grayish-brown or black, crust-like substance—the dried remains of larvæ or nymphs—it may be regarded as the unmistakable evidence of

the existence of foulbrood. If the larger number of cells are in this condition, this disease must have prevailed in the hive for sometime and have attained an aggravated stage. A disagreeable fetid odor issues from the entrance to the hive, where this is the case.

Colonies affected with this disease do not build new comb in the spring, when other colonies are engaged in such labor, or do so only if they are populous, and pasturage is abundant. If the combs be pressed asunder we shall see that the brood is not placed regularly and uniformly; and on cutting out a piece of such comb, ocular proof of the existence of the disease will be found in the putrid matter contained in the cells.

#### IT IS CONTAGIOUS.

Herein lies its danger; therefore this caution. And I give this caution regardless of the interest of any one who may have long-bitted or any other kinds of bees to sell, and whose apiary may have been, or may be affected by this disease; or who may be near an apiary that is or has been affected. This caution is given with especial reference to such cases. For all these men know that this disease is contagious—that it spreads from hive to hive, and from apiary to apiary; that, once having a foothold, it retains it and extends its influence, if effectual means are not properly taken to eradicate it. The brood is not only destroyed by this disease, but the cells are contaminated and the contagion spreads rapidly thereafter. This disease is known to exist in the Eastern States—is known to have destroyed many large and profitable apiaries—is known to have increased the risk to, and diminished the number engaged in bee-keeping. In some localities this husbandry has been abandoned because of this disease.

The point is, then, that the bee-keepers of the West are in danger of importing it with their importations of Italian bee. For it is well known that these bees, with formidable bills, continue to be sent hither in large numbers, at the rate of five to eight dollars per queen. And with each shipment is usually more or less honey; and with the honey, if it happens to be from infected colonies, comes this foulbrood as sure as fate. Is it not a pretty large risk? When it is asserted that the bee-keeper may convey it from hive to hive, it after performing some operation on a diseased stock he proceeds to work at a healthy one, without first carefully washing his hands and such instrument as he may have been using, it is safe to distrust whatever comes from apiaries that have been affected with this disease.

It is proper for me to say, that I do not write this caution for the purpose of injuring anybody's business, nor with a view to build up any man or class of men dealing in the long-billed bees referred to, but simply to urge that the most rigid care be taken to prevent the introduction of this disease among the apiaries of the West. Bee-

culture has become too large an interest here to allow it to be shipwrecked by the carelessness or recklessness of any man or body of men. The revenue it brings to the Western husbandman is annually increasing. Let it be guarded in this respect.

We pray our Eastern brethren to be careful what they send in response to orders; and let Western men know that they are ordering where they will get only what they want.

#### HOW TO GET RID OF THE DISEASE.

Smother and bury the bees, and burn the hive containing the colony and its contents, as soon as the disease is discovered. There are remedial measures recommended to be taken; but none so efficient and safe if as cheap as the above,

### Wax and Honey.

The prevalent opinion respecting the origin and nature of wax and honey, as expressed in many treatises on bee-culture, and as implied in the definition of the terms as given by the dictionaries, are essentially erroneous. The current impression derived from these sources, is, that wax is contained in the honey or pollen, and is simply extracted by some process in the stomach of the bee; while honey is supposed to be made from the nectar of flowers. Precisely the converse of this is the fact.

1. Wax is a product elaborated by the bees. A simple experiment will suffice to demonstrate this conclusively. If bees be fed with a concentrated solution of loaf sugar and then confined in a box, we shall, in the course of twenty-four hours, find between their abdominal rings thin scales or plates of wax, such as they use in building their combs. Now, probably no one will undertake to maintain that loaf sugar contains wax. It contains only the elementary ingredients of that substance, carbonic acid, hydrogen, and oxygen—which become separated in the body of the bee, and re-combined in different proportions and relations, thus resulting in the formation of wax.

2. It is otherwise in the case of honey. This is in no proper sense the product of the bees, but merely a substance collected by them from the boundless stores supplied by nature.

a. The matter collected by the bees undergoes no change before it is deposited in the cells. The nectar of flowers and freshly gathered honey are, in all their constituents and properties, one and the same substance. Both have a sweet taste and an aromatic flavor. If we sip nectar from the calyx of the honeysuckle, we shall find that it has precisely the taste of freshly gathered honey. When I analysed the wax plant (*Hoya thuya*), which exudes in large drops from the calyx of the flower, I found it was composed of sugar, gluten, and an aromatic substance—which are the constituents of common honey in its pure state.

I fed a colony with a solution of sugar colored with indigo, scented with lavender, and diluted with milk. When the bees had carried this into the cells of a new comb, no difference could be perceived between the contents of the cells and those of the feeding-box—they had the same color, the same taste, and the same smell.

b. If honey or the nectar of flowers remain in the cells, it will in process of time undergo a change. But this change is produced spontaneously, and not by the intervention of the bees, except merely so far as the internal heat of the hive may tend to accelerate it. It results, first, from the gradual evaporation of the aqueous particles contained in the nectar of fresh honey, till a certain degree of consistence is attained; secondly, from the still more gradual dissipation and loss of its agreeable aroma; and, thirdly, from the ultimate conversion of the more saccharine cane sugar, which constitutes an ingredient of the nectar of flowers, into the more insipid grape sugar—a change which all honey undergoes with the lapse of time.

DONHOFF.

### Miscellaneous.

**BENEFIT OF BOOKS.**—The great multiplication of books is sometimes spoken of as an evil, but this is true only in one sense—viz., so far as they are superficial or trashy. When there is a prevalent propensity to authorship, it is a natural incident that there will be a great deal of frivolous writing, or that the same ideas will be often reproduced. The effect of the periodical literature of the present day on the public mind is, in my judgment, not favorable to a muscular tone. Newspapers, literary magazines, and the like, must, in order to please popular taste, consist of light but various material. They are suggestive of many interesting inquiries; but this is of very little value to any but systematic thinkers; and generally the effect is only to distract the mind and impair a habit of consecutive thought. It is true that those who think much are also great readers, even of this fugitive sort of productions. This is partly for relaxation, but also for the new ideas which may be derived from a heterogeneous source, when there is a strong power of assimilation. Such reading may be compared to a conversation of the gossiping kind, which may be supposed to be of no great advantage; yet Sir Walter Scott said he never met with any man from whom he could not learn something in conversation. So of books: it has become almost a proverbial saying that there is none that does not contain something that is valuable. Macauley's History of England indicates an omnivorous habit of mind; materials are turned to valuable account which we should hardly have supposed would have attracted the

attention of any one but a frivolous antiquarian: old songs, obsolete plays, pamphlets, newspapers, traditional proverbs—and these not hunted up merely for the occasion (for that would have been impossible), but constituting a familiar lore. The chief value of Plutarch's Lives I consider to be the affluence of anecdotes, apophyegms and slight incidents, which were condemned by state-ly historians, and which he was compelled to obtain by a process of filtration, involving research into a vast amount of gossiping productions, or what were so esteemed, and had not sufficient merit to reach us, except in the excerpts penned by this most erudite of ancient writers.—A. H. DANA.

**INTRODUCTION OF THE POTATO INTO THE UNITED STATES.**—MESSRS EDITORS.—To answer the inquiry of "A Co. Gent," of New Britain; Ct., as it is put, would be to say that the potato was introduced into America by the Creator "in the beginning" as it is one of the indigenous productions of South America. But the question probably is, when it was introduced into the United States? Answering that question in full will also explain why it is called the Irish potato, as was perhaps the case years ago more than it is now with us, and still is at the South in distinction from the sweet potato.

The only authority I know of in relation to the matter is Belknap's History of New Hampshire, and as the book is not common, I will give, as briefly as possible, the substance of that historian, and if there is further or other information upon the matter, we shall be glad to receive it.

In 1719 a large number of emigrants came to this country from the north of Ireland and settled a township which they called Londonderry. They were called Irish, and there was no little antipathy felt toward them, which would have been very foolish even if they had been natives of Ireland, but they were from a colony of Scotch Presbyterians that had settled in the province of Ulster, Ireland, in the reign of King James I. They had a thirst for civil and religious liberty which their situation in Ulster did not satisfy, and nearly the whole colony removed to America. About one hundred and twenty families came. One hundred families came to Boston, and the rest landed on the coast of Maine. Of the former, about sixteen families were those who made the settlement of the town of Londonderry. The historian referred to says: "These people brought with them the necessary material for the manufacture of linen; and their spinning wheels, turned by the foot, were a novelty in the country. They also introduced the culture of potatoes, which were first planted in the garden of Nathaniel Walker of Andover. They were an industrious, frugal, and consequently thriving people." Hence these people being called Irish, the potatoes which they introduced were called Irish potatoes.—A. B. B., in *Country Gentleman*.

**SCARCITY OF PURE ARABIAN MARES.**—The Arabs' love for their mares, and the jealous care with which such animals are treasured in the East, have formed the subjects of many an interesting story. There is no difficulty in obtaining any number of Arab stallions, for example, of the very purest blood; but it is next to impossible to procure an Arabian mare of very high reputation. A modern writer on the subject tells us that it is even considered a crime to sell one under any circumstances; and in proof of the resolute opposition to the practice, a case is related as having lately occurred in Calcutta, where some Arabian dealers had sold their horses, and in consequence of a heavy bribe one was induced to part with his mare. Some weeks after, when the dealers had already gone homeward, the senior of his party was observed to have returned to the city, a distance of several hundred miles; he lurked about for some days; subsequently it was discovered that he had inquired for the stables where the mare was kept; she was found poisoned, and he had disappeared.

**A RAIN GLASS.**—The following may be depended upon as a rain glass: I have used it for months. Get a common pickle bottle, such as is sold at any Italian warehouse; fill it with any kind of water, to within two or three inches of the top; plunge the neck of an empty Florence oil flask into the pickle bottle. Before rain the water will rise two or three inches in the neck of the inverted flask—often in three or four hours. If the weather is settled for fair the water will remain not more than half an inch high, for days, in the neck of the flask. It never fails to foretell rain; and to-day, July 15, rose as high as the rim of the pickle bottle, in the neck of the flask. It may stand in or out of doors, in sun or shade, and the water never needs changing so long as it can be seen through. Mine is now green through long standing. The oil flask must be cleansed before the neck is plunged into the water. Soda and warm water will cleanse it of oil.—THOMAS ZULLER.—Rose Cottage, Kennington-cross.—*Athenæum*.

**MARAUDING CATTLE.**—Cattle may be educated to do almost anything. A quiet cow may be converted into a skilful jumper in a single season. The first requisite for such training is short feed, resulting from over stocking. The second is low fences; and the third, tempting crops of corn beyond these low fences. In the spring, grass is usually good, corn and other crops are small and uninviting; but during the midsummer periods, when the pasture is dried up, the process often begins. One or two rails are accidentally blown from the fence; the quiet and orderly animals stretch their heads over to reach a morsel of the tall grass; they throw down accidentally two or three more rails, and finally leap over. The owner drives them out

as soon as they have learned the difference between delicious food on one side and short commons on the other, and puts up a rail. They have already learned to leap a little, and the next day they improve and go a rail higher. Another rail is added, and the process is repeated until they become quite expert.—*Country Gentleman.*

**ABD-EL-KADER'S RULES FOR A HORSE.**—The following are the rules laid down by Abd-el-Kader for indicating the points of a horse of pure race. He ought to have three things long, three short, three broad, three pure. The three long are the ears, the forehead, and the fore-legs; the three short are the bone of the tail, the hindlegs, and the back; the three broad are the forehead, the chest, and the quarters; and the three pure are the skin, the eyes, and the feet. He should have the withers high, the flanks fine, not fleshy, the tail well furnished near the root, the eye inclining as if to look at the nose, the forelock full, the nostrils wide their cavities entirely black (if partly white it is a sign of inferiority), the fetlocks small, the hoof round and hard, the frogs hard and dry. He should be able to drink from a stream level with the surface on which he stands without bending the forelegs. The colours most prized are a dark bay or chestnut (the latter esteemed the latest), brown or black. Black are, however, thought less safe on rocky ground; white are considered soft. Roan, dun, and iron gray are little esteemed. A blaze, if all down the face, is approved, so are three white legs; but the rules on this matter are very fanciful. All these doctrines are supported by an infinity of proverbs, poetical quotations, and religious maxims, but it will be seen that they accord generally with our own ideas. Much importance is attached to a well lying shoulder; and to breadth of chest, both as a security against interfering and as giving room for the lungs. A practical rule for recognising the development of the forehead is to measure the distance from the extremity of the bone of the tail, along the back to the centre of the withers, then from that along the neck and crest, down the face to the upper lip. If the two measurements are equal, the horse will prove good, but of middling speed. If the length is greater behind than before, the animal wants power. If it is greater before than behind, he is excellent, and the difference in measurement the greater his superiority. The count d'Aure, late chief of the School of cavalry, and now inspector-general of the imperial studs, assures Gen. Daumas that he has tested this rule in more than a hundred cases, and found it unailing.—*London Review.*

**SIR ISAAC NEWTON AND HIS CATS.**—A human being weighing a general principle, must call up before his mind all that is to be said for and against it. And he may quite overlook some

important reason, on one side or other. He may quite forget something so obvious and familiar, that a child might have remembered it. Or he may fail to discern that some consideration which mainly decides his judgment is open to a fatal objection which every one can see is fatal the instant it is stated. Was it not Sir Isaac Newton who had a pet cat and kitten? And did not these animals annoy him while busy in his study, by frequently expressing their desire to be let out and in. The happy thought struck him that he might save himself the trouble of often rising to open his study door for their passage by providing a way that should always be practicable for their exit or entrance. And accordingly the great man cut in his door a large hole for the cat to go out and in, and a small hole for the kitten. He failed to remember what the stupidest bumpkin would have remembered, that the large hole through which the cat passed might be made use of by the kitten too. And the illustrious philosopher discerned the error into which he had fallen, and the fatal objection to the principle on which he had acted, only when taught it by the logic of facts. Having provided the holes already mentioned, he waited with pride to see the creatures pass through them for the first time. And as they arose from the rug before the fire, where they had been lying, and evinced a disposition to roam to other scenes, the great mind stopped in some sublime calculation; the pen was laid down; and all but the greatest man watched them intently. They approached the door, and discerned the provision made for their comfort. The cat went through the door by the large hole provided for her, and instantly the kitten followed her *through the same hole!* How the great man must have felt his error. There was no resisting the objection to the course he had pursued, that was brought forward by the act of the kitten. And it appears almost certain that if Newton, before committing himself by action, had argued the case; if he had stated the arguments in favour of the two holes, and if he had heard the housemaid on the other side, the error would have been averted.—A. K. H. B. in *Good Words.*

**THE GREAT GREY SHIRKE.**—Fierce and powerful as this bird is, it holds the falcon in the greatest terror, and is gifted with so true an eye for its enemy, that it can perceive a falcon when at an immense distance. Taking advantage of this peculiarity, the fowlers who set their nets for falcons always take with them a grey shrike, and after setting their nets, fasten the string to which the bird is tied to a peg near the nets.—A little turf hut is built as a place of refuge for the shrike, and a small mound or hillock raised, on which it perches. The fowler then retires to his own little hut, places the strings which draw the net within reach of his bird,

and watches the shrike out of a small window which commands the mound where it is perched. Feeling secure that the shrike will not suffer a hawk to come within sight without giving notice, the fowler takes out his netting or other sedentary work. Hundreds of birds may pass over the net without the shrike giving the least alarm, but as soon as it can see a falcon, it flutters about, gets uneasy, and at last begins to kick and squall with terror. Roused by the sounds, the fowler jerks some strings communicating with perches on which living pigeons are perched, and the flutter thus occasioned attracts the falcon's attention, and induces him to stoop for a prey that appears so easy. As the foe approaches nearer, the shrike's terror increases, and as the falcon swoops at the pigeons, the shrike screams for fear and runs for shelter under the tiny hut. The movement is a signal for the fowler, who draws the strings of his net and then closes the falcon as he makes his dart on the pigeons.—*Routledge's Illustrated Natural History.*

**TAKE CARE OF YOUR HARNESS.**—More damage is done to a harness during the rainy weather of early and late winter, than during all the rest of the year. Saturated with water covered with mud, and often frozen stiff, so as to almost break when bent, in necessary handling. Unusual care should be taken to keep it well oiled and hung up in proper shape when not in use. Thus treated, it will not only last many times longer, but look infinitely better than when neglected in the usual manner. As to the kind of oil we know nothing better than neat's foot or the daubing used by tanners. To give the black color characteristic of new leather, a little lamp black may be added, without detriment, though it is better not to use this second going over. Before putting on the oil, however, there are two important considerations which must be observed—cleanliness and dampness. The necessity of the first is obvious, and the last is not less important, since the oil cannot penetrate the leather and make it soft and pliable if put on when it is dry and hard. One of the best ways to give the leather the required degree of moisture is to wrap up the several parts of the harness in wet cloths previous to oiling. But this trouble is unnecessary where washing has been resorted to for cleaning, as the oil may be applied before the leather is entirely dry. The oil should be rubbed in briskly with a brush or cloth, so as to ensure its absorption. Varnish should never be used as it closes the pores and renders the penetration of the oil more difficult. Vegetable oils are hardening in their effects and should never be used for that reason. Finally let the application of oil be as frequent as needed, not once a year as is the rule with some, or almost never, as is the practice of many.

**EVIL NOT A NECESSITY.**—As surely as God is good, so surely there is no such thing as neces-

ary evil. For by the religious mind, sickness and pain, and death are not to be accounted evils. Moral evils are of your own making; and undoubtedly, the greater part of them may be prevented. Deformities of mind, as of body, will sometimes occur. Some voluntary castaways there will always be, whom no fostering kindness and no parental care can preserve from self-destruction; but, if any are lost for want of care and culture, there is a sin of omission in the society to which they belong.—*Robert Southey.*

### Death of the Hon. Adam Fergusson.

It is our painful duty to record the death of this estimable gentleman and distinguished agriculturist, which took place suddenly, September 24th, at his residence, Woodhill, near Hamilton. For the last two years Mr. Fergusson was unable to take any active part in public life in consequence of an attack of paralysis, but he was not incapacitated from inspecting the operations of his farm, and, what he always took a particular liking in, the progress of his live stock, and the quiet enjoyment of the company of a friend.

Mr. Fergusson was a native of Scotland and descended from a family of great respectability and influence. He studied for the law in the University of Edinburgh, and became a writer to the signet. Having however a strong propensity for country life, and coming into possession of landed property, he soon distinguished himself as an earnest student and promoter of agriculture. We have often heard him relate the pleasure and advantage he derived from the lectures of Dr. Coventry, the first professor of agriculture in that distinguished seat of learning, also from those of Professor Dick, the founder of the world-renowned veterinary school of Edinburgh. Mr. Fergusson also spent some time with two or three extensive farmers and breeders in the counties of Northumberland and Durham, where he formed an acquaintance, which ripened into an intimate friendship with that celebrated agriculturist John Grey, Esq., of Dilston, extending over a lengthened period of more than half a century. It was

here that Mr. Fergusson acquired a taste for Durham Cattle, or, as they are now usually called, "improved short horns;" a department of husbandry to which he devoted himself with distinguished success, both in Scotland and in Canada.

In 1831, Mr. Fergusson came to Canada, and purchased an extensive tract of wild land in the Wellington District, now forming the flourishing and well-farmed township of Fergus. His clear and penetrating mind foresaw the advantages which that part of Canada even then offered to enterprising industry, and he accordingly wrote a series of letters, which were published by Messrs. Blackwood of Edinburgh, a book that elicited much enquiry and conveyed valuable information to such as were seeking new homes in the then literal wilds of Canada. In 1842 he was appointed by the Crown to a seat in the Legislative Council, where by his frank and straightforward course he commanded the respect, if not the confidence, of all parties. In 1846, Mr. Fergusson, in connection with Colonel E. W. Thomson, and a few others, succeeded in forming the AGRICULTURAL ASSOCIATION OF UPPER CANADA; the first exhibition of which was held in Toronto, in the fall of that year; Mr. Thomson, with whom the idea first originated, being President, and Mr. Fergusson delivered the Address. Of that association from its commencement to the period of his death, he was a constant and zealous supporter. He was also a member of the Board of Agriculture from its formation, and the originator of a scheme for giving to young farmers sound practical instruction in the veterinary art, with an ultimate view of establishing in Upper Canada, a veterinary school; a project that has already been commenced by Mr. Smith, a licentiate of the Edinburgh college, under the patronage of the Board of Agriculture.

Mr. Fergusson was one of the oldest members of the *Highland and Agricultural Society of Scotland*, having been elected, we believe, as early as the year 1806. He was among the first to introduce pure bred cattle into this province, and he always had, to the day of his death, a select herd of Short horns, a breed to which he was, we may say, enthu-

siastically attached; and for the dissemination of which he had bred and sold upwards of sixty male animals, exclusive of cows and heifers. Among the many proofs of his ardent love of rural improvement, particularly of cattle, it may be mentioned that he gave annually a silver cup, and two medals, the former for the best grade cow from a Short horn bull, and the latter for the two best pair of Domestic Fowls, exhibited at the Provincial Show.

Our good and venerable friend has been removed from a sphere of action, which by his virtues he adorned, and blessed. The writer of this hasty notice had the pleasure of spending a day with him at his picturesque retreat, Woodhill, only a fortnight before his decease, and found him as usual full of desire and hope in the great work of agricultural and social improvement. He was looking with anxious interest to the results of our forthcoming Provincial Show, during the holding of which he was summoned to another and, there is good reason for hoping, a better world. The members of the Provincial Agricultural Association gave expression, at the annual meeting on the show ground, to their esteem for his memory, by passing in solemn silence an appropriate resolution. Mr. Fergusson had entered, we believe, on his 79th year. The memory of the just is blessed.

#### FOR SALE!

**Ayrshire Cattle, Leicester Sheep, and Berkshire Pigs.**

THE Subscriber offers several Young Bulls, Heifers and Cows, on very Liberal Terms. Specimens from his *Prize Herd* will be on Exhibition at Toronto, if all's well.

P. R. WRIGHT, Cobourg, C. W.

Aug. 30th, 1862.

6-mos.

#### THOROUGH-BRED STOCK FOR SALE.

THE Subscriber has for sale DURHAM and GALLOWAY CATTLE, LEICESTER, COTSWOLD, and LINCOLNSHIRE SHEEP, Male and Female 10 Durham and Galloway Bull Calves—price from \$100 to \$200; 30 Shearling Rams, weighing from 230 to 285 lbs. each—Price from \$50 to \$100 each.

JOHN SNELL,

Edmonton P.O., C. W.

Four miles from Brampton Station G.T.R.

## Horse Infirmary and Veterinary Establishment, Corner of Bay and Temperance Streets, Toronto, C. W.

A SMITH, Licentiate of the Edinburgh Veterinary College, and Veterinary Surgeon to the Board of Agriculture of U. C., begs to return his thanks to the Public generally for their support since opening the above mentioned establishment, and respectfully solicits a continuance of the same.

And also begs to announce that Veterinary Medicines of every description are constantly kept on hand:—Such as, Physic, Diuretic, Cough Cordial, Tonic Condition, and Worm Balls and Powders. The constituents composing the Cough-balls, have been found (by Professor Dick, of Edinburgh) most serviceable in alleviating many of the symptoms of Broken-wind or Heaves in Horses. Colic Draughts, &c., a mixture which owners of Horses should always have beside them.

Liniments for Sore-throat, Sprain, Curb, Spavin, Ringbone.

Blistering Ointments. Liquid and sweating Blisters.

*Horses bought and sold on commission.*

Toronto, Aug. 30th, 1862.

## TO BE SOLD BY AUCTION,

*On Thursday, Oct. 16, 1862,*

THE well-known Herd of NORTH DEVON CATTLE, consisting of more than forty head of Cows, Bulls, and Heifers; one hundred and seventy West and Southdown Ewes and Rams; pure blooded Essex Pigs, in pairs fit for breeding.

Catalogues of description, with pedigrees, may be had fourteen days before the sale, on application at the office of the *Galt Reporter*, if by letter, prepaid. Credit of 12 months may be had on approved endorsed paper.

## THE SPLENDID FARM,

Consisting of upwards of THREE HUNDRED ACRES, to be sold by private bargain, on accommodating terms.

DANIEL TYE.

County Waterloo, Wilnot, August 1862. td

## BOARD OF AGRICULTURE.

Office in the New Agricultural Hall, corner of Yonge and Queen streets, Toronto.

HUGH C. THOMSON,

Toronto August, 1862.

*Secretary.*

OF UPPER CANADA.

VOL. XIV.

TORONTO, NOVEMBER 1, 1862.

No. 21.

## Hints for November.

The agricultural year in this part of the world may now be considered almost closed. What little remains to be done consists in finishing the getting up and storing away of root crops, a work that should now be completed without delay. Ploughing should be proceeded with as long as the ground continues unfrozen, and every effort made to give a finish to the operations of the farm before stern winter finally sets in. The severe and protracted drought of the spring and early portion of summer seemed at the time almost to annihilate the farmer's hopes, but in consequence of subsequent rains and genial temperature the result of his labors and care has far exceeded the most sanguine expectations. In many parts of the Province the crops in general have proved abundant, and in none has any thing like a failure been experienced; a circumstance that imperatively calls for gratitude to the bountiful Giver of all good.

The farmer in this climate, whatever perseverance he may have exercised, always finds enough to do at this season to bring his operations to a proper and satisfactory conclusion by the time that the advent of winter actually takes place. Too many have not safely stored their roots or completed as much ploughing as is desirable before that imperious master—frost—puts a stop to most out of door operations. The ploughing deeply, and however roughly heavy land, so as to expose the largest amount of surface to the action of frost and snow, produces a vast benefit

on the soil in a chemical as well as mechanical point of view, and materially diminishes the labour of spring in procuring a suitable seed bed for next year's crops. On some soils autumnal ploughing will save at least twenty-five per cent of spring labour, besides the enriching of the land without any outlay to the farmer. The soils least benefitted by these means are such as are naturally loose and sandy, the particles of which will often run together before the time of spring seeding, and become almost as compact as though they had not been operated on with the plough.

Another subject demands the farmer's attention at this season, namely the scouring, when necessary, of surface drains. Before the setting in of winter all obstructions to be found in ditches and open furrows should be removed, that the large amount of water occasioned by the melting of the snow and the rains of spring may readily find an exit, and thus present the serious injury so often seen done both to the soil and the young crops by the action of stagnant water. Winter wheat is often seriously injured from negligence in this matter. At present, and in the nature of things it must in a new country continue so for some time to come, the surplus of our fields is often very irregular and uneven, and the water which accumulates in the depressions of our fields, proves highly detrimental to the cultivated crops. Underdraining and getting a smooth surface must necessarily be the work of time, involving too

much thought, labor, and expence. But it is obvious to every observer of rural affairs how much is commonly neglected to be done, that might have been accomplished without involving much, either of time or outlay. A man with a spade, if nature or art has provided an outfall, may often in a few hours relieve large portions of a field of most if not all of their stagnant surface water, by deepening at places the furrows made by the plough, or such portions of the ditches or natural drainage as are too shallow or partially obstructed. Wheat fields should be carefully examined with this object in view before the ground becomes permanently frozen. This would be a cheap way of benefiting both the soil and the crop.

Stables, byres and yards should be now examined and such repairs effected as are necessary for the production and thrift of live stock, which frequently suffer as much from wet and cold draughts as from irregular and inadequate feeding. The farmer should always bear this truth in mind, that all our domesticated animals thrive better on a smaller amount of food when kept dry and warm, than with a larger quantity however nutritious, under opposite conditions. Notwithstanding the shortness of the hay crop, what with the abundance and quality of straw and roots, cattle if properly protected, kept clean and dry, and regularly fed, may be carried through the approaching winter in a healthy and improved condition. The greatest care should now be taken that chaff, straw, &c., be properly husbanded, and that turnips, carrots, mangels, &c., be secured stored away so as to be available for use not only through the winter, but a portion reserved by what is often as pinching a time as any, early spring.

### The Wire Worm.

*To the Editor of the Agriculturist.*

DEAR SIR,—Permit me, through your paper, to inquire of you and your readers the best means to be adopted in order to destroy the wire-worm, or at least to prevent its ravages, or if there are any means of doing so.

My crops have for the last few years been almost totally destroyed by it; and the wheat which is now growing on my farm, in one field more especially, is being cut off very fast by it, so much so that I believe it will be all, or nearly all, gone before the frost sets in, and to plough it up to sow spring wheat, barley, &c., believe would be useless, as such would in all

probability share the same fate. I have tried many ways to banish it without effect. Different ways and plans have been suggested to me by various individuals, some towards its eradication, and some again as a means only of preventing it working at the wheat plant. Some of these I have tried which I found to be of no service. Now, for general information, I submit to you the following, all of which I have heard and seen recommended:—First, the propriety of rolling the wheat in the fall and spring with a heavy metal roller. Second, the propriety of ploughing in the fall and summer, following the next season, keeping the land clear of weeds, &c. Third, propriety of sowing lime, salt, or soot. Fourth, the propriety of growing buckwheat on the fallow, and ploughing it down when in bloom. Fifth, the propriety of sowing soda-ash a short time before sowing the wheat.

With respect to the first question, rolling, I have heard it mentioned as a means of preventing the worm injuring the wheat; in fact I have heard some of my neighbours who have tried it say that such entirely stopt its progress. How this can be the case (if it is so) seems a mystery to me. It may be in consequence of the soil being pressed tightly together and being made hard about the roots of the plant. I have noticed that the looser spots in the field are always worse affected than the harder ones.

As to the second question—ploughing in the fall, &c.—suggested as a means of starving the worm out, I have ploughed in the fall and found it to be of no service to spring crops, that is as far as the worm is concerned, for the barley and the spring wheat which I sowed on it were as much destroyed as on a piece in the same field which was not ploughed until the spring. But summer-fallowing the next season, after the fall ploughing, may starve them out; and would it not be a good plan, after summer-fallowing, instead of sowing fall wheat, to let it stand over and sow spring wheat? By that means a person could give it a second fall ploughing without much loss.

As to the third question—sowing lime, &c.—some recommend one and some another of these.

As to the fourth—growing buckwheat—I have tried this without effect, but the buckwheat was a poor crop, which may account for the failure.

As to the fifth—sowing soda-ash—I have seen it highly recommended in a Belfast news paper as being an effectual cure.

By answering the above questions, or making any suggestions that may be beneficial towards the eradication of this pest—wire-worm—you will confer a great favour on your humble servant, and let me know by what means, if there are any, I could save the crop which is now in the ground. Any information from you or any of your readers on this topic will be thankfully received.

By giving the above an insertion in your paper you will much oblige,

Yours, &c., AGRICOLA.

Chinguacousy, 27th Oct., 1862.

[We are not acquainted with any specific or absolute method of exterminating the wire-worm, that will be effectual under all circumstances. Most of the means mentioned by our correspondent, although they appear to have failed with him, will, one or other, be found generally to *mitigate* the ravages of this destructive pest. Our correspondent's case appears to be an extreme one, and nothing less, perhaps, than the burning of the soil, will effect a thorough cure. Old pastures, when broken up, are peculiarly liable to have their cultivated crops, for several seasons, injured, and sometimes totally destroyed by the wire-worm; and this is not unfrequently the case on badly tilled land abounding in weeds, on the roots of which, as well as those of cultivated crops, the larva of this beetle finds a subsistence. Several expedients for destroying it in gardens may be readily applied, and with, to a great extent, certain success; such as burning, deep and frequent digging, hand-picking, &c., appliances generally too expensive and tedious on a large scale. In raising hops in England, it is not uncommon to put around the hills in spring the first year after planting a few cut potatoes, for which the wire-worm has a particular liking. These potatoes are taken up, and, if need be, others planted, every few days. In this way count less numbers of the larvæ are captured, and the roots of the young hops preserved. Our correspondent will find in the 12th volume of the *Agriculturist* for 1860, pp. 29, 46, 64, an essay on the wire-worm, treating the subject somewhat in detail. We shall be happy to hear from any of our readers who have had experience of, or made observations on this matter, and shall be happy to embody their remarks in a future article or articles at the earliest opportunity.—Ebs.]

### Short-Horns as Show Stock.

A disposition to lay on fat rapidly, leading to a more than usually early maturity, is a prominent feature in the improved short-horn. This desirable quality is, however, often grossly abused, especially in the case of stock intended to compete at the principal shows. The practice may have originated, perhaps, in a desire on the part of breeders to prove the extraordinary fattening properties of the breed at a time when it was fighting its way into public estimation, and when it had to contend against prejudices in favor of other established breeds.

Whether this supposition be correct or not, it is at least a well-known fact that almost every person who intends to show his short-horns in public considers it necessary to prepare them for exhibition in a very different manner from the course which would be followed were the animals to be kept at home solely for breeding purposes. A very liberal milk diet is supplied in the case of young bulls and heifers for many months after they would have been weaned under ordinary circumstances; and not only are they amply provided with that very nourishing description of food, but they are also crammed with cake, boiled barley, malt, even double X, and in short, every kind of food which is calculated to swell out their proportions, and cover every point with flesh and fat. A similar system is pursued in the case of older stock, and thus the "breeding classes" at our shows usually present an array of animals which would fill appropriately the stalls at a Christmas exhibition, but which are sadly out of place when shown as "breeding" animals. We have frequently seen butchers, in a mixed show of breeding and fat stock, selecting the cow or heifer which had been awarded the gold medal as the best of all the breeding animals as being the fattest animal in the show, far excelling, in a butcher's estimation, any of those which had been avowedly prepared for slaughter.

We emphatically protest against a system of judging which awards prizes to "breeding animals, forced into such an unnatural state as this—forced until it becomes absolute cruelty for any one to insist on their being made to stand up even for a few minutes—until their ungraceful, waddling, hobbling gait, on being led out, produces painful feeling in the minds of spectators, instead of the unqualified admiration which might and ought to be elicited. And such decisions deceive no one—none, at least whose opinion is worth having. The ticketed and be-ribboned monsters may call forth the empty praise of those who poke at them with daintily gloved fingers or with the point of natty parasols, simply because poking of some sort or other is supposed to be essential in the examination of every prize animal; but the real Simon Pures look on with a very qualified degree of admiration; and whilst they certainly contemplate with interest the well-covered ribs and loins, the overhanging rumps, and the general state of obesity which, like charity, covers perhaps a multitude of faults, ask one another, with a very doubtful air, "Will they breed?" Ay, that's the rub; will they breed?

Now for a practical reply to this very practical question. Year after year and show after show, prizes are withheld from animals in the breeding classes, simply because those animals have not fulfilled the conditions. To speak in technical phraseology, they have not "qualified." They have proved barren—barren of produce, at least, though not of fame, to their owners.

They stood first at such and such Royal Shows—such is the record in aftertimes; but the fact that they were subsequently deprived of any permanent token of their honours, owing to their barrenness—their artificially created barrenness—is studiously kept out of sight. But, although the money prize has not found its way into the purse of their owner, nor is the medal producible, their temporary honour serves as an advertisement for other, perhaps inferior but more useful, animals of the same herd, and the value of the latter becomes heightened in consequence of their relationship to the winners. That is the secret. Forcing for show purposes is only a mode of advertising the excellence of the owner's wares; for short-horn breeding is quite as much a trade as shoemaking or tailoring; and though in some respects a costly mode of advertising, still it pays, and pays well too, in certain cases. Of this we have a clear example in the success and high standing of the Warlabby herd; for, without attempting for a moment to detract from the unquestionable merits of the Warlabby short-horns, we may be permitted to doubt whether Mr. Richard Booth would ever have enjoyed—and long may he enjoy—his comfortable income of £5,000 a year from the hiring of his bulls, were it not that he regularly sacrifices some of his best females to the absurd necessity which exists of overforcing for royal show exhibitions. And perhaps this very circumstance proves more than anything else the extraordinary excellencies of the Warlabby short-horns. Mr. Booth's females are crammed for show purposes, and sacrificed in consequence as breeders; and yet the standing of the herd is kept up by breeding from what may be called, comparatively speaking, the very weeds of the herd. Such being the case, the reflection naturally arises in one's mind. What would that herd become, and to what pitch of excellence would it arrive, were show judges invariably to act as they would do while purchasing for themselves, and, by their uniform rejection of all animals unfit for breeding in consequence of overforcing, encourage a feeling in favour of natural condition, and thus save the lives, and secure the usefulness, of those wonderful short-horns which are annually sent forth from Warlabby? If the éclat conferred by even nominal success at a Royal Show pays Mr. Booth, and atones for the loss of usefulness on the part of the prize females of his herd, we cannot, nevertheless, consider it in any other light than a national loss, when the flowers of such a herd are compelled to be sacrificed in order that they may attain a certain standard of excellence, which is never taken into consideration, and is even scrupulously avoided, at any other time than at a show, or believed to be desirable in any save show animals.

It is not because Mr. Booth is a sinner above all others in respect to overforcing his short horns that we thus allude to him. It is because

he is—to use the designation applied to him by his fair and enthusiastic disciple, Lady Pigot—"the hero of short-horns;" because when we speak of "Booth blood," we refer to the most successful line of short-horn blood in existence; for the majority of winners at all the shows in the kingdom have Booth blood in their veins; and for these and other reasons we hold it to be a national loss, as we have said, when such a man as Richard Booth must yield to a fatal and absurd passion, whenever he chooses to become an exhibitor, and by doing so deprive the country of the advantages which would follow to remain in a natural state, so as to transmit their peculiar excellences through a line of healthy and prolific descendants.

But although it may, perhaps suit Mr. Booth and a few other breeders to run great risks, it does not suit everyone to follow their example. And it is because many have tried to do so when they had not the right stuff nor the same advantages to fall back upon that we find in short-horn history so many instances of what we must call disappointed ambition, and of temporary success followed by sudden and utter extinction. All who are acquainted with such matters know that many individuals have attempted to become eminent short-horn breeders and exhibitors, and failed in the attempt. They have gone to great expense, without much judgment as to the materials they were collecting for the foundation of their future herds; they have forced their show stock, and they have sometimes even got a prize or two; but the very expensive cost of their whistle has ultimately sickened and frightened them, and they have abandoned the pursuit in disgust. Now, if those people had chosen to rest contented with moderate expectations, to have gone quietly and reasonably to work, it is most likely their efforts would ultimately have proved serviceable to the community and profitable to themselves, instead of leaving them in such a position as to act merely as beacons, to warn others of the rock on which they made shipwreck.

For all these evils there is a remedy, and we feel convinced it is high time it should be applied. Let it be perfectly understood that judges at our royal shows are resolved to reject every animal which comes before them, no matter how superior that animal may be in other respects, provided it is shown in such a state from forcing as to render its qualification, as a breeding animal doubtful. Let this rule be firmly and uniformly acted upon, and there will be no more forcing, the finest and, therefore, no more sacrifices of cattle in the world. For breeders who are exhibitors do not follow the practice because they like it; they have no desire to do so, but they have no option. They must either force or stay at home. There is, no doubt, a regulation in the programme of our principal societies to the effect that judges are expected

to disqualify animals which do not appear to be in a fit state for breeding purposes; and in the cow classes it is expected that "a live calf" shall be produced within a certain period after the prize has been awarded. But both regulations are often a dead letter, and might as well be omitted altogether for all practical purposes. Judges look to condition, and favor it; and the "live calf" may only have had sufficient strength to draw a single faint and almost imperceptible breath ere its existence terminates—a finale attributable solely to its dam's unnatural and unhealthy "condition."

It is necessary that show regulations should contain a proviso of the nature we have mentioned, but it must be evident that everything depends on the judges as to the manner in which a regulation of this nature shall be carried into effect. We do not mean to say that judges do not act conscientiously under the circumstances when they give prizes to over-fed animals; but we do mean to say that in doing so they act very differently from what they would do were they making a selection for their own use and advantage; and all we ask is, that they would act for the public as they would be for themselves. Let them do as they would be done by. For what is the object of their appointment as show judges? It is to tell the public which are the best animals for breeding purposes out of a number brought under their notice; and it appears passing strange that they should select as patterns the very fattest, as they almost invariably do, or at least, with comparatively rare exceptions: whilst all the time they would never think for a moment of keeping their own regular breeding cattle—male or female—in anything like similar condition. It is in this very point that the absurdity of the present system of judging lies; it is founded on a most vicious and ruinous fashion, and we decidedly think that the judges, who are breeders, should set their faces against it for their own credit, whenever an opportunity offers, and thus confer an inestimable benefit on all concerned.

Nor need we be afraid that the interest felt in our shows would be lessened were natural condition encouraged, instead of being discouraged as it is at present. We entertain the opinion that our show catalogues would present a much greater array of entries, and that the effect of encouraging natural condition would be to bring out many first-rate animals, of the existence of which the public are scarcely aware, as these are at present kept at home, because their owners prefer that they shall be sure and regular breeders, rather than prize winners followed by infertility, or at least great uncertainty as to whether they shall afterwards perpetuate their kind or not.

It is not, however, in the short-horn sections alone that the evils of enforcing are evident. Hereford breeders are equally culpable, and, in fact, with the exception perhaps of West High-

lands, Ayrshires, and Alderneys, it is questionable if there are any of our British breeds which have not suffered more or less from that practice. We have all heard of short-horn cows and heifers being shown and winning at Christmas shows of fat stock, and then, instead of being handed over to the butcher, as one would anticipate from their appearance on occasions of this kind, taken home and shown next summer in the breeding class of a royal show, and we have considered such proceedings as savouring somewhat of the preposterous, but we have also known precisely the same thing done in the case of heifers of the Angus breed. And when we go into other classes of stock, into the sheep and swine sections of our shows, the same forcing system is found to prevail, and the decisions of judges in such cases are just as liable to be influenced by "condition" as in the short-horn and other cattle classes. It is, in short, a general as well as a crying evil; the great blot on an otherwise commendable "institution"—that of public competition; and it is satisfactory to know, therefore, that public feeling is decidedly in favour of its entire and immediate abolition; "a consummation," no doubt, "devoutly to be wished," but which depends wholly on the managers of our royal shows, and our royal show judges in all departments.—*Journal of Highland Society.*

#### Experiment to Test the Profitableness of Various Kinds of Sheep.

A very interesting experiment, to test the fattening qualities, as well as the profitableness, of various kinds of sheep, has just been brought to a conclusion at Millhill, Inchtute, by Mr. McLaren, factor to the Right Hon. Lord Kinnaird. The sheep selected to be operated upon were Col. Inge's breed of Leicesters, Lord Kinnaird's breed of the same sheep, Mr. Hardie's border Leicesters, and Lord Kinnaird's Greyfaced Cotswolds. Ten of each variety were chosen, and the experiment extended over twelve months. Unfortunately, the season was very unpropitious, the continued wet inducing foot-rot in many of the animals, which occasioned the death of some and threw others very far back—so far, indeed, that several of them were a good deal heavier two or three months before the experiment was completed than they were at its termination. Those dying had to be replaced by others not equal in points of weight or excellence, so that the test, so far as the whole ten in each lot are concerned, is not so absolutely perfect as could have been wished, though quite as correct as it was possible, under the adverse character of the weather, to make it. No doubt, it is almost of equal importance for farmers to know the hardiest kinds, or which will stand best an exceptionally moist season like that which we have just experienced.

ed. But that is a question which we do not at present propose to discuss. We pass over also all reference to the weight of the fleeces, and we do so the more readily as we understand that Mr. M'Laren, whose admirable practical essays have more than once secured the Highland Society's premiums, will supply an elaborate paper on the whole subject to the *Transactions* of that society. In the meantime, we doubt not the readers of the *Scottish Farmer* will be glad to learn the result so far as it relates to consumption of food and fattening alone. In order to show as nearly as possible the true fattening properties of the several varieties of sheep, we shall take only four out of each lot of ten, these four having kept almost, if not quite, free from the rot during the whole of the time that the experiment lasted.

Beginning with Colonel Inge's Leicesters, we find that four of these consumed on the average, in the course of the year, 2,122 square yards of grass, 932 lbs. of clover, 10,799 lbs. of turnips, 1,144 lbs. of mangels, 200 lbs. hay, 74 lbs. of chaff, 53 lbs. of Indian meal, 6 lbs. of Indian corn, 528 lbs. of cake, and 365 lbs. of oats. The four sheep at the beginning of the experiment weighed respectively, 88 lbs., 86 lbs., 86 lbs., and 86 lbs.; at the finish they weighed 160 lbs., 159 lbs., 161½ lbs., and 159 lbs., showing on an average, a gain in live weight of nearly 74 lbs. each, or a total gain of 295½ lbs., which, say at 6d. per lb., would yield at £7 7s. 9d.

Four of Lord Kinnaird's Leicesters consumed 2,084 square yards of grass, 780 lbs. of clover, 10,479 lbs. of turnips, 1,178 lbs. mangel, 214 lbs. of hay, 76 lbs. of hay chaff, 53 lbs. Indian meal, 6 lbs. Indian corn, 451 lbs. cake, and 365 lb. oats. The live weights of each at starting were as follows:—75 lbs., 84 lbs., 80 lbs., and 81 lbs. At the conclusion they were 164 lbs., 146½ lbs., 155½ lbs., and 164 lbs. There was an average gain in the weight of each of 77½ lbs., or, on the whole four, of 309 lbs., at 6d. per lb., as before, £7 14s. 6d.; showing a gain of 6s. 9d. over the other lot. But this positive gain does not represent all the advantage Lord Kinnaird's Leicesters possess over their more thoroughly English neighbours. They acquired this at a smaller consumpt of grass, clover, turnip, and cake. To ascertain, then, the real superiority of the one over the other, our readers must debit Colonel Inge's Leicesters with 38 square yards of grass, 152 lbs. of clover, 300 lbs. of turnips, and 77 lbs. of cake, which they consumed over and above Lord Kinnaird's variety; and the latter with 34 lbs. of mangels, 14 lbs. of hay, and 2 lbs. of hay chaff which they eat more than Colonel Inge's. We do not put a money value on these things, because the prices varies much in different districts, and because each reader can easily do that or himself in accordance with the prices in his own locality.

We now come to Mr. Hardie's Leicesters—the Scotch or border Leicester, as they are

called. Four of these consumed 2,235 square yards of grass, 1,010 lbs. of clover, 12,093 lbs. of turnips, 1,229 lbs. mangels, 250 lbs. hay, 70 lbs. hay chaff, 53 lbs. Indian meal, 6 lbs. Indian corn, 529 lbs. cake, and 365 lbs. oats. At the commencement, these sheep weighed respectively, 91 lbs., 90 lbs., 92 lbs., and 93 lbs.; and at the finish, 198 lbs., 181 lbs., 188 lbs., and 182 lbs., showing an average increase on each of 95½ lbs., or on the whole, an increase of 383 lbs., which, at 6 per lb., would return £9 11s. 6d. This is a gain over Lord Kinnaird's, so far as mere butcher's value is considered, of £1 17s.; but then the greatly increased consumption of Mr. Hardie's lot reduces, very materially, the apparent profit. They eat 151 square yards of grass more, 230 lbs. of clover, 1,614 lbs. of turnips, 51 lbs. of mangels, 36 lbs. of hay, and 6 lbs. of cake. In other words, as much more grass as would have kept a third of a sheep of Lord Kinnaird's breed, as much more clover as would have kept one sheep and a fifth, as many more turnips as would have kept three-fifths of a sheep, as much more mangels as would have fed the sixth of a sheep, as much more hay as would have fed two-thirds of a sheep, and as much more cake as would have fed five-sevenths of a sheep. Speaking approximately, this experiment shows that about five of Lord Kinnaird's sheep could be kept on the same quantity of food that is needed for four of Mr. Hardie's. The gain in meat of these five sheep would fully equal Mr. Hardie's four, while the fleece of the fifth sheep would make his Lordship's more profitable than the others.

The grayfaced Cotswold consumed 2,182 square yards of grass, 1,050 lbs. of clover, 12,533 lbs. of turnips, 1,442 lbs. mangels, 254 lbs. hay, 86 lbs. hay chaff, 53 lbs. Indian meal, 6 lbs. Indian corn, 529 lbs. cake, and 363 lbs. oats. Their live weight at the commencement was respectively, 100 lbs., 108 lbs., 96 lbs., and 89 lbs. At the final end of the trial they weighed 188½ lbs., 181½ lbs., 183½ lbs., and 190 lbs. There was thus an average gain on each of 87½ lbs., or 350½ lbs., on the whole, equal in money value, calculated at the same rate per lb. as in the former cases, to £8 15s. 3d.—16s. 3d. less than Mr. Hardie's Leicesters, which consumed 40 lbs. less clover, 440 lbs. less turnips, 213 lbs. less mangels, 4 lbs. less hay, and 16 lbs. less hay chaff, but 53 square yards more grass. The trial, therefore, would seem to show that Lord Kinnaird's Leicesters are the most profitable keep, omitting the wool. A thorough test, in addition to the particulars above given, would include the price of fleece, the age, and the values of the sheep at starting. Taking the latter in a rough way; at 6d. per lb., we find that the original value of Colonel Inge's four was £8 13s., and the produce in twelve months, £7 7s. 9d.; of Lord Kinnaird's Leicesters, £8 0s. 6d., to yield £7 14s. 6d.; of Mr. Hardie's Leicesters, £9 3s., to produce £9 11s. 6d.; and of the gray-

faced Cotswolds, £9 16s. 6d., to return £8 15s. 3d. In proportion to their value, Mr. Hardie's and Lord Kinnaird's Leicesters again show best. Of course this reckoning is not free from empiricism; but we think it is sufficiently indicative of the value of each class of animal to be of some little use to those interested in sheep feeding.—*Scottish Farmer.*

### Farm Capital.

Money is needed by the farmer in the prosecution of his business—(1) for payment of rent and taxes for the land he hires; (2) for the purchase and maintenance of implements, of draught animals, and of steam power for the cultivation of the land, and for the conversion of its produce; (3) for the purchase of seed and manure; (4) for payment of labour during the year; (5) for the purchase of live stock by which to consume the green produce of the farm, and by which to provide the home supply of manure on which its fertility must depend.

It is plain that the amount which is made up of these items will vary exceedingly with the circumstances of the farm—(1.) Rent may not be asked for out of capital at all; the landlord may give twelve months' credit and ask for it directly (as he necessarily always does essentially) out of the produce of the land, not out of the capital which the tenant brings on it. Rent, moreover, whether long credit be given for it or not, varies between wide limits according to the quality of the land. It may be 15s. or 20s. an acre or it may be 40s., 50s., and it may vary even from 5s. to £5 per acre, according to the fertility of the land and its neighbourhood to good markets.

(2.) The amount needed for the purchase of farm implements and draught animals necessarily varies with the quality of work needing to be done. Stiff clay arable land cultivated highly needs more costly equipment in this way than lighter, poorer soils, more easily cultivated and laid down probably two years out of every five in grass; and both need larger outlay on implements and power than pasture land. The implements of arable land will cost from 15s. to 25s. an acre, and the horse power perhaps 15s. to 30s. an acre. This supposes steam-power to be *hired* for thrashing purposes. If it be provided for steam cultivation, a twelve-horse engine and apparatus, displacing twelve or fourteen horses and their implements and somewhat more, must be added to the capital thus required.

(3.) The amount needed for seed and manure is also extremely variable. From 10s. to 20s. for clover, and grain crops, and from 2s. 6d. to 10. for root crops; probably from 10s. to 15s. on the whole arable farm will be needed for the former; while for the latter the sum required varies from nothing up to as far as another rent, according to the spirit of the farmer and the proved experience of the locality. There are

many farmers who pay £1 per acre annually for artificial manure.

(4.) Labour varies from 4s. or 5s. an acre on grass up to 50s. per acre on our arable land. In the "Hand-book of Farm Labour," the particulars of farms amounting to 7,824 acres of acres of arable land, and 1,690 acres of pasture, are given; the wages paid on these farms were £14,423 per annum, or, deducting £423 for the pasture, 33s. an acre for the arable land.

(5.) The capital needed for the purchase of live stock and for extra food for them is the last item on the list, and this obviously will differ with the fertility of the land, the activity of its cultivator, and the rotation of crops adopted; and even in the case of pasture lands, where the natural fertility of the soil is the leading point, it varies from £2 or £3 an acre to £12 or £14—the grass in the former cases fit for little more than a sheep or two per acre, and the latter feeding annually a heavy bullock. On ploughed land the influence of various rotations comes into play, and the quantity of meat made annually per acre has been shown to vary from 30 lbs. or less up to 1 cwt. or more. In the former case it is plain that the stock will not need to be more than a sheep to every acre or to every  $1\frac{1}{2}$  acre; in the latter, it may be as much as three sheep or more per acre. But these calculations do not proceed upon the more economical processes now adopted, in which roots are pulped or steamed, and straw is cut into chaff, and much purchased food is used, so that the estimate of the capital under this head may vary from £1 or less per acre up to £5 or more, or when heavy crops of roots or straw are grown and double crops of vetches and rape, &c., are taken and consumed upon the ground.

Adding these items together, it will be found that the capital required on arable land varies from £7 to £15 per acre. Of these sums a varying portion will be payable on entering the farm on valuation to the out-going tenant, who will have spent for his successor certain amounts under most of these headings.

He may have paid for labour and for seed and for manure upon certain portions of the farm, and he may hand over by valuation certain portions of the implements and live stock which he has used upon the farm. Of the remainder a varying portion under most of these heads will not need to be paid until after harvest, when means may be provided for the purchase of live stock, and for the payment of rent by the sale of grain. In this way the burden of these demands upon the purse of the farmer is considerably reduced.

Nothing has been said of works for the permanent improvement of the land, which are properly a landlord's portion, but which, if the tenant be secured for long enough in his occupation may be profitably undertaken by the latter. Almost unlimited scope for the profitable application of capital to land is thus provided over a

great extent of the island; and the influence of the lease in leading thus to the higher cultivation of the land has been already referred to.

As a last word upon the capital of the farm, it may be well to remind the farmer of his interest in insuring his capital, however it may be invested, against the risks of fire, disease, and death, which will be accepted for him by the various insurance companies on payment of an annual premium.—*From 21st Edition of Arthur Young's Farm Calendar.*

## The Agriculture of Sweden.

TO THE EDITOR OF THE MARK-LANE EXPRESS.

SIR,—Having just concluded a two-months' fishing tour in the central provinces of Sweden, I extract from some memoranda, chiefly relating to matters piscatorial, a few notes on the farming of the country, which perhaps may not be entirely without interest to some of your readers.

The district I refer to, and which extends from Gothenburg and Uddevalla on the west coast to Northkopping and Stockholm on the east, consists of extensive tracts of table-land, rugged hills, chiefly of granite, but occasionally alternating with primitive limestone, vast pine forests, and lakes resembling in magnitude inland seas. There is soil here of every variety, from the stiff clays yielding heavy crops of wheat, beans, peas, clover, and timothy, to the sandy and peaty soils appropriated to the growth of rye, oats, barley, and potatoes.

The farms in Sweden, strictly so called, are not numerous, more than three-fourths of the kingdom being in the hands of peasant proprietors or freeholders, a kind of petty yeomanry holding from 5 to 100 acres of arable land, the average being about 30. This independent class of men generally becomes wealthy by the same process which enriches so many of our pastoral farmers in the dales of Yorkshire and Westmoreland—the keeping down of all outgoings on land, or living and laying by of all the incomings however small. Some, however, whilst retaining their peasant rank, live in comfortable style, keeping good steeds in the stable, and good wines in the cellar, and perhaps represent their class in the Royal Assembly, of which the House of Peasants is the largest if not the most influential branch.

In addition to his arable ground, the peasant has invariably a tract of rough pasture land, generally moor, mountain or forest glade, where he pastures his cattle in summer, cutting the best part of it for hay. The holder of 20 acres of arable will thus keep six or eight cows in addition to a pair of working bullocks and a horse, their sole subsistence in winter being straw and wretched hay; for the peasant rarely grows roots or clover, but cultivates his land, as his fathers have done before him, on the two-course

shift, half-fallow, half-grain alternately, about one-seventh of the fallow being dunged yearly; the great object apparently being to grow as much grain as possible with the least expenditure of labour and manure. Vast tracts of rich loamy clay on the east coast of Lake Wetteren have been so cultivated from time immemorial, and still yield weighty crops of grain.

The Swedish farmer is of an entirely distinct class from the peasant, and, in virtue of his usually superior education and creditable character and habits, occupies an important social position. He is generally the Thane of his district, a man of urbane address and liberal ideas, and does the honours of his house and table, which are seldom wanting in the elegancies and comforts of life, with graceful and genial hospitality. He is often obliged to be as much *merchant* as agriculturist; for a Swedish farm, in addition to its generally large extent of arable land, frequently includes a flour mill, a saw mill, and a roofing and draining-tile manufactory, and perhaps a Brunvin distillery, where the potato crop is converted into spirits.

The peculiar features of a Swedish farm may, perhaps, be best understood by a description of one in the occupation of a very enterprising agriculturist at whose house I had the honour of being most hospitably entertained. The farm of Graffnaas, near Allingsås, comprises 9,000 acres, of which 1,000 are arable, 500 pasture, and 7,500 forest. The rent is £800 a-year. The soil varies from stiff clay to light loam, but is chiefly loam on a clay bottom. The fields are large—from 40 to 80 acres; 400 acres are in oats, the land being at a high elevation; 40 in wheat, 80 in rye, a few acres in oats and vetches for horses, and 20 in turnips and potatoes. The land reserved for pasture is not sufficiently good for arable, being for the most part marshy, or cumbered with rocks or brush-wood. All the best of this pasture is mown yearly, without any return of manure, which is never applied to meadow land in Sweden.

The forest portion of the farm is chiefly valuable as affording small holdings for *torpare*, an inferior grade of peasants, who render to the occupier of the farm, in lieu of rent, labour in proportion to the value of their respective tenures. Thus the holder of from 20 to 30 acres works for the farmer, personally or by substitute, every day during June, July, August and September, and two days a week the rest of the year, *extra* labour being paid for at half the usual rates, namely, half a rix-dollar, or 7d a day for a man; one third of a rix-dollar for a woman, and one-fourth, or 3½d for a boy; this scale being reduced in winter. In summer the men work from five in the morning till eight at night, after which they have often some miles to walk home. It is not unusual to see farms advertised to be let or sold, as having the right of five, ten, or twelve thousand day's labour in the year attached to them. In the farm of Graff-

naas 2,000 acres of forest land are held by torpare or bonders; 300 in small out-lying patches of arable, the rest consisting of open glades, scrub, or marsh. The torpare on this farm, including all ages and sexes, amount to about nine hundred souls, of which about two hundred and fifty are available for work, and the average amount of labour done by them on the farm is that of forty men daily the year round. The horses of the torpare (in this case about forty) are also at the disposal of the farmer; but this right is sparingly exercised, except for the carting of timber for farm or household purposes, or of grain to market, or during harvest-time, when they are frequently all summoned to the field. The peasant has this protection against an oppressive exercise of authority, that he is at liberty to quit his holding after fifteen months' notice, which he must also receive before he can be discharged from it.

The management of the Graffnaas Farm would reflect credit on any Norfolk or East Lothian farmer. The fields, roads, ditches, &c., are beautifully kept; the under-drainage which now extends over one-half of the farm, has been scientifically conducted, the drains, 4 feet deep and 22 feet apart, being uniformly in the direction of the fall. On this point the Swedes appear to be generally in advance of many of our Yorkshire farmers, who still adhere to the diagonal direction, without considering that on this system only one side of the drain will act. Another point on which I believe most English farmers might take a lesson from them is that they invariably begin to lay the pipes at the upper instead of the lower end of the drain, thus avoiding what otherwise so often happens, especially in wet weather, and when the fall is slight, the sludging up of the pipes as the work proceeds. The pipes used at Graffnaas are 1½-inch, the main drain consisting of six, laid pyramidally.

The rotation on this farm is—first year, fallow dunged; second, rye or wheat; third, clover and timothy, one crop; fourth and fifth, ditto pastured; sixth, wheat, half-dunged; seventh, oats; eighth, peas, tares, potatoes or turnips, with bone-dust, or oats again without manure. 18 pairs of work horses are kept, and there are 160 head of dairy cows, and forty heifers and calves, which (contrary to the usual custom in Sweden of keeping the cows in the house till the hay crop is off) are pastured from the beginning of May till the end of September. Two-thirds of these cattle are of the native breed (worth about £6 a head), the rest either pure Ayrshire or crossed with Ayrshire, 20 cows and a bull of that breed having been entrusted by the Swedish Government to the farmer, with a view to the improvement of the breed of the district. The only return required by the Government for this gift is that of two bull calves yearly, which are sold on behalf of the State, or consigned gratuitously to other farmers. The consignee of these 0 cows is further restricted from selling their

male offspring till they are two years and a half old, prior to which period they are not supposed to have attained the requisite vigour or development. The improvement effected by this cross on the native breed—which are too frequently such as the patriarch Noah would, probably, have hesitated to admit in to the ark—is very marked; and my opinion was frequently and earnestly asked, as to whether any superior advantages would accrue from the use of a Short-horn bull in the place of an Ayrshire; a question which it is difficult to decide, considering the inferiority of the pasture and the severity of the winters generally combined to render necessary the house feeding of the cattle 7½ months in the year, and that the staple food of the people is not beef and mutton (of which they produce and import but little), but rather bread, milk, cheese, and butter, the imports of which actually exceed in value (in this extensive and thinly populated country) £400,000 yearly. The question was more than once asked me, “Why do not Englishmen, possessed of a little capital, come here instead of going out to Canada or Australia?” and it is perhaps worthy of consideration, whether a country so near our own shores, and in many respects so favored might not afford scope for the energies and enterprise of British Agriculturists who feel the want of elbow room at home. My own impression, however, is, that were a man of moderate capital to emigrate there, with the idea of teaching the Swedes, and to introduce costly implements or expensive cattle, or any material innovations upon the established system of farming, without due regard to the exigencies of the climate and country, he would soon find himself at the end of his tether. For example, high-bred cattle would scarcely be remunerative in a country where beef and mutton, generally indifferent enough in quality, but excellent under the Swedish mode of cooking, may be bought for 3d. and 4d. per lb., and capital veal for 5d. Reaping machines would hardly effect a saving, where stout men can be had for the work at the rate of a penny per hour; or threshing machines, where threshers are contented to take every fifteenth or sixteenth sack in lieu of money wages. Two steam-ploughs have been introduced into Sweden by a wealthy landowner—one into the South, the other to a farm 20 miles from Wettersborg; but it is credibly reported that the labour of men and horses employed in the transport alone of English coal, by necessarily light loads over the hilly country, would suffice to plough the whole farm.

It is more than doubtful, therefore, whether any English settler, imbued with English notions of scientific cultivation, would meet with much success in a country where the conditions of climate and labour are so different from his own; but were he first to acquire by a year or two's tutelage under some intelligent farmer, a knowledge of the language of the country, and of the system of agriculture, which the observation

and experience of practical men have established there, and after maturely considering the nature and requirements of the soil and climate, cautiously and gradually to improve upon, rather than alter existing practices, judiciously applying the cheap labour at his command, and making the most of the internal resources of the farm, so as to avoid all unnecessary outlay on experimental farming, implements and manures, he would then, probably, receive better interest on his outlay than appears to satisfy so many of our agricultural farmers at home, in these days of high rents and heavy taxes. Were he further to possess the requisite mechanical skill and mercantile knowledge, he might probably turn the mills and factories, so frequently appertaining to Swedish farms, to very profitable account. Thus, on one farm north of Uddevalla, were two flour mills, with eight pairs of stones, working night and day, the year round, and yielding a clear annual profit of above £400 a-year. The manure left by the horses bringing grist to the mill, and waiting there, exceeds 1000 cart-loads yearly. There was here also a tape manufactory employing 40 hands; a small iron-foundry where castings were made, and nails, ship-anchors, hawsers, and wheel tires forged—the ponderous hammers, the furnace blast (of three cylinders), and whole machinery being worked by the never-failing water-power of a magnificent trout and salmon stream. The farm here had evidently suffered from the attention of the tenant being divided between it and the more important occupation of his mills. It was neglected and unproductive, though I observed upon it a source of fertility invaluable in a granite district—extensive beds of calcareous matter in the form of marine shells, in an apparently calcined state, sometimes imbedded in blue clay, and retaining their perfect shape; and sometimes, where almost unmixed with earths and crumbled by exposure to the air, closely resembling bone-dust.

In one respect, and under not unusual circumstances, a Swedish farm would seem to hold out to a man of small capital, advantages which are not offered in this country. I mean that of taking the farm with the live stock, horses, and implements upon it, thus enabling the tenant to retain his farming capital to meet rent and expenses till his grain crops become available for that purpose. Thus, a Swedish friend of mine lately had the offer of a farm at Linköping, the capital of the rich province of that name, lying on the east of Lake Wättern, consisting of 520 Scotch acres in 10 fields of 50 acres each, 20 acres being in meadow. The soil is principally loam and marl on clay sub-soil, about 50 only being hard to work, and that not so stiff as much of the land in the Carse of Gowrie. The stock, which is let with the farm, consists of 60 cows, 19 pairs of working oxen, 5 pairs of horses, some young colts, 50 sheep, and excellent and extensive buildings and dwelling house, the latter with 13 rooms. The rent asked was £525

English, and if from this be deducted £50 a-year as the produce of a saw mill and flour mill, and £50 on the score of cattle and implements (which may be estimated as worth £1,000), it leaves the rent about 16s. a long acre. £60 a-year covers all government, parochial, and other outgoings, and there are six torpare or free-labourers.

The yield of grain in Sweden varies, according to the season, soil, and husbandry, from four to six quarters of wheat to the long acre, and from four to eight of barley. The price of wheat is from 45s. to 60s. the qr., according to quality and the markets; barley, 25s. to 30s.; rye, 32s. to 35s.; oats, 16s. to 20s. This year the yield and quality of the grain, owing perhaps to the moist spring and cloudless summer and autumn, is without precedent. The farmers know not where to bestow their increase, and it is calculated that at least three millions of barrels will be available for exportation.

In speaking, however, of this year's yield of grain in Sweden as unprecedented, it must be remembered that a greatly extended area of land was brought under cultivation in the time of the Russian war, when rye rose from 13s. to 30s. per barrel, and land temporarily at least, about 50 per cent., and that, under the impetus then given to agriculture, deep drainage and tillage, with careful cultivation, have yearly made rapid progress, and resulted in increasing produce; the very peasantry beginning to feel that agriculture is a progressive art, and exhibiting, in many instances, a spirit of active improvement. The marvellous increase of produce in Sweden, wherever thorough-drainage has been effected, leads irresistibly to the conclusion, that the vast tracts of stiff retentive soils yet undrained, or drained only by open trenches and water furrows (the inefficiency of which appears in stunted crops and coarse herbage), would afford profitable employment for English capital. Sweden is peculiarly a poor country, and there are everywhere (but especially now, under the depression caused by the American war,) estates on sale. Not more than one-third or one-fourth of the purchase money is usually required to be paid down, the payment of the rest being extended over a series of years. It is impossible, of course, to give any very accurate idea of the value of estates in that country; but, at a loose computation, it may be said that five hundred acres of average land may be purchased for £10,000, the addition of two or three thousand acres of pine forest not materially enhancing the price, unless where the vicinity of a navigable river gives a marketable value to the timber. Such purchases should, of course, be judiciously made; if possible, near some line, or projected line, of railway, canal or navigable river, or seaport—the land sufficiently concentrated, and as level as consistent with easy drain-age, and the buildings—as is almost always the case in Sweden—con-

veniently placed, extensive, and well-arranged. Such farms, I think, let to intelligent tenants—the landlord providing for them draining pipes, and subsequently lime, and exacting under occasional supervision, a proper system of drainage and cultivation, but at the same time an easy rent at the outset, augmentable to a certain extent in a specified ratio yearly, as the condition of the farm and its tenant improved—could hardly fail to return a much higher rate of interest than is compatible with anything like good security in England; to say nothing of the prospect of more or less increase to the saleable value of the land, as the resources and riches of the country are opened up and increased by the construction of railways. Thus, land in the neighbourhood of Gottenburg has increased cent. per cent. in the last ten years; and in the event of the expected union of Denmark with Sweden and Norway, when Gottenburg from its central position and advantageous sea-board, would probably become the seat of government and the converging point of numerous railways, must continue to advance in value.

The climate of central Sweden is delightful, the atmosphere being, in the opinion of old Australians, more clear, buoyant, and invigorating than that of their own settlement; and the scenery, without attaining to the wild grandeur of Switzerland or even our own Lake districts, is generally picturesque. The winters, though severer, are drier than ours; the weather in summer steadier and warmer; wet hay-times and harvests are of rare occurrence: and vegetation is so rapid that corn is sometimes sown and reaped in six or seven weeks. Nowhere on the face of the earth will an Englishman meet with more hospitable welcome and hearty kindness than in Sweden and Norway. I say an Englishman; for between the people of Britain and of Scandinavia there seems to be a mutual sympathy and bond of alliance, arising probably from the affinity, and, in great measure, common origin, of race, manners, customs, and institutions. In Scandinavia, alone, perhaps of all the nations of Europe, is England regarded with feelings where envy and dislike have no place; and to that quarter alone must her statesmen look, should ever be deemed desirable to for a powerful and enduring Northern League.

I have spoken of the steadiness and warmth of the climate in Sweden; yet with these advantages they adopt measures for the speedy drying of the crops, which might be copied with benefit in the rainy districts of these islands, especially where access can be had to the thinning of fir plantations. The most simple mode of drying grain is by rearing a number of light poles, about 9 feet high, in holes made for their reception by an iron crowbar. A pair of sheaves are placed upright against the pole to support the other sheaves, which are then linked two and two together and threaded upon the pole at the junction of the bands, so as to rest in a hori-

zontal position one on each side of the poll. The rest are similarly placed till the top is reached, where one sheaf is then impaled through its centre. In the districts bordering on the Baltic extensive frame-works are used. A number of fir poles, about 20 feet high and 4 yards apart, are erected in a row, usually running north and south. At each side of these poles, namely, east and west of them, and 2 feet apart from them, is erected a lighter pole, 1 foot shorter. Across each of these three poles are then nailed or pegged nine cross-bars, 2 feet apart, and two sloping pieces are placed at the top to support a roof, falling two or three feet each way. From each of these nine cross-bars to the opposite cross-bar are then laid four loose poles, generally of split fur, thus making between each pair of uprights a series of nine shelves, 4 yards long and  $4\frac{1}{2}$  feet wide, on which the fresh cut vetches, clover, or timothy, or in wet seasons, grain, are placed and closely packed, and there remain till dry, proof against any damage from rains. It is of course necessary to prop against every other upright a sloping poll as a buttress: and this on both sides, unless when two parallel ranges are constructed a few yards apart, in which case it is sufficient to spur them on the outside, steadying them on the inside by a few poles stretched from roof to roof, and fixed at the ends as tie-rods.

A simpler and less expensive plan is in use in the western districts. Several couples of fir poles, about 8 yards long, are raised, at intervals of three or four yards, against each other, after the manner of a steep house-roof; the upper ends, which are pegged, cross or overlap each other sufficiently to afford a rest for the horizontal ridge-pole, which combines the couples. On the outside of these couples are inserted, at right angles to the slope of the pole, and 2 feet apart, wooden pins, about 8 inches long, to afford support for a series of loose horizontal bars, which are then laid from one to the other, thus completing the frame or rack. The laying on of the crop (which, whether of grass, clover, or grain, and however laid and twisted, is all cut with a short light scythe, which the mower wields in an upright position, cutting close to his feet) is then commenced by hanging the swathe over the lowest bar (which is two feet from the ground), till it reaches the next bar. The workman then stands upon the first layer whilst he fills the space between the next two bars, and so on till the ridge is reached, where a little straw or thatch is usually laid to turn the water. When grain is dried in this way the heads are put through the bars, the butt-ends being outside and inclining downwards; the whole resembling a thatched roof.

I fear that I have already trespassed too far upon your space, and remain, sir, your obedient servant,

WM. CARR.

Stackhouse, 18th Sept. 1862.

### Town Sewage.

A good deal of light is thrown on the subject of town sewage, so far as the possibility of turning it to agricultural account is concerned, by the ordinary experience of the farmer.

1. It is the experience of the farmer that manure is just food *minus* growth, and that it is rich or poor according to nutritiveness of the food and the meagreness of the growth. He knows that the manure from store-fed growing stock is less fertilising and powerful than that from well-fed fattening-beasts. Now, man is one of the best fed of the "domestic animals," and inference seems unavoidable.

2. Although it is certainly true that we have nothing in ordinary agriculture corresponding to the immense quantities of fertilising matter which are thus poured over the sewage meadows of Edinburgh and Carlisle—nothing corresponding to the 300 animals in one case, 200 animals in the other, averaging probably 20 or 25 lbs. a quarter, whose waste is in these two instances applied per acre; yet it is undoubtedly the experience of the farmer that an increasing intensity of manuring *is* the rule, and is found profitable. Of that our columns have for several past weeks given ample evidence.

Mr. Hudson, of Castleacre, on his 800 acres of arable land, must use 40 tons of guano, 4 tons of nitrate of soda, and 25 tons of superphosphate and lime per annum, costing close on 20s. an acre over the whole of his farm. And besides this he consumes immense quantities of purchased cattle food, which goes to enrich the farm-yard dung. Mr. Howard, of Biddenham, Bedford, consumes £1,000 worth of cake and other cattle foods per annum, and thus enriches the manure of the stock on a farm of 300 acres of arable land and 120 acres of pasture. Mr. Paget, M.P., of Ruddington Grange, Nottingham, consumes 30 tons of cake and 200 quarters of corn, costing probably upwards of £500 or even £600, on 150 acres of arable land and 180 acres of pasture. Mr. Melvin, of Bonnington, Ratho, on a farm of 600 to 700 acres, spends £1,000 on artificial and purchased manures. Mr. Campbell, of Buscott Park, Lechlade, has found it profitable, after drainage, to apply  $1\frac{1}{2}$  cwt. of Peruvian guano, 3 cwt. of superphosphate of lime, 1 cwt. of nitrate of soda, 15 bushels of bone-dust, and 1 cwt. of common salt per acre over his permanent pastures, and thereafter to feed sheep, five to eight of the large Lincoln sheep per acre, giving them cake in addition daily on the grass. This treatment has been adopted with great success over more than 1,000 acres of permanent grass. On an East Lothian farm of about 300 acres of arable land known to us, 18 tons of Peruvian guano, 12 tons of

bones and superphosphate, 6 tons of nitrate of soda, 3 tons of rape dust, and 3 tons of common salt are used, costing close on £400 per annum. On a farm of 280 acres of arable and 400 acres of pasture near Tavistock, Mr. Horswell applies 3 to 5 cwt. of Peruvian guano per acre to about 50 acres of swedes and mangels, consuming also with feeding cattle about 60 acres of barley and oats, about 25 tons of oil-cake, and 20 tons of bran per annum. The expenditure here must be £700 in cattle food, and £150 in artificial manures, on 280 acres of plough land.

These, then are ample illustrations of the fact that enormous quantities of fertilising matters are now commonly applied in English agriculture to the soil—that the soil is indeed being considered as a machine through which we put as much of the raw material of farm produce as by means of certain crops it will profitably convert, and that, therefore, there is nothing in ordinary agriculture to forbid the possibility of even the extraordinary supplies of fertilising matter which town sewers now for the most part send to waste being profitably used on a comparatively small extent of land.

3. It is the farmer's experience, moreover, that manure is more effective in the liquid than the solid form. If any one wants proof of that let him read Mr. Rustan's capital paper on the water drill in the 20th volume of the English Agricultural Society's Journal. Four to ten tons per acre of mangel wurzel, 30 to 40 per cent. of coleseed, a greatly increased produce of oats per acre, is obtained by the simple expedient of "flushing" in the manure that is applied at seed time with 3 or 4 hundred gallons of water to the acre. Another illustration of the advantage of putting manure in with water is seen in the superior efficiency which artificial manures exhibit in Scotland and the wetter climates of the island generally, as compared with their effect in the south-eastern drier countries. A third illustration of the same truth is found in the experience of the manure manufacturer and merchant, that a dry season is fatal to his trade. As a general rule, farmers do not buy these things until they are prepared to use them. And they know that it is useless to apply them in a dry state of the land and of the weather. The consequence is, we are informed, that nobody in the country uses the electric telegraph more than the agriculturist or his agent the local manure dealer, on any change of weather, as from a drought to rain, at this time of the year. The Thameside manufacturer is thus urged to the utmost, and superphosphates are sent off at the rate of hundreds of tons a day during the first wet week in April, May, or June, after a period of drought. It is undoubtedly also true that an

extremely wet season is also injurious to the manure trade, but that is owing, not to such weather being injurious to the action of the manure (the contrary is the case), but to its hindrance of the work of preparation of land for the crops to which such manures are applied during this and the following month.

4. It is, however, the farmer's experience as a general rule that liquid manure is "more plague than profit." That this arises, perhaps, as much from his keen sense of its being a plague as from any well ascertained experience of its not being profitable may be admitted; for undoubtedly the use of the water cart enforced by the tanks being full at times when it is inconvenient to take the horses from other work—enforced too, at times when it is often unadvisable to apply manure to all; and, indeed, the use of the water cart at all—a new machine and new process altogether, hitherto unknown to ordinary agricultural routine—is felt to be a plague. Nevertheless, the profitableness of the process, considering the extremely diluted nature of the manure, and the labour of its conveyance in this way, is often doubtful. The fact is, water should be the carrier of the manure, not merely the thing carried. And the prejudice (shall we call it) which leads the farmer to condemn the practice of carrying it to the land directly as manure, as a regular part of farm management all through the year, will yield when the labour of it disappears, and its fertilizing influences are obtained under the system by which a dilute liquid manure is its own carrier in large quantities to the land over which it is proposed to take it.

5. But then it is the farmer's experience that tillage operations are necessary during the growth of many of our crops; that a dry, or comparatively dry, condition of the land is necessary during the ripening of seed; that land cannot be tilled and seed cannot be ripened except the soil be comparatively dry. This, then, shuts out from the possibility of benefitting by these large liquid applications of manure a very large number of crops. Whether grain crops will benefit by such dressings during the grassy stage of their growth has yet to be satisfactorily proved. At any rate, land cultivated for grain crops cannot be that constant scene of sewage operations throughout the year which land must be to take the constant supply of sewage yielded by towns throughout the year. And, indeed, this truth almost entirely shuts us up to the use of the grasses as the only plants to be cultivated under the influence of liquid and sewage manures applied in large quantities. There are among the grasses particular species which are endowed with extraordinary powers of growth, and consequently of absorbing food. What we want is a plant which shall have in

its natural constitution, as exhibited in our climate, a power of growth corresponding to the quantity of food which in sewage manure is applied to the land.

A good deal of evidence has been taken before the committee of the House of Commons on this subject, as to the power of soils to store away the fertilising ingredients of manure for future use. And so far as regards its application during the winter season, when the weather checks the growth of grass, a conserving power of the kind is, no doubt, useful.

But during the summer, the time of growth, what we want is not a soil to lay up these fertilising matters as supplies against a time of use. The summer is the time of use. And what we want is a plant which shall be capable of using the material as it arrives. For this reason, too, the manure as it reaches the plant must be capable of giving out its fertilising matter for its use at once.

That of it which is capable of feeding the plant must be in a condition prompting it to leave the water holding it in solution on the very slightest invitation, and indeed to leave it without any invitation at all. For we believe that the maximum produce of grass is obtained when the air immediately above the flowing water is capable of feeding the leaves beneath which it flows, at the same time that the water is feeding the roots. In Italian ray-grass we have a plant exactly of the kind required, so also in many other grasses; for the Craiginny meadows, which yield such extraordinary produce of grass, contain little, if any, of the Italian ray-grass. It is in these grasses, then, and not in the soil, that we are to find the true machine for extracting the food which sewage yields. The mischief which it does and the nuisance which it is must be reduced to a minimum by turning it to use in this way in districts where the population is at a minimum.

The facts and arguments thus addressed to the reader must lead him, we think, to the conclusion that the sewage of great towns like London should be taken many miles away to where sandy slopes exist, over which it may be poured, and through which it will filtrate easily, and by means of which, or rather of the grasses which may thus be grown upon them, or rather of the cows which may be fed upon the grasses, the filthy stream may "by cleanly manipulation" be converted into milk.—*Gardeners' Chronicle*.

### The Value of Food.

Abundant, nay superfluous evidence has been furnished to prove that no one principle of food will alone suffice for nutrition; but clear and unequivocal evidence is still wanting to show how far each principle of food is essential to life

and health, provided all else save that one be sufficiently supplied. This is a very different question. Again, ever since Liebig's classification of food into plastic or nutritive and respiratory or calorific, some most important questions in connection with it have engaged the attention of physiologists. Amongst them are these:—Is any food destined to the production of heat without being concerned in the repair of tissues—that is, is any portion of the food directly burnt in the blood? Is any portion of albuminous food directly calorific, that is, burnt in the blood without forming tissue?—Experiments were performed upon rats and a hawk. The animals were fed upon different diets, and the experiments may be divided into three classes accordingly. In one class the diet was a non-nitrogenous one, consisting of equal parts by weight of arrowroot, sago, tapioca, lard and suet; for this mixture was found upon analysis to yield only 22 per cent. of nitrogen. In another class the diet was a nitrogenous one. It consisted of lean veal from which every visible particle of fat had been carefully removed. This yielded upon analysis only 1.55 per cent. of fat. In the third class the diet was a mixed one. It consisted of a combination of the two former diets. From these experiments the following conclusions are drawn:—Nitrogenous materials are not only calorific, but, at least under some circumstances, sufficiently so to maintain alone the requisite temperature. It is in the highest degree probable that, under certain circumstances, nitrogenous materials may prove directly calorific without forming tissue. Non-nitrogenous substances are at least under some circumstances, directly calorific without entering into the composition of tissue of any kind. While non-nitrogenous food only is taken, all the nitrogen which is excreted in the urine, and more, may be accounted for by the disintegration of the original tissues, without assuming that any fraction is assimilated from any other source. While life cannot be maintained without nitrogenous food, even though every other kind be abundantly supplied, death in this case being due to loss of tissue, life and even health and the normal temperature can be maintained, at least for a long period, upon a diet almost exclusively nitrogenous, with proper inorganic substances in which there exist only a small fraction of non-nitrogenous matter. Such a minute proportion of fat must be but a poor representative of non-nitrogenous food. Moreover in these experiments some of the rats sustained a loss of weight considerably above 50 per cent. When their temperature is maintained from external sources, or when they are freely supplied with calorific food, warm blooded animals may die rather from waste than loss of temperature, as perhaps is the case with cold blooded animals when they are starved. Lastly, in these experiments the significant fact appeared, that while the

weight, strength and general condition of the animals varied very widely under the different diets to which they are subjected, no considerable fluctuation was observed in their temperature. Even the slight variation from time to time recorded seemed rather to result from other causes than to depend directly on the food.—*W.S. Savory, in Proceedings of Royal Society.*

### South Australian Farming.

Among the several flourishing colonies of of Australasia, that of South Australia seems to take the precedence i. a purely Agricultural point of view. It not only sustains immense herds and flocks, but has been very successful in the cultivation of the cereals and root crops. Some of the finest wheat in the world has been produced in this, and the adjacent colony of Victoria. We are happy to hear of the prosperity of our fellow colonists in that distant part of the Empire, and our readers will be interested in the following article from the last numbers of the *Mark Lane Express*;

The last overland mail has brought us some interesting details from South Australia, which seem to mark the growing progress of this important and rising colony. The high position which it has recently taken by the awards conferred by the Jurors at the International Exhibition has led to a demand for information on the part of the public respecting its resources and present condition. The statistical details just taken in the colony furnish most *apropos* all that is required with regard to its land, crops and live stock.

From these official returns it appears that at the close of 1861 the total quantity of land alienated from the Crown, in South Australia, amounted to 2,379,048 acres, of which 1,393,672 acres were in the occupation of the proprietors themselves. As respects average price per acre, with the exception of 1861 which shows a little advance in price as well as in quantity sold, the sum realized has been gradually falling away for several years. Of late the acquirement of land has outstripped the increase of population, until at the end of 1861 the lands alienated from the Crown in this colony amounted to 18.2 acres for every man, woman, and child in the province. The lands alienated in Victoria amount to but five acres per head of the population; so that the people of South Australia own, in proportion to their numbers, nearly four times as much land as the people of Victoria. The average extent of holdings throughout the colony of Victoria in 1859 was 218 acres,

and the average number of acres cultivated by each holder is 26. We have, as yet no means of comparing these figures with those of South Australia.

We have before us a volume of Victorian statistics from 1835 to 1860. At the last mentioned date the "holdings" were subdivided into nine classes, viz, under five acres; 5 and under 15; 15 and under 30; 30 and under 50; 50 and under 100; 100 and under 200; 200 and under 300; 300 and under 500 acres; and 500 acres and upwards. Of the first class there were 786 holdings; of the second class, 1,674, of the third class, 1,241; of the fourth class, 1,206; of the fifth class, 2,199; of the sixth class, 2,087; of the seventh class, 1,140; of the eighth class, 283; and of the ninth class, 967. It will hence be seen that the largest number of farms in Victoria are those that range from 100 acres to 200 acres each, and the next largest those that range from 50 acres each, and the next largest those that range from 50 acres to 100. The holdings of 500 acres and upwards include all the purchased lands, and represent a wider aggregate acreage than all the other eight classes combined. The total number of all the "holdings" in Victoria was 11,573—(exclusive of town and village allotments): the total acreage of those holdings being 2,519,156; and the total of increase upon the foregoing figures. On the 31st March, 1851, there were, in Victoria, 2,076,014 acres of enclosed land not cultivated, against 1,388,160 acres in South Australia, enclosed but not cultivated on the 31st March, 1862. On the same dates the land under tillage in Victoria amounted to 419,380 acres, and as the people in South Australia exceed the people of Victoria as landowners in the proportion of four to one, they surpass them as cultivators of the soil in the proportion of more than five to one. The Victorians, with their recent Land Bill and their permanent provision for immigration, are, however, trying new and important experiments, and we may expect to find the present great relative disparity between the agrarian interests of the two colonies gradually decrease.

The land fenced in, but not cultivated in South Australia, amounted to 1,388,160 acres, and exceeded the enclosed pasturage of the previous year by 236,984 acres. The number of acres under cultivation in the season 1861-62 was 486,667, against 418,816 acres in the previous season, an augmentation of 57,851 acres, or 31.5 per cent. These figures give 3.71 acres to each individual of the population; at the end of 1856 the rate per head was only 2.38 acres. Tillage increases at a greater rate than the alienation of the Crown Lands, 20 per cent of the land sold being under cultivation, against 19 per cent. in 1861, and 13 per cent. in 1856. Of the total land cultivated 310,636 acres or 64 per cent. was under wheat. The yield a-

mounted to only 3,410,756 bush. against 3,576,593 bush. in the previous season. This shows a deficiency of 2 bush. 5lbs. per acre, or over 400,000 bushels, had the yield been equal to the average of the year previous, although 36,994 acres additional were sown with wheat. The average yield throughout the province was but 10 bush. 59lbs., against 13 bush. 14lbs. in the previous year. This decreased production arose from gales and heavy rains in December, which shook out much of the grain, and laid the straw.

Another cause of the low average of the aggregate yield is, that much land was sown with wheat which was not of the description best suited for the successful cultivation in ordinary seasons of that cereal, a state of things doubtless owing to numerous small freeholders and tenant farmers being compelled, whatever the situation or the nature of the soil, to cultivate the crop, raised with the labour, and capable of being gathered by machine. More than two-thirds of the crops are reaped by machine in the colony.

Proceeding from the subject of the culture of wheat, which is at present almost the sole reliance of South Australian farmers, forming as it does two thirds of the whole cultivation, the next important crop to be noticed is that of hay, forming 13 per cent. of the tillage. 62,874 acres, principally wheaten or oaten hay, were grown, against 55,818 acres in the previous season—an addition of one-tenth, the produce amounting to 78,886 tons and 71,241 tons in the respective years. The average yield of the hay crop was the same in both seasons, or twenty-five hundredweight to the acre.

About one-tenth more land was planted with potatoes than in the previous year, 2,612 acres producing 7,726 tons in 1861-2, against 2,348 acres yielding 7,112 tons, the average produce being 59 cwt., or a hundredweight and a-half less than in the previous year. The above supply was insufficient for the local consumption; 2,450 tons, or nearly one-third more, having been imported at a cost of £13,419 for an article that could have been produced in the colony of equal quality to that imported.

The live stock returns show an addition to the number of all kinds of stock except horned cattle. There is an increase of 3,198 horses, making a total of 52,597; of which 47,434 are returned in the counties, and 5,163 in the pastoral districts. The shipment of South Australian horses to India and other ports during the past three years has obtained some importance, about 509 being the average number exported in each year. The decrease in the number of horned cattle is 12,831, a large falling off appearing in the number depasturing in counties; of which, however, there is difficulty in arriving at a correct enumeration. The total number in the colony is stated to be 265,533 head. Sheep

and lambs number 3,038,356 against 2,824,811 in the previous year, showing an increase of 213,545, or but eight per cent. in the year. The increase occurs chiefly in the more distant counties and in the other pastoral districts. The number of pigs has increased by 9,539, there now being 69,286 in the colony; notwithstanding, the imports of bacon, hams, &c., amounted during the past year to over seven thousand pounds value. Poultry of all kinds number 327,709. During the past four years the export of eggs alone has brought to the colony no less a sum than twenty-one thousand pounds.

Vine culture has attained such considerable importance in South Australia as to demand particular attention to the statistical facts elicited as to its position at the present time. The quantity of land planted with vines has increased rapidly. At the close of 1850 there were 282 acres; in 1854 409; 1856, 753; 1857, 1,055; 1858, 1,626; 1859, 2,201; 1860, 3,180; 1861, 3,918 acres. The number of vines was—in 1860, in bearing, 1,874,751; not in bearing, 1,948,510; total, 3,823,261. In 1861—in bearing, 2,361,574; not in bearing, 2,386,141; total, 4,747,715. The quantity of wine manufactured was in 1859, 182,087, and in 1860, 312,021 gallons. In comparing the quantity of wine made with the number of vines in bearing, it will be seen that only one gallon of wine has been obtained for each six vines. When the whole of the vines now planted will be in full bearing it is reasonable to expect that after deducting for the fruit, both fresh and dried, each vine will furnish a quart of wine, or a total of 1,186,404 gallons, being equal to 11,864 pipes of 100 gallons. Since 1856 the area of the vineyards has increased more than five-fold; and as during the last three seasons the number of vines planted has nearly doubled, those in bearing can form but a moiety, being the proportion shown above. The wine returned as made, is that produced in the season 1860-1, amounting to 312,021 gallons, an increase of no less than 129,934 gallons, or 70 per cent. on the quantity made in the previous year, viz., 182,087 gallons, and more than three times the quantity produced four seasons ago.

The weight of grapes sold or otherwise disposed of by the grower than in the manufacture of wine, was 23,229 cwt., against 23,398 cwt. in 1860-1; but it is probable that a large proportion of the grapes so returned eventually reach the winemaker, the purchase of small proprietors' crops by neighbouring vine-growers possessed of better appliances for the manufacture of wine, being now carried on to some extent, to the manifest improvement in the quality of this article of colonial produce.

At Chicago, on October 30th, 7 grain-loaded vessels cleared for Buffalo, 3 for Port Colborne, and 8 for Oswego.

## Agriculture of Colorado Territory.

The rich alluvial bottom lands of the Arkansas river are covered with a luxuriant vegetation, and wherever ranches have been commenced and farming labour expended, the results have been of the most satisfactory and profitable character. We were agreeably surprised to find such extensive improvements along the valley of the Arkansas.

The great objection heretofore urged against general agriculture in this region, has been the want of timely rains. This deficiency is now supplied by an extensive system of irrigation, and farmers find it even better dependence than rain, because they are able to moisten the earth at just the proper time, and to just such an extent as necessity requires. We have never seen finer corn anywhere than that grown this season on the Arkansas and Fontaine qui Bouille, and wheat, oats and barley have grown luxuriantly. All the other vegetable products have flourished bountifully, and the crops have in some instances yielded immense returns to their fortunate proprietors. We saw quite a number of wheat-stacks, which, on examination, proved to be equal to the best white winter wheat. The berry was plump and large, and the straw unusually fine. The yield per acre in some instances reached as high as forty-five bushels.

Ranchmen with whom I conversed, expressed their complete satisfaction with the fertility of the lands upon which they were laboring, and their entire confidence in the surety of a good crop, no matter how dry the season. Garden vegetables, melons, &c., are particularly prolific in yielding, and enormously large. At Fontaine City, at the south of Fontaine qui Bouille, we stopped an hour at the hospitable ranch of Mr. Leonard Johnston, and were regaled with the largest and most delicious watermelons and muskmelons we have ever eaten. Some of the former weighed fifty pounds. Other specimens of garden growth were exhibited to us, which would vie in size, quality, and abundance of yield, with the best ever produced in that celebrated region—Southern California.

As a grazing region, the rich bottoms and ranges along the Arkansas and Fontaine qui Bouille will compare favourably with any other portion of our territory. Stock raising is attracting the attention generally of the settlers, and already formidable herds of cattle and a few flocks of sheep are fattening on the hills. Another year and the farmers of this region will be enabled to supply in almost unlimited quantities all the vegetables and cereals for consumption in the southern portion of this territory. Fences are being built, ditches constructed, good comfortable buildings erected, and everywhere there is an air of enterprise

and thrift which characterizes all new and promising farming sections. Drouth is something which inspires no dread in the minds of the farmers of the valleys through which we rode. The facilities for irrigation are most admirable. Ditches stretching for miles in length, and carrying immense volumes of water, skirt the hillsides along the bottom, from which the grateful element can be diffused over thousands of arable acres at will. Timber, if not of the most superior quality, is abundant for fuel, fencing and building.

We do not wish in our remarks on this section, to be understood as disparaging any other agricultural portion of Colorado. All along the valley of the Platte, the Cache la Poudre, Boulder, Thompson, Clear Creek, and a few other streams, extensive agricultural improvements have been made, and, we presume, with equally flattering results. But we have made special mention of our southern farming interests, because we have fortunately passed through that promising region at the time when the bountiful harvest was just gathered, and when we could see and appreciate the productions and adaptiveness of our bottom lands for agricultural purposes. We are fully convinced that after another year passes, no more flour, corn, bacon, or animal food of any kind, will be freighted across the Plains to this territory.—*Exchange.*

### Weedy Neighbours.

There are few evils afflicting agriculturists that can compare with the mischief occasioned in a well-farmed district by the presence of a neighbour who *does not cut down his weeds*. At the present season, in some parts of the country, the air is actually filled with floating thistle-down; and, keep land as you may, if one has a *dirty neighbour*, high farming, in its true sense, is labour in vain. We cannot even hold proprietors guiltless in this matter of disseminating weeds; for from their woods and commons and warrens millions of seeds are hourly winging their flight to the garden-like farms of their tenants. In our columns mention was lately made of the institution of a Chamber of Agriculture. Here, then, is a fertile subject for immediate consideration, and one about which the Chamber could with good grace go to the Legislature for protection. In the colonies, our sharper brethren have long ago dealt with the question in a business-like way; and particularly in the colony of Victoria, a very heavy penalty is enforced from any one who allows weeds to go to seed.

Perhaps it may be thought by some to be inconsistent with British ideas of liberty and private rights, to interfere in such a case; but we cannot perceive the slightest injustice in

putting down such a nuisance; and a nuisance, in every sense of the word, it is. It would be invidious to mention individual cases; but we presume there is scarcely one of our readers who possesses a clear-kept farm, who could not at once point to some promoters of this evil, so rife at this particular season, and who does not fully sympathize with his brother-farmer who lives alongside of a "weedy neighbour." Commons in general, or seaside links, are often the great hotbeds and nurseries of this pest of thistles; and we have heard it mentioned that one in East Lothian supplies thistles for nearly the whole country. In the absence of the proposed Chamber of Agriculture, perhaps the committees of some of our agricultural clubs will put down for discussion during the ensuing winter the subject of "Weedy Neighbours;" and we shall live in hopes of seeing a short bill passing the House of Commons, compelling every one to cut down his thistles before they go to seed, and wing their flight to the farms of those who are compelled most unwillingly to receive them.—*Scottish Farmer.*

### Use of Leaves.

In many sections of our country, oak leaves are extensively used as bedding for domestic animals. They are gathered in the forests in autumn, and stored in some convenient place till wanted. This affords them time to dry, which increases their power of absorption, and renders them more valuable in taking up and preserving the liquid voidings, and also facilitates, through this means, the decomposition of the vegetable fibre when used as a manure. That oak or other kinds of leaves, operate powerfully when spread broadcast on the surface of mowing land, is unquestionable; yet this results not so much from the "astringent" matter they contain, as from the non-conducting power. We spread leaves around the trunks of trees, the blossoming of which it is desirable to retard in spring, we apply them also in "mulching," the object of which is to retain the moisture in the soil for the benefit of trees newly transplanted.

When they are spread upon the surface of grass lands, they present, to a very great extent, the action of the solar rays, and thus in a measure deprive the roots of the energizing and vitalizing influences upon which their strength and vigour very essentially depend. Whatever may be the effects produced by leaves, in their crude state upon cultivated vegetation, we see that they are eminently useful in woodlands, where, if they are removed annually, the growth is not only greatly retarded, but arrested.

In compost, also, we may often see the value of leaves tangibly exemplified, for experience has long assured us that few more really valua-

ble accessions can be made to the compost heap or yard, than that obtained from the forest. In the cultivation of young fruit trees, this species of dressing is now greatly valued. From one to two years are required to prepare them for this purpose according to the particular use to which they are to be applied. Any kind of forest leaves will be found valuable for this purpose. All that is necessary is to afford them time to decompose. The foliage of the alder, bass, poplar, willow and other similar trees, is more readily decomposed than that of the elm or oak; but they possess less consistence, and consequently tend less to the increase of the compost heap.

The fact is now generally well understood by practical agriculturists, that the aliment of vegetables, technically denominated *Humus*, is best produced from that class of substances from which plants derive their food. The process adopted for elaborating this important material is attained in a variety of ways; but the most direct method is by the application of substances of an animal or vegetable character in a state of active putrescence or decay. We of course, are speaking now of organic manures, and in the list of materials shall embrace *leaves*. These, in addition to their organic constituents, possess also matters of an inorganic character no less essential to plants in a growing state, than the former. To illustrate this point somewhat more fully we present an analysis of leaves of the "Early Harvest Apple." The leaves were collected September 30, the tree bearing fruit:

### Temperature of the Earth Under Sod and Under Cultivated Surface.

The writer was recently a listener to an animated discussion between two excellent gardeners. One insisted that the earth was drier and warmer

under sod than under loose earth. The other argued on the contrary. Each was sure the other was wrong, and each appealed to us. "There is a Thermometer, we replied, "why do you not go and try for yourselves?"

How strange it is that men will argue for years on the most simple questions, when but five minutes of actual experiment would often decide the matter at once and forever! How true it is that a large amount of misunderstanding, often leading to the most disastrous issues, not only to individuals, but to whole communities, arises from imagination being mistaken for fact, and hasty assumption misplacing cool perception. In our schools most of what we are taught might come under the head of "what to remember;" but how much better would it not be if the system was "how to observe and consider?" We cannot help making these reflections, as, in our department of education—horticulture,—we find this injudicious course of education opposing our progress at every step. But to the temperature experiment.

It was mid-day on the 26th of August, and the thermometer, in the shade, under a tree, six feet from the ground, was 92 degs.

The first spot selected was in a very hot place, on a lawn, where the grass was kept mowed pretty close by a scythe. A spit was dug up by a spade six inches deep, the thermometer inserted, and the sod placed on immediately. After a few minutes, the thermometer was found to mark 88 degs. Ten feet from this spot, in the same full sunny exposure, was a flower-bed, kept clean by the hoe and rake. The thermometer was here inserted as before, and found to be 96 degs.

A more exposed place was then chosen, on a hill, where a boundary once divided a pasture from a cultivated piece of ground, used as a nursery, on which three-year-old apple trees were growing. Four feet from the fence, in the sod, the thermometer was again tried as before, and the result was 80 degs. The same distance in the cultivated lot, tried in the same way, gave 88 degs.

It was evident from these two experiments, tried in the coolest and in the warmest spots that could be found, that the relative difference in the temperature was uniform, and the result is, that on a hot summer's day, the earth, six inches under surface in sod, was eight degrees cooler than under a clean, loose surface.

It seems to us that this fact, if found to be universally as it was in this particular instance, ought to have an important bearing on the discussion of many important horticultural questions—such as whether orchards as a rule, are better in grass or not, for instance—but it is not our object here to enter into such questions. We wish now merely to call attention to the want of more observations and less opinions, and to show the result of such an experiment in a single instance.—*Gardeners' Monthly*.

### On the Selection of Seeds of the Cereals.

In every field of grain there are to be seen ears differing in size, in form, and in general appearance from those growing beside them. Some of these can be recognised as the ears of established varieties, but a few will be distinct from any of the kinds in cultivation. Farmers usually bestow little attention on the different kinds of ears which may be sometimes seen growing in the same field, and which can be best observed during the cutting and harvesting of the crop; but if one farmer in a thousand would undertake the collection of such ears with the intention of sowing the seed, and thus propagating the kinds, the number of varieties would be considerably increased, and the kinds in cultivation would be improved by this selection of the best ears. Those who intend to collect ears of one or more of the cereals should proceed methodically, not only when selecting, but in keeping the ears of the apparently different kinds distinct at the time of gathering them, so that each kind can be sown by itself, and the produce from the seed of the selected ears collected and stored for future sowing. During the time of selecting ears, small bags formed of cloth should be carried, and as the ears are separated from the stalks they should be placed in one or other of the bags. Care should be exercised to prevent confusion and intermixing of the seeds.

Every circumstance should be noted at the time, such as the field of grain in which the ears were gathered; the characteristic features which the ears presented in growing, such as size, form, whether the ears are close or open, and the color of the chaff and straw, chaff smooth or downy, and other points deemed worthy of being recorded. A written description should be placed with the ears put into each bag for after reference, as it is seldom advisable to trust to the memory as to the facts. The bags containing the ears should be hung in an open place away from mice or other depredators until the period of sowing the seeds.

When it has been determined that the sowing of the seeds of the selected ears shall be proceeded with, a plot of ground near to the entrance of the field can be chosen, the remainder of the field to be seeded with grain of the same kind, whether wheat, barley, or oats. Small ruts can be formed by a hand hoe, the seed thinly sown, and the earth returned by a hand rake, the seed being lightly covered. Each plot seeded should be marked by a piece of wood inserted at the end of the rows and the number marked on the wood for after reference. A note book should be used for inserting all facts connected with the selecting of the ears, the sowing of the seed, the appearance the different plots presented at the period of braiding, tillering, earing, blooming and ripening, with dates and other particulars.

The amount of trouble which the propagating of varieties entails renders it advisable for experimenters not to attempt too much at one time. Only those who are resolved to bestow minute attention during the whole period from the time of selecting the ears until the quantity of grain produced admits of its being distributed, should undertake the selection of ears for propagating the variety. In propagating new varieties, constant attention is essential to keep the variety true to the kind selected, more particularly if it has originated in what is termed a sport, either the result of cultivation or hybridization—the pollen of the ear or one variety fertilizing the seeds contained in the ear of a different kind. This hybridization is sometimes effected by experimenters, but accidental contact is the more frequent cause of the sports which appear in cultivated plants. Every variety of grain in cultivation will occasionally show ears differing from those which possess the characteristic appearance of the variety, while some varieties show red or brown ears, and ears with and without awns. The higher the manurial condition of the soil, the tendency to sporting appears to increase in force. As the soil should be made rich in which the seeds of the selected ears are grown year after year, this tendency to sport is certain to appear, and as the propagating of the selected variety is proceeded with, constant care is essential to cull out the ears which differ from the original standard of the selected ears. If the variety is the result of hybridization, this culling is all important.

The ears will differ considerably in appearance, some resembling the kind from which the fertilizing pollen was derived, and others more closely resembling the variety which the pollen fertilized. Uniformity is essential to entitle any grain to the term variety, and this uniformity can only be secured by constant care in selection. After the type becomes fixed, sporting and degenerating will almost wholly cease, provided ordinary care is taken by the propagator. But every established variety should be kept up by occasional selection of the best ears.

In an industrial point of view the propagating of a new prolific variety of any of the grains is of immense national importance. Any new variety which would yield from one to four bushels of additional grain per acre over the ordinary varieties in cultivation would tend thus far to raise the resources of our own soils. In this direction an extensive and most inviting field is open to all cultivators. Were agriculturists to study more closely the operations of horticulturists, much benefit would result to all. Farmers generally not only undervalue, but wholly disregard what horticulturists have done for agriculture. As well said by the highly distinguished botanist Dr. Lindley, in a recent address to Prince Albert, as President of the London Horticultural Society, "Horticulture, sir

is the parent of agriculture. It determines, on a small scale, the value of the principles on which an extended cultivation of the soil depends."

In garden vegetables, in fruits, in flowers, in shrubs, immense progress has been made within the past few years, mainly the result of propagating new varieties. In all departments of horticulture the exercise of skill and untiring perseverance is apparent, and should be an incentive to agriculturists to follow in the same path.

The pleasure, and in exceptional cases the profit, to be derived is so considerable that the propagator of new varieties will generally be amply rewarded for the time occupied in conducting the various operations of selecting, sowing, and reaping new kinds of grain. Those farmers who are anxious to improve the varieties of grain in cultivation—wheat, oats, or barley, should adopt the same means as some so successfully followed out by horticulturists—hybridizing, and more especially by selecting the best ears, and growing the seed so obtained until sufficient quantities are secured to seed considerable portions of land preparatory to disposing of a portion of the seeds raised from the selected ears. The improvement of the domestic animals and birds has been mainly effected by selection, and the same principles are equally applicable for the improvements of the various varieties of the cereals in cultivation. This field of experiment is open to all, and the persevering may calculate upon success. Where so much can be effected with even an ordinary amount of attention, the experimenter who possesses a knowledge of the cereals, and also of vegetable physiology, is certain to reap a good harvest.—*North British Agriculturist.*

## Agricultural Intelligence.

### The Michigan State Fair.

The *Prairie Farmer* of October 4th observes:

The 14th annual fair of the Michigan State Agricultural Society was held at Detroit last week, and proved a complete success financially, and presented an array of articles and animals in the different departments that entitle it to a fair comparison with the most successful ever held by the society.

The opening day closed with a heavy thunderstorm, quite flooding the grounds and dampening the ardor of the members and exhibitors somewhat, but the second morning broke cool and clear with promise of fine weather which held good. Departments filled rapidly and the people turned out. \* \* \*

The attendance was very large Wednesday and Thursday. Parson Brownlow addressed an audience of about 15,000 on Thursday afternoon, with a recital of personal adventures before leaving Dixie land—he was cordially received.

**Horse Department.**—The entries were not numerous, but enough well-known stock entered to attract great attention. Among them "Magna Charta," "Fanny," a celebrated trotting mare, and many others of local celebrity. Several excellent spans of matched horses were on the ground for carriage and general work. Jacks and mules were more in number and better than ever, showing the attention paid to this branch. The government demand for both horses and mules will tend to remove very many ordinary horses and their place will doubtless be filled with a better grade of stock if we may judge by the feeling shown among horse men and farmers.

**Cattle Department.**—The number of animals entered was large, comprising Devons, Durhams and grades. There were a good many fat cattle, some very noticeable ones. One ox, especially, fed by Mr. Smith, Detroit, weighing over 3,200 lbs. The herd of Messrs. Crouse, of Hartland, in part of imported stock, was very fine, and contained animals of much promise. The Messrs. Sly of Plymouth, noted breeders, had a fine herd. Several others from Ohio and Canada, showed good herds.

**Sheep Department.**—Here, as at Cleveland, the Vermonters appeared in competition with local breeders and growers. The home exhibition was not what Michigan can or ought to have made. The show was made up of Leicesters, South Downs, French and Spanish Merinos. There is a large demand now for sheep, corresponding to the government demand for clothing and want of cotton, and prices have largely advanced the past season. Large prices are offered for fancy sheep. We would caution those desiring to commence to be very careful of whom they buy high priced sheep, that they do not suffer as many in the west have heretofore done.

**Implement Department.**—Anything that will lessen the labour of the farm, and in part make amends for the labor of those who have volunteered, gave this department especial prominence, and the usual number of new inventions, practical and impractical were shown, the proprietor of each demonstrating what fortunes can be made or saved by their adoption. Reapers and mowers were well represented. R. L. Howard, of Buffalo, N. Y., showed the Ketchum Reaper and Mower. The former has a very ingenious simple raking attachment, which the driver can operate with one hand, while he drives with the other, or it can be so arranged as to be worked by the machine—the cost of the attachment is about \$10 for a hand rake, and can be attached to any reaper. He also showed an attachment to the reaper for cutting

up corn. The grain platform and cutter bar is removed, and a shorter one put in its place with a V. shaped hopper for the corn to fall into as cut. When enough for a bundle is cut, it is dropped out upon the ground. It seems as though it would work well. With slight alteration it could be made to attach to most machines.

The Buffalo Agricultural Machine Works had on exhibition the Kirby Machines—the reaper of which had a self-raking attachment, and operated at the will of the driver to lay off bundles of any size, etc. The arrangement was very ingenious. Its cost, attached to the machine, would be from \$25 to \$30. They have been operated only the past season.

*Grain Drills.*—Thomas Mast & Co., of Springfield, Ohio, showed their Buckeye grain drill, with grass seed attachments. The popularity of this drill may be judged of when it is known that they make and sell more drills than any one firm in the States.

Baldwin, Dewitt & Co., of Cleveland, Ohio, also showed the Star Drill, a very excellent machine, and finely finished, its arrangement for seeding insures a very even distribution of seed, and prevents all clogging from foul or dirty seed. Each of last two firms also showed portable cider mills, of which they make large numbers.

*Stump Puller*—Daniel C. Smith, Adrian, the man who used to show a corn-husker at our fairs, has invented and showed here a powerful stump puller, capable of raising 1,000 tons weight with one team, it weighs 3,000 lbs., and is rigged upon a pair of wheels for moving from field to field or stump to stump. It is a combination of pulleys, lever and shears. Complete for use with ropes and chains it costs \$150.

*Farm Products.*—This department was almost totally neglected. A few vegetables, a dozen or so samples of wheat, three or four cheeses, very little butter, a few loaves of bread, are the principal contents; long ranges of tables were entirely empty.

*Fruit Hall* was better filled, but nothing compared to what Michigan is capable of doing. Native grapes were shown by several, together with some splendid lots of the Concord. The Delaware was also shown by some half dozen different ones. The show of Pears was very fair, as also that of apples. This department was under the charge of T. T. Lyon, Plymouth, Mich., a prominent Pomologist of that State.

*Floral Hall* was very finely arranged with a fountain and fish pool, filled with various fishes in the centre, and surrounded with a grass border, as were other departments where plants were bedded in the earth and kept their freshness throughout. Cut flowers were arranged on tables and shelves to good advantage. A part of this building was given up to sewing machines and pictures.

*Manufacturer's Hall.*—The show here was meagre, and embraced but little that was specially noticeable, except the specimens of Saginaw salt which is now attracting so much attention in the country.

The receipts of the Society enabled them to pay their debt, (about \$2,000) pay all premiums, and will leave a fair surplus. This, in war times, was unexpected by many.

### Kerry Cattle.

A correspondent of the *Prairie Farmer*, who has been visiting some of the fine places in the vicinity of Boston, gives some account of the Kerry cattle belonging to Mr. Austin, of Roxbury, purchased for him in Ireland by Sandford Howard, Esq. The original importation consisted of six heifers and a bull; and the herd now owned by Mr. Austin is believed to be the only one of this breed in our country. The exportation of these cattle to America caused quite an excitement in Kerry. The Kerrys are usually jet black, though an occasional one of some other color is seen. Their prominent characteristics seem to be; a hardy constitution, the economy with which they are kept, and good milking qualities of the cows. In size they are about equal with the Jerseys, in form compact and symmetrical, combining the fore quarters of the Devon, with the hind quarters of the Durham. They seem to be well adapted to the farms and cottages of their native country, and if they were common in this country and regarded less as *fancy stock*, they would be well suited to our hilly pastures and severe winters. The writer alluded to above, says:

"They are remarkably gentle, and their hair is uniformly very thick, showing their ability to withstand the severest of winters without shelter.

Mr. Austin has experimented with them upon different kinds of pastures, and expresses the belief that they are emphatically the "poor man's cattle," yet it is likely that they will be monopolized by the rich for some time to come. Whilst I will say they are exactly the breed of cattle for the mountainous pastures of New England, I will also say that if I lived out in the open prairie, had no barn, and could keep but one cow, I would prefer a little black Kerry Cow to all others."

### Sale of Mr. Sanday's Leicester Sheep at Holme Pierrepont.

The great sale of sheep from the justly celebrated flocks of Mr. Sanday took place on Wednesday, and drew together a large attendance of breeders and flockmasters from the Continent, as well as from every part of this country. Mr. Strafford officiated as auctioneer. The pens

comprised 36 rams and 245 ewes, almost all of them either prize winners, or animals which had been highly commended at the principal show in the United Kingdom. This superb flock is now being dispersed over the world. Some of the animals have gone to Australia, others to America. The Minister of Agriculture in Spain has secured several, and in other countries the esteem in which the Sandy breed of Leicesters is held has been testified to by the numerous purchases at high prices which have made at the several sales held at Holme Pierrepont. On Wednesday, large purchases were made for Austria and Prussia. Of the shearling rams, one went to Mr. Princep, of Newton Regis, for twenty seven guineas; another to Mr. Henry Mann, of Lutterworth, for twenty guineas; and a third to Mr. Massey, of Hurlston, for ten guineas; and a fourth to Mr. John Spencer, of Dunnington Park, Melton, for the same price. For a three-shear, Colonel Inge gave thirty-eight guineas; and for another Mr. T. Harris, of Stony-lane, Bromsgrove, gave twenty-one guineas; while a five-shear fell to Mr. Spencer of Clay brook, Lutterworth, for twenty guineas. A lot of five ewes obtained fifty guineas from Mr. Cresswell, of Ashby-de-la-Zouch; another, thirty-five guineas from Mr. Dean Derbyshire; a third, the same figure from Mr. Dabbs, of Seckington; two others, forty-five guineas and thirty-five guineas respectively from Colonel Inge; one twenty guineas from Mr. Dester, of Tamworth; and a lot of four, forty guineas from Mr. Cresswell. A lot of five shearling ewes was knocked down to Mr. Horsfall at eighty-two and a-half guineas, their destination being Koingsberg; another at thirty-seven and a-half guineas to Mr. Hurlburt, for Prussia; and another for eighty-five guineas to Mr. Fortescue, Aberdeen. Summary of sale: 37 rams £688 16s.—average, £18 12s. 4d.; 174 aged ewes, £1,026 7s. 6d.—£5 18s.; 71 shearling ewes, £500 6s. 6d.—average £7 1s.; total sale, £2,215 10s. Average of 245 ewes, £6 4s 8d.; total, £1,526 14s. 72 rams sold July 9, 1862, £1,905 15s.—average, £26 9s. 4½d.

**LORD POLWARTH'S FLOCK.**—This celebrated flock, which has long commanded high prices at the great Kelso sales, and whose strain is distinctly traceable in the flocks of almost all the best breeders of pure Scotch Leicesters in this country, originated in 1882, when 80 ewes were purchased, £2 15s. each, from a well known Northumberland breeder, Mr. Jobson, of Hidgley, near Chillingham, and 140 ewes from a Mr. Waddell (also, we believe, a Northumbrian breeder), at £2 14s. Where the rams were obtained from it is now somewhat difficult to ascertain. At that time, however, the most reputed breeders did not care to dispose of their rams, and it is probable that these were hired from the most famous Border flockmasters, of whom Mr. Robertson, of Ladykirk, was one.

Two years after Lord Polwarth had purchased the flock from Mr. Jobson, he commenced a sale of rams at Mertoun; and from that time, 1804, continued them every year at that place until 1852, when he sent his rams down to Kelso, where they have ever since been sold. This year it will be noticed that his Lordship realized on the average £8 11s. 2d. per head more than Mr. Stark, of Melendean, whose stock made the next highest average. We believe that the esteem in which Lord Polwarth's flock is held is due to the fact that the blood has been kept perfectly pure during the half century he has been a breeder; whereas many other of the border breeders, in a desire to improve their flocks, some ten or fifteen years ago introduced the Cotswold element, with an effect opposite to that intended. We have been unable to obtain the average prices of Lord Polwarth's every year during the fifty-eight they have been disposed of by auction, but the following averages will show how they have been gradually growing in favour; 1830, 35 at an average of £3 15s.; 1840, 46 at an average of £5 11s.; 1853, 40 at an average of £6 18s. 10d.; 1859, 44 at an average of £11 1s. 1d.; 1860, 43 at an average of nearly £17; 1862, 38 at an average of £18.

**SALES OF SHROPSHIRE SHEEP.**—Almost the last, but far from the least important of these ram sales was held on Wednesday in last week, at Grendon, near Atherstone, when Mr. John B. Lythall, the Secretary, of the Birmingham Cattle Show, sold and let thirty-five shearling and five other rams, the property of Mrs. Baker, at an average of nearly £10 each; and also disposed of fifty ewes at 52s. per head, and like number of heaves at 63s.

The annual sale of Earl of Dartmouth's celebrated Shropshire rams and ewes took place at Patsbush on Friday last, and was attended by several of the leading flockmasters of this and the adjoining counties, and went off in a very spirited and satisfactory manner. At one o'clock the company sat down in a splendid marquee, erected for the occasion, to luncheon. At half-past two o'clock the business commenced under the hammer of Mr. Nock (of the firm of Nock and Wilson, Bridgenorth), when ninety store ewes sold, averaging £2 10s.; ninety yearling ewes made an average of £2 3s. The rams also met with good competition, reaching as high as ten and thirteen guineas. Twenty-one were sold at an average of £8 5s.

**AUTUMN SHOW AND GREAT SALE OF TUPS AT KELSO.**—On Friday the Autumn Show of the Union Agricultural Society and the Great Annual Tup Market took place in the Poor-House Field, and was a great success. The prize animals were, as usual, scrutinized with much interest by the farmers present, and it was universally admitted that the awards of the judges were given with the strictest impartiality. During the day the show-grounds were visited by His

Grace the Duke of Roxburghe, President of the Society; Lord Polwarth and the Master of Polwarth, Mr. Grant Suttle, Mr. Prescott, Mr. Coatesworth, of Cowdenknowes, &c., &c. The gentlemen who officiated on this occasion as judges were—for Leicesters, Mr. F. P. Lynn, Mindrum Mill; Mr. Thomas Cockburn, of Menslaws; and Mr. Melvin, Bonnington. For Cheviots, Mr. Clay Winfield; Mr. John Douglas, Tinnis, and Mr. Andrew Douglas, Swinside Hall. The list of premiums was as follows:—Leicester sheep: For the best shearing tup of the pure Leicester breed, Mr. Simpson, Courthill, £5; for the second best, Lord Polwarth, £3; Mr. Torrance, Siserpath, commended. For the best two-shear, Mr. Simson, Courthill £3; for the second best ditto, Mr. Roddam, of Roddam, £2 Mr. Purves, Linton Burnfoot, commended. For the best tup of any age not exceeding four shear, Mr. Simpson, Courthill, £3. For the best pen of five Leicester gimmers or shearing ewes, Mr. Wilson, Haymount, £3. Cheviot Sheep: For the best two tups of the pure Cheviot breed, not above once shorn, £5; and for the best tup of the same breed, not above thrice shorn, £3, Mr. Elliott, Hindhope; for the second best ditto, Mr. Clarke, Ilderton, £2; for the best pen gimmers of the same breed, Mr. Elliot, Hindhope, £3.

## Horticultural.

### Light in Plants.

This light may be classified into two kinds—first, continuous, mostly phosphorescent; second, in the form of lightning.

Decaying wood belongs to the first. A fungus (*Byssus phosphora*, L.) has till lately had the credit for it; but Betzius Von Humboldt and Bishop Argadh (another Swede) agree in ascribing to the wood itself the faculty of shining.

Any kind of wood, if we believe Dessaniges, can get phosphorescent under certain conditions—viz., a proper degree of decay, thermometer 46° to 53°, sufficient dampness and atmospherical air. We find it, however, mostly with alder, beech, white pine, and willow wood. They shine before actual decay, but moisture rules the intensity of the light—the less moisture the less light; no moisture, no light. Where the shining has ceased it can be restored by a little water thrown on the wood, and by enveloping it with paper or canvas.

Temperature, we believe, is of no account so the thermometer does not exceed either the boiling or the freezing point, as in either case the water would disappear.

But not decaying wood alone has this phosphorescence; other parts of plants have it

when decaying. Thus Meyer tells us that, wandering by night through a forest he found decaying mushrooms in a phosphorescent state, and that he took up the shining matter with his stick and rubbed it against trunks of trees.

Tulasne has given us a very interesting treatise about the shining of dead oak leaves. Moisture is in every instance a necessary condition. Of all things, however, it is the diptam which is best known for its remarkable and beautiful light circling round the whole upper part of the plant, when, after warm and calm eays, a match is brought near it. It is the ethereal oil evaporated by the plant which burns, and makes it appear as if the atmosphere round the plant was in a mild blaze. The beauty of this phenomenon is worth trying it, and enduring the failures which an unfit condition of the atmosphere will often bring.

Less strong than the diptam, but stronger than decaying wood, shines the milky sap of *Euphorbia phosphorea*. Martins, during his travels in Brazil, found it to shine mostly when a storm was coming on. He also relates that he was told by the natives of an *Euphorbia* growing in impenetrable thickets of several thousand square feet, which often spontaneously ignite, emit a column of smoke for a while, and ultimately blaze in a clear flame.

But not dead matter alone has this phosphorescent quality. We find it in living plants—for instance, *Rhizomorpha subterranea*, a fungus found on decaying trunks or on timber used in moist mines, emitting light from the tops of its branches so strong that, according to DeCandolle, you can see to read by it; or *Agaricus olearius*, a fungus growing on the olive tree, which shines best when vegetation goes most forward, and which fact Tulasne therefore calls “une manifestation de l’activite de sa vegetation.”

The cause or causes of the phosphorescence of these plants has not been found. A very long range of experiments under all temperatures and at the various stages of vegetation would be required. This explains also why the statements of botanists differ so much—why one has never found that such and such plant has emitted light; why the other asserts that only the lamellæ of different fungi had it, &c. We must, however, here mention a no less interesting phenomenon than either of those already stated. It is offered to us by *Shistostega osmundacea*, a moss growing in caverns and grottoes, which in day-time is in a state of lucidity similar to the *Smaragd*. In this instance the structure of the plant, as the rays of the sun refracted on it, seems to be the cause, though we would not like to vouch for it.

We would rather speak now of the second class of light in plants—namely, where that

light appears in the shape of lightning. And the first observation it appears has been made by Linnaeus's own daughter, Elizabeth Christine, who found that one evening in the year 1762 the orange flowers of *Tropaeolum majus* produced a kind of lightning; that is, the flowers seemed by fits and starts to dash light. She ran to her father, not believing her own eyes; but the phenomenon had disappeared when the father came, and what he had never seen or heard of he would not believe in till he had seen it himself. On subsequent evenings, however, he himself witnessed the fact, whereupon he asked his daughter to make a report of it to the Royal Academy of Sciences. This report has been accepted, and exists on the record. We are sorry that we have to add that neither the great Linnaeus, nor his daughter nor Linnaeus's son, nor any one of a great many chemists and botanists who undertook to study the matter, could to this day succeed in telling us anything better than suppositions, which were hardly uttered before upset by themselves, and amounted to nothing. If the stirring-up of observations, the reiteration of facts, the discussion of probabilities, can ultimately lead the investigating mind to the

true cause, then there is hope for our enlightenment. But as we doubt that, and will not weary our readers, we will, before we conclude this article, tell them that electricity seems not to have anything to do with these phenomena; that orange colour of high intensity and fire seems to have a good deal to do with it; that weak eyesight does not cause it, as Linnaeus naively says, and that besides Linnaeus's daughter, Lector Haggren (also a Swede) noticed it in the year 1788 on *Calendula officinalis*, *Lilium bulbiferum*, and *Tagetes patula* and *erecta*, also, but very slightly, on the orange variety of the sunflower, *Helianthus annuus*. Lastly comes Mr. Fries, and tells us that he was induced to write his essay on light in plants by one night walking about in the botanical garden (in Upsala) and seeing lightning shooting up from an isolated growing plant of *Papaver orientale*, strangely enough after having passed a large group of them without seeing anything; that he then led other persons past who did not know of it, and that he then began to study the light in plants. May he be able to enrich science with the knowledge of its true causes.—*Gardener's Monthly*.

The Hyacinth.

BY MR. WM. PAUL, NURSERIES, WALTHAM CROSS.

Of the many candidates for popular support in the present extended list of garden favorites there are few receiving more attention at the present time than the Hyacinth. Its beauty, fragrance, and variety are so many points of attraction, and the season at which it blooms is worthy of especial consideration. By the appearance of the Hyacinth winter is driven from

its last strongholds, and the garden suddenly rejoices in all the brilliancy of a summer parterre. Then the plant is of such easy culture, that while the highest attainments in the art may be reserved for the patient exercise of skill and industry, the "prentice hand" in gardening may reasonably expect to attain to fair and satisfactory results. In a word, the plant is more manageable than many of its compeers, and hence there is less fear of failure from the oversight of any of those little kindnesses and attentions which the skilled horticulturist knows so well when ad

how to apply. In treating of the culture of the Hyacinth three separate points occur to me:—1. The possession of good bulbs; 2. The season of planting; 3. After culture; and these I shall proceed to discuss separately.

1. **GOOD BULBS.**—The best Hyacinths are imported from Holland. A more beautiful sight could scarcely be conceived than the gardens in and around Haarlem in the spring and early summer months, with their acres of ground, radiant with millions of Crocuses, Tulips, Hyacinths, blue, white, red, and yellow, of the richest and most varied hues, the more grateful to the eye, and the more impressive, because following so closely on the footsteps of winter. As is well known, the culture of the Hyacinth and its allies is a speciality in Holland. I do not see why it should not be the same here, as the differences in some localities, climates, and soils of England appear to me insufficient to account for it not being so. Perhaps our horticulturists are too much occupied with other matters, and certainly it would be commercially unwise to enter the field against such skilful and indefatigable contemporaries without first acquiring a thorough knowledge of so distinct a branch of the art of gardening. We may, and I believe do grow and bloom them as well here as there. But the question remains, can we bring bulbs of *our own growth* into the market of the same quality and at the same price? The answer is, not at present. We can, in the present state of our knowledge and practice, buy and sell cheaper than we can produce.

The Hyacinth being a bulbous plant, the sources of supply, at least during the early stages of growth, depend on the nutriment stored up in the bulb the year before. Thus it will be inferred that it is as important to obtain good bulbs as to grow them well when obtained. And I would here caution the cultivator against placing too much confidence in large bulbs. True, if a bulb is sound, solid, weighty, and well stored with eliminated food, the larger the better; but there are many large, showy, frothy bulbs sold every year in Holland and in England which fail before these tests, and which it requires a practiced eye and hand to apply. Then again, there are some beautiful sorts of Hyacinths—of which Grootvorst is a familiar example—which seldom produce large handsome bulbs. On the other hand, there are some indifferent kinds which generally produce bulbs of great size and beauty. But further, bulbs of the same kind differ in value in the hands of different cultivators. In proof of it we need only adduce one fact—and whether it be attributed to the greater skill of the cultivator or to the superiority of his soil, the fact remains—that there is a difference of 20 per cent. in the prices of the different growers, and the highest priced stock always commands the readiest market. Having laid the foundation of a successful culture by the acquisition of good bulbs, let us pass to the next point.

2. **THE SEASON OF PLANTING.**—The natural period of rest for the Hyacinth is from June to October. If planted before the latter month, the shortening of the natural period of rest diminishes the vigour of growth and the beauty of the flowers. So if the planting be delayed far beyond that period, however well the bulbs may be kept, growth commences, the bulb feeds on the deposit of the previous year contained within itself without the means of recruiting the supply, and a loss of power is the consequence. Plant, then, in the month of October, applying a greater or less degree of heat, according to the season or seasons at which the flowers are wanted. If a very early, a very late, or a long succession of bloom be required, some should be planted earlier, and some later; but the month recommended above is the best, if the finest possible bloom is required, without regard to any definite period.

3. **AFTER CULTURE.**—The culture of Hyacinths falls naturally under three heads:—1, In pots; 2, In glasses. 3, In the open ground.

1. **Hyacinths in Pots.**—It is a matter of no small importance to secure a suitable soil, for although the plant in the first instance feeds on itself, the roots once in action, draw largely from the soil in order to replace the nourishment withdrawn from the bulb. A sandy loam should form the bulk of the soil, but such being usually poor, it must be enriched by a plentiful addition of manure. Cow-dung is the best of manures for the Hyacinth, and it is a good plan to obtain it in a fresh state, mixing it with the loam six months before required for use, turning the whole over two or three times in the interval, that the different substances may be well mixed together. When planting, place the bulb in the middle of the pot, setting it quite upright on a small bed of sand, and so that the apex of the bulb may be half an inch above the level of the soil. Soak the soil with water, and when well drained place the pots, in the first instance, out of doors on the solid ground that worms may not enter. Surround the sides of the pots with cinder ashes, and cover the top with about six inches of the same material. In about two months remove the pots to a cold frame, covering with a mat for five or six days, to avoid a sudden transition from darkness to light. When the mats are withdrawn, give more or less air, according to the season at which the bulbs are wanted to flower, bearing in mind that the more air given the better, provided the frost be completely excluded. The long drooping leaves which we see with some cultivators is due to a too warm or too close atmosphere. So soon as the flower-spike rises, a stiff wire should be passed between the bells the whole length of the spike, the lower end bent outwards till it reaches the circumference of the pot, winding it round the outside of the pot beneath the rim to keep the spike upright and steady. Plenty of water should be given from the time the leaves begin

to grow till the flower shows symptoms of decay, when a gradual diminution should take place. When the leaves turn yellow, water should be entirely withheld, and the bulb should be taken from the pot at the end of July, and stowed away in a dry place for planting in beds the following year. The same bulbs can scarcely be recommended for planting in pots or glasses a second year, but are very good for planting out of doors. Masses of Hyacinths may be planted in ornamental pots or baskets, forming the whole mass of one colour, or the centre and circumference of different colours; and thus ordered, they are at once elegant and effective.

**2. Hyacinths in Glasses.**—Under this form of culture we have in the Hyacinth the most beautiful of house plants in winter and early spring, arriving at the same degree of perfection in town and country. The single kinds, to my eye are always the most beautiful, are especially preferable for glasses, on account of their greater earliness and hardihood. Soundness of bulb at all times important, is more than commonly important here. Set the bulb in the glass so that the lower end, whence the roots are emitted, is almost, but not quite, in contact with the water. Use rain or pond water. Keep the glasses filled up as the water sinks by the feeding of the roots and evaporation. It is a general practice to place Hyacinths in glasses in a dark cupboard or some other place where the light is excluded, and a very good practice it is, for the roots feed more freely in the dark, and thus the system of the plant becomes better stored with food. They may remain in this situation for one or two months, according to the temperature in which they are placed, and should not be too suddenly transferred to the light. Here, as with Hyacinths in pots, when the flowering is over, the bulbs may be brought gradually into a state of rest by the diminution of the supply of water. This done, dry them, store them away, and in due season plant them in beds out of doors to bloom there the following year.

**3. Hyacinths in the open Ground.**—I have never yet seen so much done with the Hyacinth as an out-of-door plant, as I conceive might be done on principles similar to those which have been so admirably carried out in regard to "bedding plants." We have here red, white and blue—to say nothing of the so-called yellow—of innumerable shades. Surely there is ample material for a more extended application of those principles, especially if the aid of the Tulip be called in. The Tulip gives an abundance of yellow, a colour deficient in the Hyacinth. By the combination of these two flowers, a gorgeous and complete flower-garden may be had in spring, as well as in summer, and neither a repetition of the other, but each a change. The Hyacinth is an admirable spring flower. It suffers less from wind and snow, from sleet and hail, than many hardy spring flowers; indeed, almost less

than any other. To-day the snow falls, and the plant is hidden and frozen: to-morrow the sun shines, and it is as erect and as bright as ever.

Hyacinths out of doors should also be planted in the autumn (November). Let the apex of the bulb be placed four inches beneath the surface of the soil, and after the soil is put on, add two inches of decomposed manure as a security against severe frost. In February, when all fear of severe frost is gone, the manure may be removed. The same soil as that recommended for pot-culture is suitable for Hyacinths out of doors. But it may not be generally convenient to remove and replace soil in the flower garden. Well, this is by no means a *sine qua non* of success. We recommend it, but do not insist on it. The convenience of the cultivator must determine the matter. But if a soil be unusually poor, it should be enriched and watered abundantly; if close and heavy, it should still be enriched, and will usually be improved by mixing with it a good proportion of clean road or river sand.—*Extract from Proceedings of the Royal Horticultural Society.*

[The cut placed at the head of this article represents Mr. Tye's newly invented Triple and Hyacinth Glasses, manufacture England, a quantity of which has just been imported by James Fleming & Co., Seedsmen and Florists of this City. They are a highly ornamented production.—EDS. C. A.]

### The Gladiolus.

It is not the least of the recommendations of the Gladiolus as an ornamental plant that it proves to be very accommodating to the soil in which it is grown. That it will flourish in poor sand, and still better if the sand be enriched, is evident from the success which every one knows has been met with by Mr. Standish at Bagshot; but the notion which has been spreading that such deep sandy soils are necessary to it, is by no means confirmed by experience. We are now referring to the Gladioli of modern times, the glorious varieties which we owe in great part to the blood of *Gandavensis*, and which prove so ornamental when growing in the garden, and still more so, if possible, when cut for indoor decoration. These varieties, which have great constitutional vigour, grow well in soils of which Bagshot sand is a type, but they also flourish admirably in beds made up of the compost which accumulates from the emptyings of flower pots wherever a considerable collection and variety of pot plants is cultivated. Moreover they grow to perfection in deep loamy soils, provided they are well drained, and the staple is rendered friable and open by the admixture of decayed manure in a condition suitable to exert

a mechanical action on the mass. Mr. William Paul has rendered this latter fact evident in his new and admirably arranged nursery at Waltham Cross, where the soil being a rather heavy loam—we have seen these Gladioli in a most thriving state, and whence have been derived the specimens with which, though as yet but a limited grower of these flowers, Mr. Paul has won a very respectable position on the exhibition table, and a place in the prize lists. No one, therefore, need hesitate to plant them from any difficulty as to soil.

The question how these Gladioli can be brought to lend their beauties in aid of the general effect at our autumnal flower shows, is one which begins to require consideration and determination now that the growers and exhibitors of them are increasing in number. They do not appear to be quite suitable for pot culture: at least, when exhibited in this form they have as yet proved too lanky, and the plants have not borne a sufficiently furnished appearance. They are admirable flowers for cutting, and in this form doubtless they will be found best suited for exhibition tables. But then how are they to be set up? Are some exhibitors to show single spikes, and others bouquets of each kind, or are bouquets to be required to the exclusion of single spikes? We should say decidedly not, for this would be to give an undue advantage to quantity over quality. Besides, the managers of horticultural exhibitions, besides catering to please their visitors, should at least take care that every part of the institution entrusted to their control should tend to improvement in cultivation; and how can this be the case, if bouquets of the several varieties be permitted to compete with and overpower by mere bulk the single spikes grown by others who are probably more careful if not more skilful cultivators, but who possess less extensive means or less comprehensive collections. Like a Hyacinth, the beauty of a Gladiolus depends in great measure on its well furnished spike, and the size and perfect form of its flowers; but how can these points be expected to tell when a bunch is shown? Nothing, in fact, is well brought out that way but colour, and the sacrifice made by bunch showing in respect to the other qualities referred to is much greater than is compensated for by any gain in respect to a gaudy display of colour. Therefore, we say single spikes should be shown in competitive collections.

But how should they be set up? To begin with, they don't look well to our eyes in ordinary stands and boxes, which do well enough for Roses and Dahlias, but don't seem to suit the Gladiolus. We infinitely prefer the truss set up singly in one of Tye's dwarf Hyacinth bottles, which may be had plain or ornamented, as may be desired; though we imagine those of plain colours would be most appropriate. Then again the cut spike of a Gladiolus, which, be it remembered, looks better of moderate than of ex-

cessive length, provided it is well bloomed, is bare and wanting in relieving foliage. Several attempts have been made to supply this deficiency: the group as a whole has been bordered by various broad-leaved plants to form a background and margin, but broad-leaved plants don't associate well with grassy leaved monocotyledons like the Gladiolus; they look foreign to it, and seem out of place; a few of its own leaves have been sometimes used, as well as sprigs of some of the larger leaved Grasses such as *Poa aquatica*, *Phragmites communis* and the common striped ribbon grass of the gardens; of the Grasses, the best is the *Poa*, but none of them produce so good an effect, at least in our opinion as the natural foliage of the Gladiolus itself.

The result of our own observation and consideration of this subject then is this:—That for exhibition purposes, Gladioluses should be shown in the form of cut spikes; that the spikes should be of moderate and tolerably proportionate length, but above all well bloomed, not with two-thirds or more of their length undeveloped; that they should be set up singly, one spike of each variety; that they should be placed separately in Tye's Hyacinth glass; and that each spike should be accompanied only by a dressing of three or four natural Gladiolus leaves nearly as long as itself.—*Gardeners' Chronicle*.

## Veterinary Department.

(Conducted by A. Smith, V. S.)

### How is the Horse to be put in Condition.

Country gentlemen of humane feelings still fondly cling to the old plan of giving their horses an occasional run at grass. It is so natural, they argue, for the poor things to enjoy a few months of unrestricted liberty to graze on their native prairies, and take such exercise as they please. But, besides such poetical and sentimental recommendations, the run at grass is also supposed to "fine down" and strengthen the limbs, and invigorate the constitution. But to the correctness of these conclusions we seriously demur. Such management may answer well enough as a rest for the over-worked draught horse, but is unsuitable for hunters and well-bred hacks. They gorge themselves with bulky food, get gross and fat, and thus overweight their legs; full of spirit and courage, they gallop and play, running imminent risk of sprains and other lameness, and often come up with kicks and blemishes, and even with damaged wind, from undue exertion taken whilst the stomach has been overloaded. They lose, moreover, their hard condition and their ability to go, and proper feeding and well-regulated exercise must be continued for several months to recover the lost muscle and strength of wind and limb.

For mares and foals, for young, unbroken colts of quiet temper, and for draught animals of more placid temperament, a grass field during the summer is all that can be desired. For hunters, hacks, and the lighter sort of horses that have been in good condition, it is, however, an expensive and dangerous treat.

Horsemen are beginning to appreciate the detriment to the health and constitution, and the waste of time and trouble entailed by allowing their horses, as was the old fashion, to get out of condition when not wanted for several weeks or months. They rightly discover that it is more expensive to turn a horse, after the hunting season for example, to grass, thus allowing him to lose his muscle and strength, and again have him in good order for October, than it would have been to keep him all summer in a comfortable roomy box or well-sheltered yard, allowing him a little corn with his hay and green food, and enjoining daily walking, trotting or other suitable gentle work. The desirability of maintaining horses in continuous good condition becomes all the more reasonable when it is considered that condition, though somewhat of an artificial state, is synonymous with the highest health and vigour. What possible advantage can there be in loading the wiry muscles with useless and cumbrous fat, and weighting the frame as if it was intended for Bingley Hall or Baker-Street? The legs do not suffer as is sometimes supposed, by keeping the horse constantly in fair condition. On the contrary, the carcass being light, the limbs are not overweighted, and like the rest of the body, are also strong, and able to bear their burden. Nothing, we may remark, tends more to shaky, weak, tottering legs than using for fast work horses that are heavy and overloaded with beef, and whose limbs want the toughness and strength which condition alone can give. Although kept during the summer in state fit to go, it is, however, by no means necessary that the animal be subjected to continuous hard work; he need not be galloped or trotted at a "two forty" pace over hard roads. When, like the hunter during the spring and summer months, he is not required for full work, his exercises may be relaxed to an hour or two of walking or gentle trotting exercise, he may be profitably used as a hack, or even for light harness work. A handful of clover or vetches pleasantly vary his diet, and exert besides in a natural way that "cooling" influence on the blood which is so much talked of among stablemen.

Kept in the manner suggested, the horse is at any time in three or four weeks fit for any reasonable moderate work. A little restriction in his hay, a few more oats, his exercise gradually increased, and he will cheerfully and easily perform his allotted work on the road or in harness, whilst with a few preparatory gallops he will not even disgrace his owner if he turns out to the cover side in October. Here the horses

that have run at grass during the summer make themselves unpleasantly conspicuous. The first spurt covers them with lather, heavily they toil over a field or two, boring blunderingly at their fences, and soon give in dead beat; or if senselessly urged along, are apt to sink from congestion or inflammation of the lungs. The muscles of respiration, like those of the limbs and other parts, are weak, and incapable of continued, severe exertion.

To many of our readers it is an important practical question how such an animal can be best rendered servicable. How can his capabilities be most speedily brought to perfection? How can he be prepared so that his duties will be performed easily to himself and satisfactorily to his master? To condition, as to many other things useful and valuable, there is no royal road. The result is to be obtained only by proper feeding, exercise, and grooming. Oats must be the staple food, and with a horse fresh from grass, or that has been living on green food, they should at first be mixed with bran, which will keep the bowels open, and prevent the evil effects which are so apt to follow from a sudden transition from soft, bulky, laxative food to drier and more nutritive fare. From 12 to 15 lbs. of oats, according to the size and appetite of the animal, is a fair daily allowance, and should be given cracked or bruised, not ground, and with a handfull of chaff. For horses intended for fast work beans must be used sparingly, as they are apt to cause indigestion, and interfere with free respiration. Amongst farmers the prevailing dietetic error is allowing excess of hay. The country lad, who often acts as the farmer's groom, is accustomed to see the farm horses' racks filled to overflowing, and acting upon the half true, half false principle that "what is good for the goose is good for the gander," he thinks the riding horses starved unless they have in the rack and under their feet as much hay as would last them for a week. It cannot be too often or strongly insisted on that horses, and, indeed, all animals, should be fed regularly, and should never have more food than they can clear up at once and with relish. From 15 lbs. to 20 lbs. of sound English or good clover hay is a liberal allowance for the lighter sorts of horses, of which at present we are speaking. We would never have a horse restricted in his allowance of water, except for several hours before he is required for work; and to prevent his taking at a time more than is good for him, he should be offered it at frequent short intervals of not less than 5 or 6 times a day. If horses are kept, as they should be, in roomy, loose boxes or commodious yards, regular daily exercise during the summer months, and when not in work, is not essential. But all horses in use, or intended to be used within three months for hunting or other such work, must have daily exercise, which ought to be gradually increased in severity and duration until the horse is cap-

able of performing easily the work required of him. To the discretion of the groom or his master must be left the various questions as to the length of time the horse is to be out, the nature of the exercise, whether he is to go out in cloths, &c. But however these matters be decided, the horse on coming in must be well groomed, rubbed dry, and made comfortable. Where clipping or singeing is practised a rug is advisable; but the loads of clothes often used are useless and injurious, only securing a sleek, glossy skin with less labor to the groom, but at the sacrifice of the poor animal's comfort and health, and with the certainty of rendering him very susceptible of cold. The same, or still more serious, objections attach to the common practice of keeping the stable too warm. For young horses recently taken up from the fields or yard the temperature should not exceed 50, whilst from 55 to 60 degrees will be sufficiently warm for any horses.—*North British Agriculturist*.

### Miscellaneous.

**ANOTHER BALLOON ASCENT.**—THE BRITISH ASSOCIATION.—On Monday, Mr. Glaisher, the superintendent of the meteorological department of the Royal Observatory, made a second ascent from the works of the gas company, in Wolverhampton. As on the first occasion, so also now, the ascent was made in Mr. Coxwell's mammoth balloon, and under the direction of that aeronaut. The instruments taken up were certain of them the same and others similar to those used on the previous ascent, the only exception being that of Thompson's electrometer, which was destroyed in the descent upon the former occasion. That instrument being absent the notes will be confined to the primary observations contemplated by the association—namely, the humidity and temperature of the atmosphere, with its pressure, the vibration of the needle, and how much (if any) ozone there is in the atmosphere away from the earth. About 85,000 cubic feet of very light gas was turned in, and shortly before one o'clock, Mr. Glaisher having shipped all his instruments and arranged them on the board before him, preparations were made to leave the earth. One-fourth of the quantity of gas supplied was let out, with a few bags of ballast, and the signal having been given, the balloon left the earth at two minutes past one, amidst the warmest plaudits from Lord Wrottesley and a large number of the gentry of the neighbourhood. The ascent was a most steady one, the wind was moving about 20 miles an hour in the lower region of the atmosphere, the sky was clear, and the sun was shining brilliantly. The direction in which the balloon was first wafted was south by west, about half a point to the west. On attaining to about 10,000

feet the upper current of the atmosphere was met with; the voyagers then got into a southerly direction; were seen due south, then a point or two to the east; and in about a quarter of an hour after they left the earth's surface they were north by east, about half a point to the east. They then seemed to take their first dip from a high to a lower altitude, and then again to ascend; and it was thought a second dip was made during the time that they were in sight, which was nearly two and a half hours, for so clear was the atmosphere, so immense the size of the balloon, and so slow the motion of the wind, that it was 3 25 p. m. before the machine was lost to the sight of the spectators on the ground whence it ascended. The direction taken seemed to be over Birmingham, and towards Coventry. Great interest is felt in the experiments now being made, the results of the previous experiments being, in many respects, contrary to all views hitherto entertained on the points of meteorology that are now being investigated. For instance, a cloud one mile thick was passed through on the first occasion, without there being any dew deposited on the most sensitive hygrometer, and no ozone was found in the air, notwithstanding that, in experiments on the earth, the most ozone was found at the high altitudes. For the experiments of Monday, ozone papers were specially made by Dr. Moffat himself. The balloon descended at five minutes past four o'clock, at Solihull, 25 miles from Wolverhampton, after attaining a height of four and a half miles, where the temperature was 24 degrees, the barometer about 13 inches, and the dew point minus ten.

**A SKYLARK PREACHING A SERMON.**—There is no such thing as a song-bird in Australia; there are birds who chatter, birds who shriek, but no birds that sing. Well there was a young man who went from England as a gold-digger, and was lucky enough to make some money, and prudence enough to keep it. He opened a "store"—a kind of rough shop where everything from candles to coffins are sold—at a place called "The Ovens," a celebrated gold-field, about 200 miles from Melbourne. Still continuing to prosper, he, like a dutiful son, wrote to his father and mother to come out to him, and if they possibly could, to bring with them a lark. So a lark was procured, and in due time the old folks and their feathered charge took ship and departed from England. The old man, however, took the voyage so much to heart that he died; but the old woman and the lark landed in sound health at Melbourne and was speedily forwarded to Mr. Wilestead's store at the Ovens. It was on Tuesday when they arrived and on the next morning the lark was hung outside the tent, and at once commenced piping up. The effect was electric. Sturdy diggers—big men, with hairy faces and

big brown hands—paused in the midst of their work, and listened reverently.—Drunken, brutal diggers left unfinished the sentence and looked bewildered and ashamed. Far and near the news spread like lightning—"Have you heard the lark?" "Is it true, mate, that there is a real English lark up at Jack Wistlead's?" So it went on for three days, and then came Sunday morning. Such a sight had not been seen since the first spadeful of golden earth had been turned! From every quarter—east, west, north, and south—from far hills and from creeks twenty miles away, came a steady concourse of great rough Englishmen, all brushed and washed as decent as possible. The movement was by no means preconceived, as was evident from the half-ashamed expression of every man's face. There they were, however, and their errand was to hear the lark! Nor were they disappointed. There, perched in his wooden and iron pulpit, was the little minister; and as though aware of the importance of the task before him, he plumed his crest and lifting up his voice sang them a sermon.

It was a wonderful sight to see, those three or four hundred men; some kneeling on the ground; some sitting with their arms on their knees, and their heads on their hands; some leaning against the trees with their eyes closed, so that they might the better fancy themselves at home and in the midst of English corn-fields once more; but sitting, standing and lying, all were equally quiet and attentive; and when, after an hour's preaching the lark left off, his audience slowly started, a little low-spirited, perhaps, but on the whole much happier than when they came.—*Boston's Home Pets.*

### Hints for October.

October is one of the most active months in the year with the gardener, orchardist, and nurseryman. A multitude of labours demand simultaneous attention, and it requires the most untiring energy and industry on the part of every one who has any considerable charge on his hands to see that every thing is done at the proper time and in the proper manner. Fortunately, in this country, our October weather is delightful—dry, cool and bright, generally, and therefore eminently favorable for the rapid and proper execution of all out door work.

Transplanting of all hardy trees, shrubs, and plants usually begins here in the north about the 1st of October; further south it must be deferred later. It is by no means necessary to wait until the leaves have fallen. If growth has fairly ceased, and the wood has become firm, trees may be removed; the leaves must be taken off to prevent shrivelling, and the roots must be carefully guarded against exposure until they are again placed in the ground. Autumn planted trees should by all means be secure against the

winds, either by staking or banking up, and they should be well mulched besides.

Neglected orchards should be renovated by manuring and ploughing or spading about the roots. This should never be deferred till spring because during the winter and spring the sod decays and the manure dissolves, and abundant food is thus prepared the trees next season.

Kitchen and garden crops for winter and spring use require nice management to keep them in a proper condition. Such as are taken up and placed in the root-cellar should be handled when dry, and the cellar should be clean and sweet, and perfectly free from moisture both above, and below; it should also be kept cool as possible, but not admit frost.

Such of the bedding plants as it is desired to save for another season, should be carefully lifted early, and either potted or planted closely in boxes, and placed where they will have light, and not freeze. Many of the bedding plants, if taken up carefully and in good season, may add materially to the beauty of the green-house through November! Many of the late flowering annuals are useful in this way.

Hardy bulbous roots should be planted immediately, yet it can be done any time before the ground freezes. There are certain things that vegetate early in spring, and should therefore always be planted in the fall, such as gooseberries, currants, rhubarb, and all hardy spring flowering shrubs and herbaceous plants. A good bloom next spring may be secured by planting now, but will be lost if the planting be deferred till next spring.—*P. Barrey.*

**ANIMAL INSTINCT.**—I knew of a jackdaw that often used to eat the gum that exuded from plum trees, and always did so when it was well. In connection with this subject, it may as well be mentioned that a careful observer would find himself repaid by watching the modes of cure employed by sick or wounded creatures. We all know that the dog and cat resort to grass when they feel out of health, and hares to a species of moss. I was also told, on the authority of the eye-witness, that a goldfinch, which had been struck by a hawk and wounded, made its way to a dry puff-ball, tore it open with its beak, and dusted the wounded shoulder with the spores, thereby stopping the effusion of blood. The spectator was greatly surprised at this incident, and being induced to try the effects of the same remedy upon a wounded finger, found that the experiment was completely successful.—*Routledge's Illustrated Natural History.*

**CHLORIDE OF LIME AS AN INSECTICIDE.**—In scattering chloride of lime on a plank in a stable, all kinds of flies, but more especially biting flies, were quickly got rid of. Sprinkling beds of vegetables with even a weak solution of this salt effectually preserves them from the attack of slugs, caterpillars, butterflies, mordellas, &c.

It has the same effect when sprinkled on the foliage of fruit trees. A paste of one part of chloride and one-half part of lard, placed in a narrow band round the trunk of a tree, prevents insects from creeping up it. It has been noticed that rats and mice quit places in which a certain quantity of chloride has been spread.

### Editorial Notices, &c.

#### Agricultural and Veterinary Instruction.

Arrangements are being made for opening a class of young men for the study of the Veterinary art and the principles of agriculture, in Toronto, under the auspices of the Board of Agriculture, to commence about the middle of January, and to continue for five or six weeks.

Mr. Smith, a licenciate of the Veterinary College of Edinburgh, and Veterinary Surgeon to the Board of Agriculture of Upper Canada, will give instruction in the anatomy, physiology and diseases of the Horse, and farm animals generally, and Professor Buckland, assisted by the Professors of Chemistry, Geology, and Natural History in University College, will take the various branches of science that relate to the practice and theory of agriculture. It is hoped that a considerable number of young farmers from different sections of the country will avail themselves of such an opportunity of improving themselves in a knowledge of the principles of their important art. Full particulars hereafter.

## DUTCH FLOWER ROOTS.

THE SUBSCRIBERS BEG TO ANNOUNCE that they have just received their annual importation of Bulbs in good condition—consisting of *Double and Single Hyacinths*, \$1.00, \$2.00, and \$3.00 per dozen. A fine assortment of *Tulips*, from 50 cents to \$2.00 per dozen. *Crocus*, 12 to 20 cents per dozen, and at \$1.00 and \$1.50 per 100. *Polyanthus*, *Narcissus*, 12 to

15 cents each.

Descriptive Catalogues furnished gratis on application. They would also call attention to their fine stock of English Hyacinth Bottles, with supports, suitable for growing Hyacinths in winter, and for holding parlour bouquets in summer. (See above cut.)

### JAMES FLEMING & Co.,

Seedsman and Florists, Corner of Yonge and Queen Streets, Toronto.

Toronto, Oct. 27th, 1862.

tf.

**Horse Infirmary and Veterinary Establishment**  
**Corner of Bay and Temperance**  
**Streets Toronto, C. W.**

A SMITH, Licentiate of the Edinburgh Veterinary College, and Veterinary Surgeon to the Board of Agriculture of U. C., begs to return his thanks to the Public generally for their support since opening the above mentioned establishment, and respectfully solicits a continuance of the same.

And also begs to announce that Veterinary Medicines of every description are constantly kept on hand:—Such as, Physic, Diuretic, Cough Cordial, Tonic Condition, and Worm Balls and Powders. The constituents composing the Cough-balls, have been found (by Professor Dick, of Edinburgh) most serviceable in alleviating many of the symptoms of Broken-wind or Heaves in Horses. Colic Draughts, &c., a mixture which owners of Horses should always have beside them.

Liniments for Sore-throat, Sprain, Curb, Spavin, Ringbone.

Blistering Ointments. Liquid and sweating Blisters.

*Horses bought and sold on commission.*

Toronto, Aug. 30th, 1862.

No. 22.

**Excrements of Poultry as Manure.**

It has been known at least from the times of the ancient Romans, that the excrements of domestic fowls, and birds in general, possess highly fertilizing properties. A thrifty farmer will, therefore, carefully preserve the dung of his poultry yard and pigeon cots, and apply it, mixed with earthy matters, as a dressing for his cultivated crops. As the feces of birds are discharged through a single aperture, they possess the combined properties of both the solid and liquid excrements of other animals.

Poultry dung is one of the most powerful manures; and is, therefore, worthy of greater consideration than is generally bestowed upon its collection, especially as it so soon decomposes, and consequently loses so much ammonia; and it would lose a still greater quantity of that gas, did the excrements not dry quickly, and thus prevent a further decomposition of the urea. The strongest are those of pigeons and domestic fowls—a fact easily explained by the circumstance of their living chiefly upon grain, insects, and worms, while geese eat grass also. That we may lose none of the ammonia developed during the putrefaction of poultry dung, we should do well to strew the yard and house in which they are kept, with soil abundant in humus, for then the ammonia of the manure will be combined with the humid acid of the earth. The strewing of the ground with sand, sawdust, &c., as commonly practised, is in this point of view, of no use whatever.

The excrements of pigeons were carefully ex-

amined by Mr. Humphrey Davy, and Sprengel. Davy found in 100 parts by weight, 23 parts of substances, soluble in water, consisting of urea, urate of ammonia, common salt, and some others. According to the latter, pigeon-dung half-a-year old contained only 16 per cent of bodies soluble in water, consisting of very little urea, but of a large proportion of carbonate sulphate, and humate of ammonia, common salt, and sulphate of potash. The other 84 parts insoluble in water consisted of coarse siliceous sand, silica, phosphate of lime and magnesia, traces of alumina, and oxides of manganese and iron. The abundance of soluble substances explains the quick effect of pigeon dung, and also shows us once more the great value of mineral manure.

When the droppings of geese come in contact with the grass in pastures they destroy it in a short time, so that farmers do not readily allow geese to have access to pastures; not to mention that, when the herbage is rendered foul by the excrements of these poultry, it becomes loathsome to other animals. The speedy injury inflicted on plants by goose-dung is occasioned partly by the uric acid it contains, and partly by the ammonia which is so soon generated and developed on decomposition. When rain happens to fall, these caustic substances are diluted, and the grass grows the best in places where the excrements lay, as may be seen in any goose pasture.

As poultry dung is very rich in powerfully manuring matters, easily soluble in water, it should be applied only in very small quantities; and, in order to affect its due distribution

as it is generally dried strongly together, it must first be reduced into a fine state by thrashing, or other means. In Belgium they employ it particularly for manuring their flax, and calculate the annual value of the dung of 400 or 500 head of pigeons at 25 or 30 rix-dollars, (about £5 or £6 sterling). Poultry dung must always be used as a top-dressing, or only harrowed in very lightly; and it should be spread over the ground when there is no wind: we should generally choose damp, but not wet weather, for the purpose, otherwise the many soluble substances would be carried too deep into the soil, or washed away altogether. If a meadow be manured with poultry dung, and sheep driven on it soon afterwards, it is almost entirely eaten bare by them, probably on account of the many salts, including common salt, contained in this manure. Like all other manures containing much ammonia, it soon destroys moss in meadows. When it is wished not to employ poultry dung by itself, it will be found best to mix it into a common heap with some soil rich in humus; a soil of this kind should be used with all organic remains containing much nitrogen, as all loss is thereby prevented. How much, however, of this invaluable manuring substance (nitrogen), in the state of ammonia, is every year wasted on all farms, it is impossible to say.

To the excrements of birds belong also the dung of the cormorant or gull, which occurs in immense quantities on some islands lying off the coast of Peru, and is named Guano. It is used in Peru with the most striking effects in manuring the maize-fields. Vanquelin and Fourcroy, who undertook a chemical examination of the "Guano," found it to contain 25 per cent. of urate of ammonia, and urate of potash, as well as the phosphates of potash, a fatty substance, and some silica. According to Klaproth it consists, on the contrary, of much humate of ammonia, common salt, phosphate of lime, some animal remains, and sand. More minute subsequent remains have shown that guano is very variable in its composition, from differences both of climate and situation.

### Vice versus Labour.

Under the above heading we find in a recent number of the *Mark Lane Express*, an excellent and highly toned article on the moral and social condition of the cultivators of the

soil, signed 'A MAN O' THE MEARNS, from which we select the following extract, the length of which will be justified by the importance of the truths enunciated, and which are of universal application:—

In all ages and in all kingdoms of the world, *vice* has proved itself diametrically opposed to *labour*, and for the most cogent and tangible reasons will of necessity continue to do so to the end of time. Virtue, industry, and wealth, whether viewed in an individual or in a collective or national light, have always been considered synonymous terms; and so have immorality, idleness, and poverty. Such is Nature's irrevocable fiat, pronounced against every race and against every social rank of the human family. Neither kings nor queens, peers nor parsons, are excepted any more than country squires, farmers and agricultural labourers. Wherever we find virtue or vice, whether in the palace or in the cottage, there we are also sure to find their respective awards in some form or other. We may as well think to gather figs of thistles as to realise the contrary. Indeed, it is well for mankind that it is so; for had the reverse been true, the heart recoils from the contemplation of what would have been its inevitable consequence.

There is, perhaps, no branch of industry where immorality is attended with more ruinous results than in agriculture, more especially amongst the labouring population; consequently there is no place where virtuous habits ought to be more sedulously cultivated, both by precept and example, than in the cottage of the agricultural labourer. We repeat, *both by precept and example*; for if landowners and their factors (stewards) and tenants spend immoral lives, it is hopeless to think of a virtuous, industrious, and prosperous peasantry.

The reason why immorality is attended with results so adverse in agriculture arises from the heavy character of the work and the fidelity with which it must be executed in order to obtain from the soil abundant crops, such fidelity being incompatible with loose, immoral, and vicious habits. There are, no doubt, "roughs" who will go through a vast amount of work in a short time, if you will only give them drink, or in some way or other bribe them to do so, and then look sharp after them; but "fits and starts" of this kind are always attended with shortcomings, that do far more than counterbalance any benefit derived from them, while such work can never be performed as it otherwise would be, consequently it is never followed by the same train of propitious results. In other words, "the blessing of an Overruling Providence never has attended such a system of things, never will do so; for although fruitful seasons are given to both good and bad, yet we have Divine authority for the conclusion involved in

the above characteristic difference (Lev. xxvi. 33, and Isaiah i. 19, 20)—a difference involving the violation of Nature's laws and its never-failing punishment, as we shall now proceed very briefly to show.

*Immorality is ruinous to both body and mind.* Those who indulge in vice of any kind are guilty of a species of self-destruction; for apart from the momentous question of everlasting punishment in a world of spirits, they impair their physical and intellectual faculties during the currency of their lifetime on earth, while they greatly shorten the mortal period of its duration. The nervous, muscular, and osseous systems are soon broken up, and rendered unfit to perform their respective functions in the animal economy; and as a natural consequence, the body of the agricultural labourer becomes less and less able to execute its daily task. Thus the nervous tissues become relaxed, and consequently they lose their natural tone. The sensual pleasures of the voluptuary cease to be relished. And were this all, the loss would be small; but the nerves have other functions to perform than those connected with the senses: for it is now an established fact that all those processes in connection with digestion and the nutrition of the body are greatly dependant upon the healthy action of the nerves, while all the muscles of the body, voluntary and involuntary, are entirely under their control, so that when the former cease to perform their functions, so also, of necessity, must the latter. But the tissues of the muscles also become relaxed, and thereby lose their contractile powers; so that the labourer, by immorality, not only sacrifices his muscular strength, so essentially necessary at all the heavy work of agriculture, but the muscles of the heart, and all the involuntary muscles engaged in the performance of the other vital processes, also lose their contractile force, consequently they cease to perform their functions normally. Hence the prostrate condition of the labourer after a night's debauch, and the rapidity with which infirmity of every kind overtakes him—even the withering hand of old age before he reaches the natural meridian of life.

With regard to the intellectual faculties of the mind, they also become impaired in a similar manner; the professional skill, judgment, discrimination, memory, &c., of the agricultural labourer becoming of a lower and lower standard as the physical system is broken up by immorality. It is now an established fact that, in the cultivation of the mind, as in the education of youth, the body must at the same time be physically trained before successful results can be realized. And just so in the *vice versa* philosophy; for if you lower the standard of the physical functions, you at the same time lay prostrate with them the more ennobling faculties of the mind.

Such is the very general outline of the effects produced upon the body and mind of the agri-

cultural labourer by immorality. In many respects, the details are of a nature such as to prevent their discussion, practically, in the columns of an agricultural journal. The subject divides itself into three heads—the physical, the intellectual, and the religious, or spiritual; and these, in practice, can and ought never to be separated the one from the others; for their combined action is essentially necessary to make the cottage of the labourer virtuous, industrious, and happy; and therefore each of them requires to be thoroughly understood, and brought home to every cottage hearth, as a practical question of daily life, for professional consideration. No doubt, in a purely professional light, the skill and the handicraft of the labourer, or the science and practice of his profession, are mainly included in the former two; but in the reformation of the morals of the people religion cannot occupy a secondary place in the cottage of the poor man, any more than in the palace of the prince; for according to the purity of the religious standard, so will be found the morality of the family, high and low, rich and poor.—Now as the physical and intellectual standards are dependent upon the moral, as has already been shown, the importance of religion is manifest. Much is now being said about the low standard of morality in Scotch bothies; but, unfortunately, this low standard is not confined to bothies, and the bothy system did not arise until a falling-off of religious principle and morality was first experienced. So long, for example, as the farm-servants of the father of the writer attended and respected family worship regularly every night, there was no clamour for a bothy: but when they began to sneer at the “Big-Ha-Bible” and those who kept family worship, and to absent themselves on Sunday evenings, so as to avoid being examined, or as Burns had it, “targed tightly,” on the “Shorter Catechism,” and thus have their ignorance of religious truth exposed, and otherwise to live an irreligious and immoral life, nothing would satisfy them but “a bothy and their meal,” and as their conduct in the kitchen could no longer be tolerated, a bothy was consequently built for them. And now that a revival of religion has taken place, and that family worship is again beginning to be respected by all, and cherished by very many, in the castle, farm-house, and cottage, this vital work of Grace is beginning to produce its legitimate fruits, so that the moral work of reformation thus begun cannot fail, in due course of time, of extending itself to bothies, when the more thoughtless unmarried labourers, male and female, wherever they live, will be obliged to succumb to the authority and example of the better-behaved. As yet, however, it is no easy matter to select virtuous, intelligent, and industrious farm-servants; and this is equally true, whether they are married or single. At the same time a separation of the sheep from the goats is evidently taking place in every rank of society,

both in town and country; and the labourers of the present day are not such bad characters as they were some time ago, or when bothies first began to be the common plan.

## Application of Chemistry to Agriculture.

[TRANSLATED FROM THE FRENCH.]

"The application of chemistry to agriculture has been attended with results unquestionably beneficial to that science. True, there have been some disappointments, but they proceeded chiefly from expecting too much of the science, or from a wrong interpretation of its laws. In making use of figures which result from analysis as correct indications, when they ought not to be taken in their absolute terms; in taking account of the multiple circumstances which tend to modify the principles of chemical reactions when they pass from laboratories into the heart of arable land, owing their effects to contact with the roots of plants, we throw great light on agricultural operations, and, in the end, reach a production more economical and abundant. For this reason the names of Bossingault, Payen, Lawes, Gilbert, Way, Anderson, and many others have become popular amongst the cultivators of France and England; but in Germany another chemist has gained by his labours and writings great fame, and has retained it throughout the whole of Europe. A little adventurous, and apt occasionally to be carried away by his imagination, M. Liebig—now one of the eight foreign members of the Academy of Science of the Institute of France,—has upon several occasions, given to agriculturists advice which does not appear to bear the stamp of prudence. In chemical agriculture experiments out to be conducted with wise deliberation. It costs too much to leave unrestrained a new system; but setting aside some too-determined efforts, which have only ended in disappointment, M. Liebig has written many good works, so that one ought to listen to him with respect; besides, one may learn much, by reading his numerous writings, beyond what is attached to the subject, from the lively and masterly manner in which it is treated. M. Liebig published for the first time about 1846, a series of about twenty-six letters on chemistry, as applied to manufactures, physiology, and agriculture. In 1851 he added eleven new letters to the preceding ones. This second series was translated into French by a chemist who died young, but who left a name illustrious and regretted—Gerhardt. We have now received a series of fourteen letters upon modern agriculture, of which Dr. Swartz, professor of chemistry to the University of Ghent, has given a good translation. We find in them many excellent principles, but also some points very disputable: thus a strong pleading in favour of mixed manures, and against the exaggerated use of simple manures, is worthy of all approbation;

but the absolute condemnation of the commercial culture of tobacco and the vine appears to us far from the limits of truth. But however this may be, the theories of M. Liebig ought to be considered by agriculturists; for this reason we recommend them to read his new letters (a volume of 264 pages, price three shillings). In addition we think it would be useful to publish two lectures, delivered the year after, at Munich, and an estimate of his doctrines, which we received from our contributor, M. Adam Muller, deputy to the Diet of Bavaria, and connected with the illustrious chemist of Munich.

In the first lecture will be found a very interesting note on the school founded by Thaer, from Moeglin; but also a critique, rather too severe, upon agricultural instructions—such at least as have been given in some places. M. Liebig cannot combine, in the same institution, practice with theory. He says the two instructions ought to follow one another, and that it is necessary to be well versed in the theory before commencing the practice. We reciprocate this opinion. The Agricultural Institute of Versailles would have been perpetuated if farms had not been annexed to it. The pupils, in leaving the institute mere theorists, would have been with advantage sent on to good farms, in this country or others, to complete their instruction afterwards as the pupils of the Polytechnic School, in the schools of application, and, above all, in the great public works, where they continue their studies before becoming masters.

M. Fouville translated the first lecture, and our learned contributor, M. Villeroy, very willingly translated the second, which is entirely devoted to the methods introduced by chemistry into agricultural science. It contains an excellent discussion upon the means of keeping up the fertility of the soil, on the importance of artificial and commercial manure, and the absurdity of losing the cleanings of towns. In his article M. Adam Muller gives a summary of thoughts of M. Liebig, such as occurred to him in a long attendance on the course of the learned chemist.

J. A. BARRAL.

### LECTURE I.\*

By BARON JUSTUS VON LIEBIG.

We celebrate the day on which, 102 years ago, the Elector Maximilian Joseph III. signed the constitutional patent of our academy. This event took place in that age so memorable for the history of sciences, when the foundation of the major part of the academies of Europe—those of Berlin, St. Petersburg, Copenhagen, Lisbon, and Dublin—showed the effect which a strong impulse had produced on the development of European mind.

\* Delivered at the session of the 26th March, 1861, for the celebration of the 102nd anniversary of the foundation of the Academy of Sciences in Munich.

In England and France they broke the trammels which hindered the culture of intellect, and in every country of the world the desire was felt to take part in the movement begun, of making useful to the people generally the riches of the intelligence newly acquired. In Bavaria, as elsewhere, was found a nucleus cultivating the sciences, but without power to give them any influence whatever upon life. The patriots who had the courage to propose a change in this state of things had to strive against difficulties on all sides; for a false science of nature, and errors which had become popular, had taken possession of the soil in which ought to have been implanted the new truths. Without extirpating old notions, those which should be popular evidently cannot take root.

To the names of Lori and Linprun is attached the imperishable honor of having commenced the struggle of light against darkness. These learned men conceived the idea of forming, with the aid of a few others, animated by the same noble sentiments as themselves, a society for the purpose of cultivating the sciences, devoting itself to their extension, and struggling against ignorance and superstition. For this purpose their design was, to commence by accomplishing what would be necessary for the well-being of the country, and practicable at that epoch. They had first to level the soil, and thus open a way for scientific discoveries. From the heart of this union of learned men, the majority of which was composed of ecclesiastics, came forth the project of founding an Academy of Sciences. When the Elector of Bavaria had signed the patent for its commencement, the issue of the battle no longer remained uncertain. The victory for truth was henceforth assured. On forming the Academy it was publicly declared that liberty of progress existed then in Bavaria, for the academical writers were free from all censure other than that exercised by the body itself. This act declared that ignorance and superstition was only a necessary evil, and that in seeking to battle with it they would render service to the state.

In conformity with the idea which animated the founder of the Academy, the labours of its members were confined principally, during the first period, to the geography and history of the country, the study of language, and alteration in the system of schools. A taste for the study of mathematics was particularly insisted on by the professors of the Academy, and a fundamental knowledge of the most general phenomena was encouraged by treatises on natural philosophy.

Whilst the law of 1759 indicated but one aim for the labours of the Society—"the diffusion of all useful sciences and liberal arts in Bavaria"—the constitutional ordinance of 1807 went a step farther. Not only ought the members to propagate scientific knowledge, but in addition, by reflections, researches, observations, and

other labours, new results would be introduced into the domains of science; while those already known would be rendered more useful.

At the time of its foundation, numerous practical questions which each understood had acquired a certain importance, and deserved to occupy the minds of these scientific men, so that every one was compelled to admit the utility of academical work, when, in conformity to its constitution, it employed itself with agriculture, hand labour, mineralogy, and metallurgy. Even the constitution of 1807 returned thanks specially to the members who would find means of improving agriculture, stimulating industry, and above all, destroying the prejudices which opposed the progress of manufactures.

In the organic law of 1827, with which commenced the current epoch, the members were particularly recommended to occupy themselves with the solution of problems of a practical nature. The Academy became "an association established under the protection of the King for cultivating the sciences, and extending knowledge by means of researches and collective works which are beyond the reach of isolated individuals."

It appears, in consequence, the Academy pursued another aim besides that of its foundation. Whilst it was at first merely an organ of enlightenment, an association occupying itself with certain material interests of the country, the members of the second period joined to that aim the conquests of fresh results, and those of the current epoch occupied themselves exclusively in extending the domain of science.

In reality, there was no contradiction in these different aims; they expressed only the idea, formed at different periods, of the influence of science on public prosperity. A hundred years ago it was thought that science could only operate upon the development of the material interests of the country, but now we know that science is merely useful because it develops the intellectual power of man—an advance which is a condition nearest to the development of agriculture, manufactures, and commerce.

Assigning a practical aim to the works of the Academy was not worthy of that body, nor beneficial to that which they proposed to do; and this error caused to be called in question for some time the utility of the institution. The labors of the academicians would necessarily lose their true and important signification with the mass of the population, because they estimate their value by the nature of the services they have rendered to the agriculturists and workmen of Bavaria. The special nature of the researches was not calculated to supply the particular wants of each. The perfecting of an implement, a receipt for improving the soil, the preparation of soap, a method of dyeing a stuff, or tanning of leather, would be useful to one manufacturer, agriculturist, soap-boiler, dyer, or tanner, but not to all who were engaged in the same trade. Dif-

ferent manufacturers would have different tools to perfect; one farmer would require a different manure from another; all soap-boilers do not make the same soap; a dyer would require one colour for silk, another for worsted. In fact, each tradesman has, for the improvement of his art, some special wants which vary indefinitely according to his experience or degree of competency.

A society of scientific men cannot undertake to answer the wants of each individual; their efforts must be directed in a manner that will benefit all classes. For instance, it cannot occupy itself in perfecting implements of the industrial routine; it must search out principles which will conduce to practice.

With this latter view, our Academy has taken considerable in the progress of mechanics, manufactures, and technical arts. If ever complaints are made against its utility, they should be directed, not against the academicians themselves, but against the manufacturers and technologists who refuse to take part in their labours. If they have not done it yet, or have done it in an imperfect manner, that arises from there existing no real union between practice and science.

In order that two men enter into an intellectual treaty with each other it is indispensable that one speaks the language of the other; but not long ago the practitioner resembled a slave, who can only comprehend the language of signs; for he only recognized as true and real that which was visible and comprehensible: progress could only reach him indirectly. The practical man challenges the scientific to erect a theory on that which his reason suffers him to comprehend, and despises as purely speculative and impracticable the conclusions and lessons of science. Practice and not theory, is with him the true professor. "How can men who do not know how to manage a plough tell us what fields require, to produce a good harvest? or how rain acts on the growth of fruit?" This was for a long time the language of the practitioner.

It must be admitted that in general a theory only, does harm to the practical man every time he tries to put it in use; the attempts that he hazards produce results opposed to those that he looks for. He does not even know that the use of a theory is not a gift natural to man, and that he should be taught it just the same as he would learn the use of a complicated instrument. He does not know that the legitimate use of a law for a given case supposes the intelligent comparison of all specific circumstances, and that intellectual work supposes a series of operations in which it has no guide. In order that a theory can be made of use to him, he must give it due reflection, discern its property, in fact learn to make an exact observation. The abyss between science and practice begins to be filled up successively, thanks to the wise princes who possessed the will and power to break down the obstacles which prevented

the development of the intelligence of the people, and who by improving the system of schools and other means of instruction have extended knowledge among all classes of the population; their names are intimately connected with all the improvements that the state of civilization and culture of the mind permitted to be accomplished; they have gained immortal honour untarnished by blood or tears. In every country prosperity, riches, morality, and real power increase with the amount of knowledge that the people acquire. Is it not, in fact, the extension of knowledge which destroys the prejudices proceeding from primitive ignorance and paralyzing the expansion of individual force? Is it not a deeper knowledge of things that gives us our laws, our inmost convictions, our customs, the commodities of civilized life, our arts, sciences, and manufactures?

The progress which has been made in schools, and other means of instruction, during the last fifteen years, is in reality greater than that of several preceding centuries. The education of the workman, manufacturer, technologist, merchant, the labourer, is no longer comprised, as formerly, of a lecture on writing and the four rules. Not only in our gymnastics and industrial schools are the faculties of the mind developed in such a manner, as that young men who leave them are fitted to accomplish the most complicated intellectual operations; but, further, it gives to the pupils a great amount of knowledge, by the help of which, without more attention, more order, or more activity than their fathers, they can undertake more difficult tasks, and perform them in a more satisfactory manner. In fact, this is the principal result of the education they receive—the young men learn to comprehend the language of science, and acquire in consequence the advantage of bringing to bear upon the wants of life and society, the discoveries which they make by its study.

It is worthy of remark that this improvement is universal in all spheres of society; in fact, the idea that a little of science is useful under all circumstances, even to the poor workman, is beginning to take root even in the minds of men who have had no occasion to follow the professed course in schools. We generally believe that some scientific knowledge of botany is useful to the gardener—that the baker, the soapboiler, the tanner, and the dyer, would feel, in the practice of their art, the want of possessing some knowledge of chemistry. One gardener is not worse than another because he comprehends better the life of plants; a baker is not the less useful because he knows the composition and properties of bread, the flour, salt, fermented dough, or yeast; a soapboiler will not be the less successful in his operations because he takes account of the character of the grease, the

pearlash, lime, and lye, because he knows the qualities that should be sought for in different substances, or has learned the signs by which they may be known. The simple inhabitant of a town or village knows himself that the science of his neighbor, the municipal counsellor, who possesses some knowledge of the principles, in virtue of which are determined the laws of the sanitary police, is truly beneficial to the community.

Surely, then, we may expect to gather in future much more important fruits from progress made by this opinion. Already sciences exercise a certain influence, to the profit of public prosperity (under restraint it is true, but increasing from day to day), over the system of arts and manufactures. Thanks to them, agriculture, as the illustrious founder of our academy has stated, will experience a revolution equally advantageous when it shall have recognized that the separation of agricultural colleges from other educational establishments of a general nature is an obstacle to intellectual progress; when it shall be admitted that the immediate cause of the general decadence and small success of these institutions is found to be the insufficient education, owing to the imperfect scientific instruction which is received in these schools, while they study there, at the same time, technical processes.

(Concluded in our next.)

### The Scottish Highlands.

A small volume has recently been published, on "*Management of Highland Landed Property*," by George G. Mackay, of Inverness. It consists mainly of a re-issue of several well written articles that appeared in the *Inverness Courier*. The writer displays an intimate acquaintance with the condition of landed property in the Highlands, and the hindrances to the development of its natural resources. A few extracts will be found generally interesting, particularly to those who hail from "the land of the mountain and the flood."—In reference to the recently much agitated questions of game and deer forests.

Mr. Mackay states—"We have said, and we confidently repeat, that farmers do not object to a fair stock of game, which it is conceded to be the undoubted right of every proprietor to preserve for his own benefit or enjoyment. Our forefathers could have no conception of what a modern game preserve consists. In those days game had merely a place in the equilibrium designed by the wisely ordained laws of nature, wherein the productiveness of every species is

uniformly in the inverse ratio to its powers of self-defence; and the stock of game was, so to speak, natural and moderate, holding the position designed for it by the decrees of an all-wise Providence—proportionate to its importance and value, but subservient to the interests and prosperity of other species, and above all those of man. By the hand of man, however, this equilibrium has been destroyed; and hence the evils complained of. May it not be deemed an excess of game when three or four hundred blackcocks are found by the farmer in his morning walk snugly set down on the top of his stooks. We have known instances in which, from their unceasing attentions in this way, a field that was estimated to yield 6 qrs. per acre only yielded two! Ay, we have seen portions of a field on which the stooks were so thoroughly lightened in this way, that the lucky owner was entirely saved from the labour of thrashing them! How shall we characterise the state of the game where, perhaps, in a large field of thoroughly enclosed turnips, a premium may be offered for the discovery of a single unbroken bulb; or where the farmer, in his homeward walk at dusk, is gratified with the sight of perhaps fifty hares in his promising braird? Is it to be wondered at that a rent payer should occasionally give vent to a little grumbling in such circumstances?"

If the farmers in the Highlands can solve the problem, What constitutes "a fair stock of game?" they are much wiser than their English brethren, who gave evidence before Mr. Bright's committee. Nothing is more condemnatory of game preservation than the above extract, which describes a state of matters not exceptional. The general system of the owners of lands in the Highlands is to obliterate all signs of ancient, as well as of advancing civilisation. Fashion is fostering a spirit of barbarism, the ultimate results of which appear to be that the Highlands of Scotland are ultimately to be rendered a comparative desert—the inhabitants and the domesticated animals being extirpated to make the country the domain of wild animals. Till the fact becomes more generally recognized that preservation of wild animals and high farming is incompatible, it is hopeless to expect the investment of capital, either in the reclamation of waste lands, or to lands already under the plough, so as to increase the agricultural products. Game and deer cannot be kept out of corn fields by any plan which has been adopted in the Highlands. With the extension of deer forests, the cultivator must recede, as well as the stock farmer. The onward march of the red deer is only to be stopped by the erection of a boundary fence more difficult to surmount than the Roman wall of Antoninus. [Mr. Mackay thus describes the result of the annually increasing extent of deer forests:—"Besides the loss of population, we incur the loss of a large quantity of the staple food of the people. Those exten-

sive tracts of land now under deer, formerly teemed with flocks and herds, which, after supplying the wants of the home population, were annually exported in great numbers to meet the demand of our manufacturing brethren in the south. To this extent, therefore, the nation becomes less supporting than it once was, and we must look elsewhere to meet the deficiency. The supplanters of these flocks—the deer—are, as is well known, no value in commercial point of view, so that there is no compensating supply in this way for the loss sustained. When a proprietor converts a large portion of his estate into a deer forest, instead of desiring to see increased traffic, and more of the stir and bustle of active business, as he would otherwise naturally do, he now seeks stagnation and stillness—he courts solitude and isolation, and aims at the reconversion of the country into the desolate hunting ground that it was a thousand years ago."

With such a system in operation, where are the chances of the improvement of the agricultural resources of the Highlands. Mr. Mackay states—"There are thousands, aye tens of thousands, of acres of waste ground throughout the Highlands, which, by the simple adoption of a judicious and enlightened policy, might be increased from twenty to forty fold in value in twenty-five years, at very little expense to the proprietor. This seems a startling statement; one apparently too good to be true. But is true, and we could adduce a hundred instances in proof of it. There are few farms, indeed, in the Highlands, to which there is not attached waste ground which might be profitably brought into cultivation. Yet there it remains, untouched and unprofitable in every respect, while the tenant would usually respond heartily to the offer of an advance by the proprietor for its reclamation. To the capitalist such improvement offers the highest possible inducement in the way of investment. The tenant will usually be found glad to pay 6 per cent. on the outlay; the proprietor has the best security for his money in the actual improvement of the soil, which he cannot possibly lose; so that such a safe and remunerative investment for money is rarely to be found. He reaps this interest for his money for the first nineteen years, and will derive from fifteen to twenty per cent. in perpetuity thereafter. And even where the proprietor has to borrow money for the purpose it will be seen that it is still his interest to improve. He can borrow from any of 'The Lands Improvements Companies,' at a certain rate of interest, to pay off principal and interest in twenty-five years. The tenant will be found willing to pay within, say one per cent. of the interest thus paid, and in many cases he will even pay the whole: so that the owner has his land converted from moor ground, worth perhaps a shilling an acre, without costing him anything but the trouble of negotiating the busi-

ness, or at the most at a cost to him of perhaps five pounds per acre."

And again—

"To what purpose are our millions of acres of improveable waste lands allowed to lie unproductive? It is said they are generally incapable of remunerative reclamation; and no doubt there are circumstances of soil, position, altitude, or climate, where such an assertion holds good. But we deny its applicability in general terms, so long as we see so many thousands of acres in our own locality now lying waste, which we know to be adapted to the raising of every species of cultivated crops. We can point out 20,000 acres of such land within twenty miles of Inverness, the so-called capital of the Highlands. Is this on account of an adverse climate? Are the waste lands not in the same climate with our present fruitful fields? Is it on account of their altitude? Have we not waving corn fields and a prosperous tenantry in the heights of Strathspey and Badenoch, in the brace of Urquhart, and in the very mountain gorges of the Monilia. And yet why are these more favoured lands not reclaimed? Not because they are not eminently adapted for cultivation—not because the people are unwilling to undertake the task (on the contrary, they are only too eager to do so,) but because the soil is not free. The entail laws so bind the hands of proprietors, that though they should have any disposition to improve, they cannot; neither can they treat with tenants on eligible terms; and, moreover they cannot sell their land to others who would improve them. The repeal of this law is one of the palpable modes by which it is in the power of the Legislature to advance, especially the Highlands of Scotland in which the evil effects of the law have been very severely felt. Tens of thousands of acres might thus pass into the hands of capitalists of every calibre. We might have our reclaimable moors sold out to industrious farmers in lots, as is now done in the forests of Canada. And if this were done, the grand climax of the emigrant's ambition—the goal to which he aspires, and which is the most attractive motive in inducing him to emigrate, viz., the possession of a piece of land of his own, on which he might labour and expend all his energies, with the satisfaction of leaving a certain patrimony to his family—this, we say, would be attainable at home as easily, and with as great a prospect of satisfaction, as it would be in Canada, or in any other country."

The author proceeds to state that in Canada the capital required to purchase and clear an acre of ground is equal to the fee simple of much of the reclaimable waste lands in Scotland. This may be correct in particular instances, but comparing the wild lands of the two countries, as a whole, for agricultural purposes, those of Canada are unquestionably very superior in point

of permanent money value and productiveness to the bleak and inhospitable elevations of the Scottish Highlands. No doubt but several of the wastes of the old country are susceptible of profitable improvement, but *in general* the same amount of capital and labour bestowed on the naturally rich level lands of Canada would, in the long run, be attended by much larger profits. The generally prosperous condition of our Scottish settlers is a sufficient proof of the correctness of this observation.

To effect an entire change in the present state of the Highlands, Mr. Mackay suggests several conditions, all more or less important aids for ultimate success. The abolition of the laws of Entail, increased facilities for the transfer of land, and the encouragement of railways by Government, partly by pecuniary aid, and also by ignoring and repudiating all exorbitant claims of damages by individual proprietors and corporate bodies, remarking that, "It is too bad that railway companies should in these days be under the necessity of buying up the good will of every small proprietor who may on the most trivial pretence threaten opposition. If Parliament ceased to listen to such claims, railway companies would not have to fear their opposition, and would be saved those heavy 'douceurs' which so cripple the resources and swallow up the rightful dividends of the undertakings. Parliament listens to these absurd claims, and to this fact we are further indebted for the expensive deviations from the simplest line which we so often see. If two lines are equally easy of construction, or nearly so, it is, of course, the duty of a railway company to select that which may be least offensive to the taste or prejudice of the proprietor through whose land the line passes. But it is surely unfair, on the other hand, that the necessities of the public should be kept in subordination to the caprice or whim of anybody who chooses to put himself in their way.

"In the Highlands especially, railways are a benefit to all classes, and to none so much as to the landowners through whose property the lines pass; so that the very mention of damages seems ridiculous, when the advantages are so great and so self evident. Such are the benefits resulting to the landed interest from railway communication, that instead of anticipating claims for damages, on the score of affecting the amenity of residences, or the revenue of ordinary road-trusts, and such like, we might rather expect the landholders to come forward, offering their lands, free of all charge, to any company who would undertake to supply them with such a boon as a railway. The grounds on which these claims for compensation are made are so utterly untenable that we only wonder that they have ever been given effect to.

"We heard not long ago of a proprietor exacting damages on account of having the amenity of his residence disturbed by the passing of a railway on the opposite side of a broad navigable river! The Inverness and Aberdeen Junction Railway, on equally good grounds, has had to pay heavily for anticipated damage to the trade and revenue of the Findhorn Bridge! And why has it not to compensate the steamboat companies along the coast for the presumed loss of traffic they will sustain? Why are not all the common carriers along the road compensated for their loss? Are there not vested interests at stake in these cases as well as in the other? It will be difficult to define the limit to which the principle, when admitted at all, is to be confined."

### Are the Long-Woolled Sheep of Tweedside Pure Leicester's?

By JOHN WILSON, EDINGTON MAINS, BERWICK-SHIRE.

Happening a short time ago to meet with an acquaintance who is a breeder of Leicester sheep, our conversation turned upon the discussions which had taken place last year, first at Kelso and afterwards in Edinburgh, upon the proposal which had been made to have in future two distinct classes of Leicester sheep at the Shows of the Highland Society. This naturally enough led to the question which I have placed at the top of the communication. As the gentleman referred to seemed much interested by some facts which I then adduced in support of the affirmative of this question, and expressed the opinion that they would be equally interesting to many others, I am induced to give them publicity.

All who take an interest in this question are aware that the proposal referred to above was made with the view of obviating the very great dissatisfaction which has again and again been produced by the way in which the premiums for Leicester sheep have been awarded at the Shows of the Highland and Agricultural Society of Scotland. The Directors of that Society, with the laudable motive of avoiding partiality, or even the appearance of it, have usually endeavoured to procure judges wholly unconnected with the district in which their Show is held, and have frequently obtained a portion of them from the midland counties of England. When the latter class of judges have been a majority, as at the last Show at Berwick, they have with perfect consistency awarded the prizes in every instance either to sheep from the south, or failing these, to such as approached the nearest to the English type. And so it has happened that the Border sheep, although constituting the vast majority in point of numbers, have been entirely ignored, and the prizes have been given to animals which, in the opinion of, near-

ly every spectator, were utterly inferior to all the better specimens of those which had been passed over. In such cases the third judge, being usually a north country breeder, has been placed in the disagreeable position of having to dissent from his colleagues at every decision and had better not have been there at all. At Perth last year the case was reversed: as two of the judges were Scotch and one Irish. The latter, having been used to sheep of the English type, could only look on and see his colleagues award the prizes quite contrary to his judgment. I do not see how the Directors could have come to any other decision than that which they adopted, viz., to deal with all Leicester sheep as constituting one breed. At the same time I am fully persuaded that their premiums will never be awarded in a way that will secure the confidence of the members of the Society, unless the decisions are made by men who at least recognize the genuineness of the Border sheep, and their eligibility to carry prizes when of sufficient merit. Now, it is well known that this is not the case with breeders from the midland counties of England, who for the most part, have no scruple in expressing the opinion that our Border sheep are not Leicesters at all. And our south country neighbours, while refusing to call our sheep *Leicesters*, have provided another name for them. In most of the reports of the recent show at Leeds, notice was taken of an experiment then in progress on the farm where the steam-ploughs were tried, for the purpose of testing the comparative merits of a number of different breeds of sheep, amongst which was enumerated the *Barnshire* breed. Again, in the prize report on the farming of Yorkshire, in the 22nd volume of the "Journal of the Royal Agricultural Society of England," p. 122, the author speaks more than once of the *Barnshire* breed of sheep. Now, I daresay, many persons, in reading these reports, must have been puzzled as to the locality of this *Barn* or *Barnshire*, and may have felt some curiosity to know what kind of sheep was referred to. The explanation is just this: A fair for the sale of draft-ewes has for a long time been held annually, in the month of September, near Wootter, in Northumberland, which, from the day in the calendar on which it takes place, is known as St. Ninian's, or, in northern dialect, St. Rignan's fair. The site of this fair lying in the part of Northumberland which in the olden time was called Bamboroughshire, the graziers and dealers from Yorkshire, by whom these ewes used to be bought, got into the way of calling their purchases "Bamboroughshire sheep," which for handiness was shortened into *Bampshire*, and has now as we have seen, got varied into *Barnshire* and *Barnshire*. The fair just referred to has now greatly declined from its former importance in consequence of the annual drafts of ewes from the innumerable flocks of Northumberland, Merse, and Teviotdale being

bought up at home, or at local markets, by dealers who convey them by rail to the great markets annually held at York, Harwood, &c. Forty years ago the sheep bred in the districts just referred to were exclusively Leicesters, and it was to these that the name Bampshire was first applied. About that date, however, many of our farmers began to try a cross betwixt Cheviot ewes and Leicester rams, and these two breeds were found to blend so readily, not only in a first cross, but also with a continued use of the pure Leicester ram and the cross-bred ewes for successive descents, and to produce so useful an animal, at once hardy, prolific, of good size, with great aptitude to fatten, and excellent quality both of wool and mutton, that this mixed breed rapidly superseded the pure Leicester, *except in the case of ram breeding flocks*. I may here notice that in the Border districts a pure Leicester is invariably called a *bred* sheep *par excellence*. Sheep of the first and second cross betwixt Leicester and Cheviot are in like manner *halfbred*, or two-parts *bred*, as the case may be; but when they are the produce of a pure Leicester ram and ewe of the mixed breed of three or four or more descents, I suspect that, when taken south, the old name of Bampshire is often applied indiscriminately to them as well as the pure Leicesters. The latter, as I have said, are now found only in the hands of regular ram breeders; but that their flocks are still comparatively numerous, may be inferred from the fact that, at the ram fair now annually held at Kelso in the month of September, from 1,600 to 2,000 shearing Leicester rams are presented for sale, and are most of them bred in the surrounding districts.

And now again for the question: Are these rams really pure Leicesters? They certainly differ much in appearance from the type of sheep now found in the midland counties of England. They are stronger in the bone, larger in frame, have white faces and legs, and are altogether of a more robust form than their modern English kindred. Are these diversities, then, due to crossing, or are they entirely owing to selection, and the influences of climate? Now, without claiming absolute purity for every flock, I do believe that those of the best breeders on the Borders can establish as direct and pure a descent from Bakewell's flock as any now to be found elsewhere. Let us inquire when, and by whom, the Leicester breed was first introduced to the Borders. It is well known that this was largely due to the Messrs. Culley, who in 1767, migrated from the county Durham to Tweedside, and brought with them excellent breeds of live stock, and in particular a flock of sheep of the pure Leicester, or *Dishley* breed, as they were then called. Mr. George Culley was the personal friend of Bakewell, and the author of a treatise on live stock, in which his description of the Dishley breed of sheep quite corroborates the opinion which it is my present object to

substantiate. Another person who took a leading part in introducing the new breed was the late Mr. Robert Thomson, of Lilburn, and afterwards of Chillingham Barns in Northumberland, who in his youth resided for some time with Bakewell as his pupil, and whose flock, long known as one of the best on the Borders, was bred directly from Bakewell's. I cannot, of course, speak of the flocks of the breeders now named from personal observation, as they had all either died or retired from business by the time I began; but I inherited from my father a flock of Leicesters which had been bred chiefly from their flocks, and I have thus been familiar from my earliest years with the style of sheep which they introduced. About thirty-five years ago, and for many subsequent years, there existed a small flock of Leicesters, the property of Mr. Luke Scott, formerly tenant of Easington Grange, near Belford, which I knew well, and which, in several respects, may be said to have been unique. Mr. Scott, although a steady and upright man, had not prospered in business. From ever I knew him he had no farm of his own, and his little flock, numbering some twenty ewes and their produce, to which he clung with fond affection and almost desperate tenacity, was boarded out, sometimes in one place and sometimes in another, often exposed to great straits, and never enjoying anything like fair treatment. He has often told me that the foundation of this flock was laid by the purchase of a few shearing ewes from a Mr. Yellowly, then in good repute as a breeder of pure Leicesters. As long as Mr. Robert Thomson continued a breeder, Mr. Scott had used only rams, or their progeny, of his own breeding; and for the 20 or 25 years which elapsed betwixt Mr. Robert Thomson's retirement from business and the final breaking up of Mr. Scott's little flock, the latter was maintained entirely by the use of his own rams. So jealously did this exclusive old man watch over the purity of his idolised little flock, that I recollect of his telling me how a favourite ewe had made her escape from the enclosure in which she was confined, and had got access to a ram of a neighbouring flock. Most persons would have thought it enough in such circumstances to have sold or destroyed the progeny of this *mesalliance*; but so irremediably did the old man consider his ewe to have been contaminated, that favourite as she was, he caused her instantly to be slaughtered. Mr. Scott let out on hire as many of his rams as he could, but never sold either male or female except to be slaughtered. And what, then, were the characteristics of this interesting little flock, separated from Bakewell's by but one intermediate link? Their faces and legs were invariably white—as much so as any Cheviot's. Their wool formed a close-set, compact fleece, inclining to coarseness in the breech, and often scanty, or altogether awanting, on the belly. The rams carried their heads well up, being

strong and full in the neck-vein, and remarkably wide in the chest. They were particularly clean in the legs, and seldom suffered from foot-lameness. They were vigorous and active, and in token of this were pugnacious to a fault, being more troublesome in this respect than the rams of any breed of sheep I have ever had to do with. Owing to their own purity of breeding they possessed in a remarkable degree the capacity of imparting their own characteristics to every flock into which they were introduced. Mr. Scott never had many of our ram breeders as direct customers, as they objected to the comparative want of size of his sheep; but I have the best means of knowing that most of them freely availed themselves of his blood by hiring rams from those who did deal with him directly. So much was this the case, that there is probably no Leicester flock on the borders, of any considerable reputation, that has not this blood largely in it. The comparative want of size, to which I have just referred, always appeared to me to be less an inherent quality than the inevitable consequence of long continued hardships. I have thus shown that we got the genuine Bakewell blood to begin with, and that, in one instance at least, it was preserved amongst us, until a very recent date, in a degree of purity not equalled anywhere else, unless, perhaps, in Mr. Valentine's flock. Let me not, however, be misunderstood as if I wished to convey the impression that the breeders whom I have named were the only persons on Tweedside who were direct introducers of Bakewell's blood. There were many others whom I cannot enumerate. I may mention, however as being Berwickshire breeders, the late William Robertson, Esq., of Ladykirk, and his tenant and intimate friend the late James Thomson, Bogend, who both, down to a yet recent date, went annually to Leicestershire and hired rams from the best flocks there. Mr. Robertson's flock of about eight hundred ewes dispersed in consequence of his death about 1830, and is still represented in the district. Mr. Thomson's remains intact in the hands of his grandson at Mungo's walls, and is still used as a ram-breeding flock.

Much as the Leicester sheep of the south and of the Borders now differ from each other, I believe that both can equally claim and prove direct descent from Bakewell's flock. Diversity of climate and general treatment, and diversity of taste in the breeders, have for a prolonged period been at work to produce the change; and these are influences potent enough to account for all the change which has actually taken place, although both started with like materials. Bakewell, we know, had just the common long-woolled sheep of his day to work upon; and he by skill and perseverance, so changed them as to originate what has ever since been recognised as a distinct breed. The materials which proved so plastic in his skilful hands are still as susceptible of modi-

fication as ever they were. As a matter of fact, not our sheep only, but all our domesticated animals are constantly varying. It is not only the flocks of widely remote districts that exhibit this variation; it can be seen any day, and everywhere, by comparing together any given number of flocks in the same neighbourhood, each of which will be found to have well-marked family features, by which it can be readily discriminated from the others.

The point of real practical importance is, that everywhere the Leicester breed retains the qualities which from the first made it so valuable. It is true that it is not now put to the same use as formerly. It no longer yields directly our staple supplies of butcher meat; but crosses betwixt it and the Downs in the south, and betwixt it and the Cheviots and Blackfaces in the north, now constitute the main supplies to all our markets.

January, 1862.

Before publishing the foregoing statements, it occurred to me that it would be well to submit them to two gentlemen who I knew to be well qualified to judge of their accuracy—viz., John Gray, Esq., of Dilston, and Thomas Scott, Esq., late of Beal. It is with peculiar gratification that I append the following excerpts from the letters with which they favoured me on returning my manuscript. Mr. Gray says:—

"I have been favoured by reading your paper on the genuineness of the Border Leicester, and, as I am going from home in the morning, I give you, at a late hour, a hasty line, to say how entirely my opinion concurs with your own as to the still existing purity of the *ram-breeding* flocks in the Border countries \* \*

I quite agree with all you say of George Culley and Robert Thomson, first at Lilburn (when the first sale of auction in the North of a pure-bred Bakewell flock took place) and next at Chillingham Barns, where he had annual lettings, at which I took rams, and learned my first lessons in the symmetry and quality of the pure Leicester. I well remember also his sale of all his flock there in May, 1814, when I was, though young, one of the judges, and presided at the dinner in a barn full and overflowing. I regularly attended the public lettings at Mr. Culley's too, and hired rams, very often. Those two flocks were certainly pure Leicester, if Bakewell's were pure—and we can go no farther back. But then there were two families in Bakewell's flock, distinguished as *blue caps* and *red legs*, which came out at times in their descendants. You must have seen and known a kind of Leicester with blue faces, generally bare on the scalp, and red when lambed, and when mature, easily broken by flies, on which account they were not favourites with the shepherds. They were good feeders, but light of wool. The red or brown legs were a hardier tribe, and good in carcass also. I remember one of the

best rams I ever had being one of that kind—hired at sixty guineas from Mr. Thomson (descended from Bakewell's). That class of sheep was then used and approved by Messrs. Jobson of Turvilaws, Vardy of Fenton, Smith of Norham, Smith of Hayfarm, &c., &c., and continued in those families until within the last twenty years. So long as a sheep-flock was kept at Millfield Hill no alloy or impure cross was ever admitted; but yet the character of the sheep was rather altered to suit the taste of those who hired my rams. The original breed was from Thomson's and Culley's, my father having bought gimmer's from Thomson at an early time. By way of change, I hired sheep from Burgess, and then I had three for two years from Lord Althorp, got by Buckley's best ram, called Big B., which his Lordship had for two seasons. Those sheep were perfect as to shape and quality, but on a low leg, with a round full carcass, fulfilling Bakewell's toast, 'small in size, and great in value.' If I had fed all my sheep to the end for the fat market none could have paid better than those for early maturity and the amount of mutton produced per acre, although not in large frames; but in that neighbourhood all the ewes are sold for breeding another year in Yorkshire, and the buyers like them to stand on a higher leg, and make a bigger, if not better, show in the pens of York and Wakefield: and so also with dimmons sold in the autumn to be fed in the South. Chiefly on this account, and partly because more farmers reckon more by the price they get *per head* than by the *aggregate amount* of mutton and wool in sheep of smaller size, I was induced to follow the public taste and to cultivate a large-sized sheep, but without sacrificing purity of blood. The taste prevailed, I think, pretty generally on the Borders, and has wrought, together with the effects of climate, in changing considerably the look and character of the Leicester sheep in those parts from that of the original Leicester sheep of that county and Warwickshire, &c. I have seen most marked changes produced by local circumstances on Leicester sheep. I once bought some shearling rams in this county for a friend in Ireland. I saw the sheep in Queen's County three years after and could hardly believe them to be the same, so coarse were they in wool, and so changed in character. \* \* \* You are quite right as to the origin of the name Barn, or Barnshire sheep. I remember old Green, a large buyer from Yorkshire in the beginning of this century, who always used that term in speaking of the draft ewes he bought in Bam-boroughshire and Glendale. Your account of old Luke Scott's little flock is very curious and strictly true. I knew him at Easington, and used to meet him at the shows at Chillingham Barns. The last of his diminished flock was at a poor place by the road south of Wooler, called Plea Place, where his son once asked me to stop and look at the sheep which he thought

combined in perfection what I had described at some meeting as the true qualities of the pure Leicester. \* \* \*. The flocks of Ladykirk and Bogend were purely Leicester to the end, if Leicestershire rams hired at good prices were pure. I had the privilege of being well acquainted with both Mr. Robertson and Mr. Thomson, who for many years used to have their horses rested with me in passing Millfield Hill, so that I might have a view of the rams. But even in these there was as great a difference between those from Stone, Stabbins, Burgess, and Buckley, as now exists between those of Nottinghamshire and Northumberland."

Mr. Scott says :—

"Your remarks are in perfect accordance with my recollection of the conversation which I have heard upon the subject by my seniors. There is nothing I could add of my knowledge to the very full history you have given of the breed in this district."—*Journal of Agriculture*.

### Sewage Irrigation.

BY CUTHBERT W. JOHNSON, ESQ., F.R.S

The use of the sewage of towns in irrigating grass lands is now exciting that attention which its public importance demands. A royal commission and a Committee of the House of Commons have been appointed, with full power to institute experiments, and to examine witnesses. That Parliamentary Committee has recently published its first report, and from that we may readily learn how correct are the general conclusions of the farmer, and how absurd have been the reasons of those who have systematically decried the importance of these fertilizing streams.

It may be very true that the experiments given in evidence before the Committee were not always made with the requisite care; that the amount of sewage applied was often far too small, and at too distant intervals; but still, after allowing every necessary drawback, there yet remains in that report a very considerable amount of facts well worthy of my readers careful consideration.

In this inquiry the amount of sewage needed to produce the most profitable result is indeed the primary question. Now, in the great sewage irrigation operations so long successfully carried on at Milan, and at Edinburgh, the quantity annually applied per acre appears to be about 5,000 tons. In Northern Italy, where five or six crops of grass are annually produced by the irrigation of the meadows near Milan, with the river water, into which the city sewage is discharged, an annual charge is made for the use of the water. It appears from the report of Mr. Smith upon Italian Irrigation, that the price paid annually for the irrigation water is.... 5s. 9d.

That during the summer season the meadows are watered..... 18 times.  
That the weight of water applied per acre each time is about..... 230 tons.  
That the annual produce per acre of

grass is about.....,..... 224 cwt.  
That this is about the most beneficial amount of liquid to apply per acre accords with what I had long since occasion to remark. It was after examining the amount of water required to saturate thirteen kinds of soil that I was led to conclude that if we calculate the mean amount of water in these thirteen varieties of saturated soils to be equal to 42lbs. per cubic foot of earth, or 378lbs. per square yard of soil a foot deep, then  $378 \times 4840$  (the number of square yards in an acre) gives 1,829,520lbs. of water needed to saturate an acre of perfectly dry land to the depth of one foot, or about 816 tons. If we suppose that the saturation of the soil need only extend to a depth of nine inches, then about 543 tons of water would be sufficient; if a depth of only six inches, then 408 tons; and if only a depth of four inches, then 273 tons would suffice. It appears from the report of Dr. J. Stark, that the celebrated Craigentinny Meads, near Edinburgh, are annually irrigated by the city sewage about eighteen times. For instance, a certain plot was watered in its turn, May 3 and 14, June 3 and 20, Aug. 15 and 31, Oct. 8 and 29, Nov. 24, Dec. 31; in 1845, Jan 30, Feb. 18, March 5 and 22, April 2 and 13. Now, if we calculate that, on an average of months, 250 tons of irrigation water would suffice to saturate the soil (always partially and sometimes thoroughly previously moistened), then it would require 4,700 tons of water to give these eighteen irrigations to an acre of land. I deem the quantities I have stated as likely to be an average amount of sewage fluid required for the irrigation of an acre of grass land to be nearly correct. In the report of Mr. George Buchanan, engineer for the irrigated meads of Craigentinny, near Edinburgh, he states the quantity of water necessary per acre to be equal to a stream of sewer fluid of  $3\frac{1}{2}$  cubic feet per minute for 12 days of 10 hours each, or about 650 tons. It will be remarked, however, that the sewage fluid in this case had to sustain the soakage, leakage, and evaporation during thirteen days of the month of May. This slow irrigation is far from being the most economical mode of applying the sewage—the more rapid and copious application being to be preferred, as affording little time for the soakage of the substratum, and the leakage from the soil into the drains, and evaporation from the surface. Mr. Buchanan also adds, "In some parts the soil consists of very stiff clay, resting on a similar substratum, and other parts of a red sand, and the sand requires nearly twice as much water for saturation as the clay." We see, then, that the amount stated by Mr. Buchanan of about 700 tons per acre having been

used at Edinburgh upon a mead, and subject to many deductions from its saturating power, is not very widely different from the average amount of about 800 tons required, according to Professor Schubler, to saturate the same extent of nearly chemically dry, earths. Then, again, by avoiding the soakage and drainage waste of twelve days, and taking the average rate of moderately retentive soils, a very material saving would doubtless be accomplished; and, moreover, by raising the sewage fluid to the contemplated elevations, it would be available, as at Edinburgh, for the use of the irrigation a second time. The use of sewage waters a second time in irrigation, is an old-established practice in Italy. In the celebrated meads of the neighborhood of Milan, "the water of the draining channel," says Count Arrivabene, "is collected into another channel, which conducts it to irrigate another meadow in a similar manner. Upon the whole, therefore, I am inclined to think that the calculated quantity of 4700 tons per acre annually is a tolerable approximation to the truth."

In the experiments instituted at Rugby by the members of the Royal Commission the amount applied per acre has been in these experiments 3,000 tons, 6,000 tons, and 9,000 tons per annum. In these trials two material objects were hoped to be attained, viz.—1. To ascertain the amount of increase of produce from the application of different proportions of sewage to grass. 2. The most beneficial mode of using the grass produced, whether for milch cows or for fattening stock, given either by itself or with other food. These experiments were attended with very valuable results, although they were conducted under considerable difficulties, and the amount of sewage available was considerably less than was intended. The following results are given in the words and figures of the report:—

Two fields were employed in these experiments, viz., one of five acres, the produce of which was intended to be devoted to the feeding of oxen, to which the sewage was in these trials first applied on the 6th March, 1860; and one field of ten acres, to which the sewage was not conducted until the 1st of April. The chief results obtained were, that in the five-acre field the produce of grass obtained from four plots was as follows:—

|                                                                                        | Tons. Cwt. |    |
|----------------------------------------------------------------------------------------|------------|----|
| 1. Plot not dressed with sewage produced in two cuttings, of green grass per acre..... | 9          | 53 |
| 2. Plot dressed with 3000 tons of sewage per acre, in four cuttings                    | 14         | 16 |
| 3. Plot with 6,000 tons, in four cuttings.....                                         | 27         | 1  |
| 4. Plot with 9,000 tons, in four cuttings.....                                         | 32         | 17 |
| In half of the ten-acre field—                                                         | Tons. Cwt. |    |

|                                                                     |    |    |
|---------------------------------------------------------------------|----|----|
| 1. Plot, soil undressed, produced in two cuttings.....              | 8  | 18 |
| 2. Plot dressed with 3000 tons per acre produced in four cuttings.. | 15 | 16 |
| 3. Plot dressed with 6,000 tons in four cuttings produced.....      | 22 | 15 |
| 4. Plot dressed with 9,000 tons, in four cuttings.....              | 26 | 13 |

So that the increase of grass from the application of every 1,000 tons of sewage was, on an average, between three or four tons per acre.

In the experiment made with the grass in fattening cattle ten Hereford oxen were employed. They consumed, during sixteen weeks, per head daily 105½ lbs of the grass; so that the grass of each acre was sufficient to keep an ox, from

|                                         | Weeks. |
|-----------------------------------------|--------|
| The soil simple.....                    | 32.9   |
| The soil with 3,000 tons of sewage..... | 45.    |
| The soil with 6000 tons.....            | 82.1   |
| The soil with 9000 tons.....            | 99.7   |

The value of the increase of the oxen in live weight per acre, at 4d. per lb., was as follows:

|                            | £ | s. | d. |
|----------------------------|---|----|----|
| Grass from soil simple.... | 1 | 8  | 11 |
| Ditto 3,000 tons.....      | 2 | 4  | 3  |
| Ditto 6000 tons....        | 4 | 0  | 9  |
| Ditto 9000 tons....        | 4 | 18 | 0  |

So that the value of the live weight from the increased produce of 1,000 tons of sewage was, from the grass land dressed with

|                          | s. | d. |
|--------------------------|----|----|
| 3,000 tons per acre..... | 8  | 2  |
| 6,000 tons ditto .....   | 10 | 10 |
| 9,000 tons ditto .....   | 10 | 3  |

In the trials with milch cows, twelve were selected, and fed upon grass alone for sixteen weeks. Two cows were fed on the grass from Plot 1, which had not any sewage, and ten cows with the grass from the sewaged plots 2, 3, and 4.

|                                                                                                     |           |
|-----------------------------------------------------------------------------------------------------|-----------|
| They consumed daily per head of grass from the plot without sewage....                              | 138.7lbs. |
| From the sewaged plots.....                                                                         | 125.9lbs. |
| The average daily yield of milk per head from the cows fed with grass grown without sewage was..... | 25.05lbs. |
| From those fed with the sewaged grass                                                               | 20.53lbs. |
|                                                                                                     | Weeks.    |

|                                                                                    |          |
|------------------------------------------------------------------------------------|----------|
| The number of weeks the grass grown without sewage would keep a cow per acre ..... | 20.6     |
| The grass from the land which had 3000 tons of sewage per acre....                 | 40.3     |
| From that which had 6,000 tons per acre                                            | 57.9     |
| From that which had 9,000 tons per acre                                            | 67.9     |
| The gallons of milk each acre would yield was from                                 | Gallons. |
| The grass without sewage.....                                                      | 350.7    |
| The acre with 3,000 tons of sewage                                                 | 562.3    |
| The acre with 6,000 tons.....                                                      | 807.8    |
| The acre with 9,000 tons.....                                                      | 947.4    |

The value of the produce of the milk from each acre was,

|                                                      | £  | s. | d. |
|------------------------------------------------------|----|----|----|
| From grass without sewage, at 1s. 6d per gallon..... | 11 | 13 | 10 |
| The 3,000 tons of sewage grass....                   | 18 | 14 | 10 |
| The 6,000 tons of sewage grass....                   | 26 | 18 | 7  |
| The 9,000 tons of sewage grass....                   | 31 | 11 | 7  |

The increased value of the milk from the application of each 1,000 tons of sewage to the grass was therefore about £4 12s.

As some doubt had been entertained as to the comparative value of the milk from the cows fed with the grass produced with and without sewage, the composition of 100 parts of the milk from the cows fed on the grass from the unsewaged and the sewaged grass was ascertained by Professor Way. He analyzed nine samples of each. The mean of these was as follows :

|                        | Unsewaged. | Sewaged. |
|------------------------|------------|----------|
| Casein, or cheese..... | 3.246      | 3.241    |

100 100

From these analyses we may conclude that the composition of the milk is but slightly influenced by feeding the cows with the sewage-irrigated grass. The results of the analyses of the sewage of a country town like Rugby will not be without interest to my readers. Twenty-six samples of this sewage when analyzed gave the following mean result per gallon:

|                                   | Grains |
|-----------------------------------|--------|
| Organic matter in solution.....   | 10.35  |
| “ in suspension.....              | 15.22  |
| Inorganic matter in solution..... | 37.22  |
| “ in suspension.....              | 15.25  |
| Ammonia in solution.....          | 5.27   |
| “ in suspension.....              | 1.50   |
| Potass.....                       | 1.04   |
| Phosphoric acid.....              | 0.93   |

So that each 1,000 tons of such sewage convey on to the land, in solution and in suspension—

|                       | lbs.  |
|-----------------------|-------|
| Organic matter.....   | 818   |
| Inorganic matter..... | 1,679 |
| Ammonia.....          | 217   |
| Potass.....           | 33    |
| Phosphoric acid.....  | 30    |

In almost all the investigations into the agricultural value of sewage which have hitherto been made too little attention has been paid to the value of the mere water of the liquid. In the experiments carried on at Rugby, the water bestowed upon the grass in the sewage was equal to a rainfall of about 30, 60, and 90 inches per annum. Now, if this large amount of liquid had been only rain water, the increased produce of grass would have been very considerable.

The weight of grass produced in the east of England moistened by an annual rainfall of 20 inches, is, we all know, very inferior to that yielded by similar soils on the western part of the island supplied with a rainfall of 40 inches, and vastly inferior to the produce of the meads of the chalk formation annually watered with at least 50 inches of the bright waters as pure as when they issue from the chalk.

Then, again, it is not merely the amount of the organic and other matters conveyed into the grass which should be valued, but their thorough diffusion in the soil, and the state of solution in which they come in contact with the roots of the plant, is also a very material element in the case. The amount of guano which the Peruvian cultivators sprinkle over their fields is said to be very small in amount, but then they always irrigate the land as soon as the guano is spread. Every English farmer is aware how much more valuable is the effect of this manure, when he employs it in heavy rains; for its valuable portions are then dissolved in the rain water, and diffused through the soil. Irrigating with sewage accomplishes a similar object with far more certainty.

In the case then of lands so situated that the sewage can be conducted on to them by its own gravity, the importance of its employment in irrigation need hardly be advocated. In those many situations where the outfall of town sewers is too low for the sewage to be thus conveyed on to the land, recourse must be had to the steam engine and the pump. Now, supposing it is necessary to raise such a considerable amount of sewage from a lower level to the surface of the soil, then the following observations as to the consumption of fuel required to raise water to various heights may be useful: for these I am indebted to Messrs. Ransome and Sims, of Ipswich. The greatest effect in pumping water is found in the Cornish pumping engines: now, the average of these fire engines, reported in June, 1851 (being twenty-five engines) is 62,000,000 lbs. of water raised one foot high by the consumption of 1 cwt. of coals. These engines are very large, the steam is used expansively, and condensed, and every appliance adapted to economise fuel. Probably we shall not be far from an average, if we estimate that the small engines used for agricultural purposes will not perform more than one fourth of this “duty,” or say, 16,000,000 lbs. of water raised one foot high by the use of 1 cwt. of coals. It must be understood that the same weight of coal will lift half the water to twice the height, or one-fourth the water to four times the height, and so on. Now, supposing that we have to lift the water from a stream to the portion of a field which is ten feet above the level of the river, then 1 cwt. of coal will lift to that height one-tenth of 16,000,000 lbs. of water, or 1,600,000 lbs. A gallon of water weighs 10 lbs., and

therefore 160,000 gallons will be lifted, or, as 224 gallons weigh a ton, 714 tons of water may be raised 10 feet with the consumption of only 1 cwt. of coal: and this is almost exactly equal to an inch in depth over seven acres, or an average fortnight's rain in the southern and midland counties of England.

The subjoined table gives the gallons of water which may be lifted to various heights by the consumption of 112 lbs. of coal; the pumping apparatus being good, and adapted to the power of the engine, the calculation being based upon the preceding datum of 1,600,000 lbs.

|                                         | Gallons.  |
|-----------------------------------------|-----------|
| One cwt. of coal then will raise 1 foot | 1,600,000 |
| " " 2 feet                              | 800,000   |
| " " 3 feet                              | 533,000   |
| " " 4 feet                              | 400,000   |

| " " 12 feet                             | 133,333   |
| " " 13 feet                             | 123,076   |
| " " 14 feet                             | 114,444   |
| " " 15 feet                             | 106,666   |
| " " 16 feet                             | 100,000   |

The use of sewage in irrigation, as I long since ventured to predict, will, there is little doubt, be chiefly confined to grass lands. Of this opinion is Professor Voelcker, who on this subject recently addressed the members of the Royal Agricultural Society. In most of the conclusions to which he arrives I heartily concur, and in none more so than when in the course of his able lecture he had occasion to inquire why it is that grass is especially benefited by the sewage of towns. It is so, he added, because it is a quick-growing crop, which allows us to apply a fresh quantity of fertilising matter as soon as a given quantity is exhausted. We can repeatedly manure the grass crop, but we cannot the cereal crop. We should never get our wheat ripened if, after it has passed through its grassy condition, and arrived to some extent at maturity—we should never get the grain formed, if we were to apply sewage to it. Neither can we well apply sewage to market produce; at least not on most soils; for sewage has a tendency to close up the pores of the soil, and to enrust it, which is a great practical inconvenience. We should also remember that we must dispose of the sewage of a town at all times of the year, and that we must therefore apply it in very large quantities at a time. Now, to grass lands we can apply very large quantities, because grasses grow very rapidly, and enable us to give a fresh dressing or a large dose of manure.

Upon the importance of these scientific researches I need hardly remark. The intelligent

readers of this widely circulating magazine are well aware that in working out the great problem as to the best disposal of the sewage of towns, two noble objects are to be attained—1st, the improvement of the public health; and 2ndly, the increased fertility of our cultivated soils. The experiments to which I have drawn the reader's attention will materially tend to promote these great objects, for they will enable the cultivator to proceed on safer, because still better understood ground. Of one conclusion I am quite certain—that if the course of the streams of sewage, now commonly worse than wasted, are only so altered as to be available to the skilful agriculturists of our country, they will need no arguments to induce them to turn those now noxious streams to a nationally important purpose.—*Farmer's Magazine.*

### Sir Edward Bulwer Lytton on Agriculture.

Sir Edward Bulwer Lytton was present at the dinner of the Herts Agricultural Association, and responded to the toast of the county members. The right hon. baronet adverted to the remarkable progress which had been made in farming, and pointed out the great distinction between fancy and practical husbandry. "I remember," he remarked, "an amusing anecdote of a certain nobleman, who was a great farmer, and also a great epicure. He kept a famous prize ox; he kept also a famous French cook. Once on a time he invited some distinguished friends to accompany him to his country seat, and sent the cook on a few days before to prepare for the entertainment. As soon as he arrived he was impatient to show his friends his prize ox, and carried them off to the farm yard. When he came to the stall in which the ox was kept, lo, and behold, the ox was gone! He called to the herdsman, 'Why, where is my prize ox?' 'Please your lordship,' said the man, 'the French cook came to look at him two days ago, and admired him greatly; since then the ox has disappeared.' Much astonished, my lord hastened to seek an explanation of the cook, and found him very busy in his private room near the kitchen. 'What is this story about my prize ox? What have you done with my Durham ox?' 'Ah, my lord,' said the cook, 'I have him here safe and sound;' and so saying, he opened the cupboard, and on one of the shelves showed his lordship a small jar. Pointing to the jar, he said, with gauc complacency, 'There! you see, my lord, he was rather too tough for a roast, but I have stewed him down into a famous sauce!' Now, I am sometimes reminded of that anecdote when some gentleman fancy farmer carries me over his model farm. One sees much to admire in expensive nick-nacks and clever inventions, but when one delicately inquires into the state of the balance sheet the admiration cools. And many a fancy farmer who wants to look at his net profit as my

lord wanted to look at his prize ox, may be astonished to find how many pounds of solid substance may be scientifically stewed down into a very small jar of sauce." He enlarged upon the advantages of agricultural societies both to the farmer and labourer, and then proceeded to speak of the importance of utilising the sewage of towns to agricultural purposes:—"I remember, when I held the Colonial seal, the trouble and toil it cost me to secure from some distant islands a scanty supply of guano, while all the time, close at hand, a few of the London sewers were every year casting away into the Thames more than half a million's worth of a manure considerably more valuable for the general purposes of agriculture than that guano which ships were fitted out to bring home, in order that it might be retailed at a price which rather fits it for the phials of an apothecary than the fields of a farmer. I said half a million's worth of money was thus thrown away, but that is a very low estimate of the real waste. In Flanders, for instance, where I have been lately, the value of sewage is calculated according to the numeral population, especially in towns. It is there calculated at £1 7s. a head yearly. In Belgium it is calculated at a still higher rate. So that, if the population of London be taken at 2,000,000 a means of increasing the productive wealth of the country, which, according to the estimate of Flanders would be worth £2,700,000, is exclusively devoted to poison the waters of the Thames, and administer gratuitous disease to her Majesty's metropolitan subjects. If we may condescend to take lessons from barbarians, the Chinese may, in this respect, be our teachers. The rapidity with which the Chinese bring almost any soil into cultivation, and, when brought into cultivation, the enormous crops which they contrive to take from mere handfuls of land, have been the wonder and admiration of travellers. But the great secret of the Chinese is in the utilisation of sewage. The proverbial fertility of Belgium is owing, in much, to the same cause. But it is not only the sewage of London which is wasted, but that of all our own rural towns; although in them there appears a more impatient desire to remedy acknowledged abuses than seems to be the characteristic of city aldermen and metropolitan boards. When I consider how many populous towns there are in this country, I heartily wish we could send among them a few enlightened Chinese engineers to devise the best practical means by which our town-folk might be enriched by the manure they could sell, and our farmers enriched by the manure they could buy. But, in the meanwhile, until some such scheme is devised and agreed to, we must fall back on our old friend the farm-yard dunghill, assisted, indeed, by various chemical manufactures, but never to such a degree as to supply its place. Professor Liebig is, no doubt, right in considering the chief art of productive husbandry to consist in the skilful application of

manure. David Hume tells us, in one of his essays, that all the vast apparatus of our government has ultimately no other object or purpose than the distribution of justice to the soil—in other words, the application of that manure which gives back to the soil the nutriment we take from it, or supplies the nourishing properties which nature had neglected to bestow. Eight hundred years ago there was a very learned dispute whether or not the earth was an animal. We have now discovered that the earth is so far an animal that it requires to be fed and will not bear to be starved. A remarkable instance of this truth is mentioned by a celebrated agricultural authority, in some of the Southern States of America—such as Maryland and Virginia. In these States there were large districts of some of the most fertile land in the world, the crops they yielded were prodigious; but, unluckily the cultivators neglected the manure; they took from the land the alkalies and salts, which they did not replace, and these districts had now become so hopelessly sterile that they have been altogether abandoned as a desert. Now, if it be true that the fertility of the soil thus depends on the nourishment we give to it, there can be no stronger argument for the perfect confidence which ought to exist between landlord and tenant, so that the enterprise of the former may not be checked by any reasonable fear that he should not have his fair share of the profits in whatever he permanently adds to the fertility of the soil. For, on the one hand, the farmer cannot, on the long run, enrich himself unless he does justice to the land, and, on the other hand, the landlord cannot, on the long run, benefit his estate unless he does justice to the cultivator. The healthiest condition of productive industry, whether in farming or anything else, must be that which attracts to its cultivation capital and intelligence by the rational calculation of adequate returns. Now, when I look forward I can see many causes at work to give assurance to investments in agriculture, whether for the owner or the occupier. The increase of population, the certainty that new towns will spring up in the neighbourhood of railway stations, the tendency to building even in the quietest old rural towns if sufficiently near to railway communication—above all, the vast and progressive influx of gold, all must serve every year more and more to increase the value of land, widen the demand for its produce, and maintain the standard of its remunerative prices."

### Lake Superior Region.

The following facts as stated in a recent article of the *Globe*, are full of hope and interest in relation to an extensive and yet unsettled portion of British territory. The great Northwest when surveyed and opened up to settlers

will afford a profitable and unbounded field to agricultural, as well as mining enterprise.

"We have received from Sault Ste. Marie some very satisfactory and pleasing proofs of the capacity of the neighboring region to sustain the human family. They came to us in the shape of specimens of fall and spring wheat, oats, peas, beans, barley, potatoes, beets, turnips, carrots, cabbage and parsnips, grown in and around the village of Sault Ste. Marie, partly by Mr. Pind, the postmaster, the rest by neighboring settlers. As a matter of course, it has been known that root crops could be grown throughout the entire Lake Superior region, but such specimens of roots as we have obtained are not often exceeded in the western peninsula of Upper Canada. The potatoes would have bid high for the first prize at the late show in Toronto had they been exhibited. Spring wheat, oats, peas and barley, it was also known, could be grown very far to the north, but it was not believed until the experiment was tried, that fall wheat of the finest quality could be produced in the latitude of Sault Ste Marie. We think this fact of the greatest importance. There has always been an impression prevalent that the country lying between the Georgian Bay and the head waters of Lake Superior was not as fit for settlement as other parts of Upper Canada. It was thought to lie too far north, have too severe a climate. The same prejudice prevailed against the northern part of the western peninsula. It is only a few years ago since it was believed the climate of the counties of Simcoe and Grey were too cold to permit of the lands affording a full return to the Agriculturist. The fine settlements in the townships on the shores of the Nottawasaga bay alone would have caused this prejudice to explode, even without the testimony of the magnificent range of country stretching west to the Saugeen. We fancy there will soon be a similar dis-allusion in reference to the Lakes Huron and Superior County. Certainly there will if this sample of fall wheat is a fair specimen of what can be grown throughout that region. People enquiring for a place of settlement will not be content to take hearsay evidence, and will make personal examination and act on their own judgment.

"It is not upon agriculture alone that this region will depend for its future progress. It has splendid timber, rich fisheries and minerals, the extent and value of which are known to be great, although, from the folly and lack of knowledge of the early explorers, but little has yet been done to make them practically available. It is a well watered country, inviting to the lumberer and the manufacturer, and there are many points along its shores where large and prosperous towns will unquestionably arise. Look, for example, at the position of Sault Ste Marie, situated on the highway which will pass the gigantic traffic of both sides of Lake Superi-

or and of the North West. It has rich minerals within a few miles, abundant water-power easily made available, and a fertile tract of country behind it. Land within a few miles of this place can be had from the Government for 70 cents an acre, and at a greater distance for 20 cents. The demand for agricultural produce is already good.

"Throughout this entire region there are many things to attract the man in search of a new home, and we trust that explorers will be numerous during the coming spring. Not only is it of great importance to Canada that this region should be itself opened up; its settlement will have a most important effect in encouraging movements still further to the westward. It is the first stepping stone to the Saskatchewan, Fort William is the second, Fort Garry is the third."

### On the Commercial Value of Artificial Manures.

BY DR. AUGUSTUS VOELCKER.

Having in my capacity of consulting chemist to the Royal Agricultural Society, numerous samples of all kinds of artificial manures annually submitted to me for examination and opinion, and having, moreover, made myself practically acquainted with the manufacture of artificial manures, and attentively followed its rise and progress, I believe that I am in a position to say, without hesitation, that the true money value of a manure cannot always be calculated with anything like precision by mere reference to an analysis and certain valuation tables. I feel inclined to go a step further, and maintain that, at the present time, such mere rule-of-three calculations frequently convey wrong impressions of the value of certain manures, and do not further the real interest of the consumer. In proof of this, I may state that, not long ago, I saw a copy of an analysis of a manure, the commercial value of which, estimated according to the usual tables, was given at £11 10s. a ton. It may, perhaps be presumed that this manure is manufactured under peculiarly favorable circumstances; but this is not an exceptionable case, for the calculated value of certain superphosphates rich in soluble phosphate of lime is generally £2 or £3 higher than the price at which they are actually sold. On the other hand, it is no unusual occurrence to meet with really good and cheap fertilizers, which, submitted to ordinary commercial analysis, give apparently unsatisfactory results, inasmuch as their value, when calculated according to any of the approved tables, is set £1 to £2 lower than their true money value. Recent experience has convinced me that the buyer may now justly expect something more in a manure than the mere agreement of its calculated value with the price at which it is actually sold. It

is comparatively speaking, easy to prepare a manure say at £6 a ton, the calculated value of which amounts to the same sum; but such agreement, in my opinion, is no guarantee that the manure is really worth that price. It is well known to all acquainted with the peculiarities of the trade in artificials that many samples which, as the saying is amongst manufacturers, "analyse well," can be produced at a cheaper rate than others which do not analyse so well, but which, nevertheless, show a better result in the field, and possess a higher agricultural and commercial value.

I should much regret if these observations should induce any one to deny the utility of submitting artificial manures to chemical analysis. Without a correct analysis, not even an approximate estimate of the value of a manure can be given; it is, therefore, and always will remain, the most important and the most indispensable instrument in conducting such an enquiry; but there are other data likewise to be taken into consideration before the true money value of manures can be determined.

Believing chemical analysis to be of the highest practical utility, and fearing that discredit may be brought upon it by our "Manure Calculators," I am anxious to place in a proper light the ordinary money calculations which are given by most chemists with the analysis of artificial manures.

These calculations in many instances, do not deserve the name of valuations, for instead of indicating what the manure is worth to the consumer, and at what price it can actually be bought in the market, they show an imaginary value, which, in some cases, is much lower, and in others much higher, than the price at which the manure can be supplied. Take, for example, the following numbers which express the

*Composition of a Sample of Superphosphate selling at £6 10s. a ton.*

|                                                |        |
|------------------------------------------------|--------|
| Moisture .. .. .                               | 14.62  |
| *Organic matter and water of combination ..    | 9.92   |
| Bi-Phosphate of lime .. .. .                   | 18.02  |
| (Equal to bone earth rendered soluble, 28.12.) |        |
| Insoluble phosphates .. .. .                   | 8.46   |
| Sulphate of lime .. .. .                       | 42.15  |
| Alkaline salts .. .. .                         | 2.34   |
| Insoluble silicious matter (sand) .. .. .      | 4.49   |
|                                                | 100.00 |
| * Containing nitrogen .. .. .                  | .59    |
| Equal to ammonia .. .. .                       | .71    |

An exceedingly simple method by which the value of artificial manures is calculated is to regard the analysis as representing the composition of 100 tons of manure, and to multiply each constituent by its assumed market price per ton, and then to add up all the products. We thus obtain by calculation the price of 100 tons, and, by dividing this by 100, the assumed value of one ton.

The following list gives the price per ton of each constituent, according to the valuation

tables of Professors Way and Anderson, and Mr. Nesbit:

|                              | Way. |       | Anderson |       | Nesbit. |       |
|------------------------------|------|-------|----------|-------|---------|-------|
|                              | £    | s. d. | £        | s. d. | £       | s. d. |
| Organic matter .. .. .       | 1    | 0     | 0        | 0     | 1       | 0     |
| Soluble phosphate (i. e.)    |      |       |          |       |         |       |
| bone earth rendered soluble  |      |       |          |       |         |       |
| by acid .. .. .              | 33   | 0     | 30       | 0     | 24      | 0     |
| Insoluble phosphates .. .. . | 7    | 0     | 7        | 0     | 8       | 0     |
| Sulphate of lime .. .. .     | 1    | 0     | 1        | 0     | 1       | 0     |
| Alkaline salts .. .. .       | 1    | 0     | 1        | 0     | 1       | 0     |
| Ammonia .. .. .              | 56   | 0     | 60       | 0     | 60      | 0     |

Calculated according to Professor Way's table, we obtained the following value for this superphosphate:—

|                                    | Value per ton. | £  | Total | £      |
|------------------------------------|----------------|----|-------|--------|
| Moisture .. .. .                   | 14.62 by       | —  | —     | —      |
| *Organic matter .. .. .            | 14.62 by       | 1  | —     | 14.62  |
| Bi-phosphate of lime .. .. .       | 18.02          | —  | —     | —      |
| Equal to bone earth                |                |    |       |        |
| made soluble .. .. .               | (28.12) by     | 33 | —     | 927.96 |
| Insoluble phosphates .. .. .       | 8.46 by        | 7  | —     | 59.22  |
| Sulphate of lime .. .. .           | 42.15 by       | 1  | —     | 42.15  |
| Alkaline salts .. .. .             | 2.34 by        | 1  | —     | 2.34   |
| Insoluble silicious matter .. .. . | —              | —  | —     | —      |
|                                    | 100.00         |    |       |        |
| *Containing nitrogen .. .. .       | .59            |    |       |        |
| Equal to ammonia .. .. .           | .71 by         | 56 | —     | 39.76  |

Calculated value, £10 16s. per ton

£1086.05.

Proceeding in the same manner, the price of the same superphosphate will be £10 according to Dr. Anderson's, and £8 6s. according to Mr. Nesbit's table. Whether we take Professor Way's or Anderson's or Mr. Nesbit's tables, in either case there is a great discrepancy between the actual price at which this article is sold and its calculated value. Similar, and in some cases still greater, differences can be noticed in the calculated and actual value of many samples of superphosphate, especially those made exclusively from coprolites and other mineral phosphates. It evidently appears from these facts that at the time when Professors Way, Anderson, and Nesbit drew up their valuation tables soluble phosphate of lime could not be manufactured so cheaply as at present, and that consequently the price per ton of soluble phosphate now requires to be reduced, especially if Professor Way's or Dr. Anderson's figures are taken as standard values in the calculation, and the manure under consideration is entirely or principally made from mineral phosphates.

I purposely abstain from giving an amended price for soluble phosphate of lime, for such a price cannot be fixed in a general way and then applied to particular instances.

The fact is, the commercial value of phosphate of lime, like that of many other minerals, depends in some measure on the source from which it is derived, and the nature and the amount of other substances with which it is associated. Thus, soluble phosphates cannot be produced at as low a price when made from bones as from mineral phosphates. Then why not make it in the cheapest possible form? is a question which

naturally suggests its if, but which is answered by the fact that in many instances bones partially dissolved in oil of vitrol produce a better practical result on the turnip crop on light soils than a mixture containing an equivalent amount of soluble phosphate made from coprolites and insoluble bone phosphate.

We thus see that it is not enough that there should be a certain amount of soluble and insoluble phosphate in a turnip manure, but that the very source from which the fertilizer is obtained affects its agricultural as well as its commercial value.

A superphosphate containing say, 15 or 18 per cent. of soluble, 15 per cent. of insoluble phosphate in the shape of bone, and  $2\frac{1}{2}$  per cent. of nitrogen can be made much cheaper by producing in the first place the soluble phosphate from coprolites, and mixing the coprolite superphosphate afterwards with bone-dust and a certain quality of shoddy, or a similar nitrogenous refuse material, than by making it entirely from bones. But as superphosphate from bones has a better effect in the field, and costs the maker more money, and thus has a higher commercial value than a manure which on analysis furnishes the same amount of soluble and insoluble phosphate and nitrogen, the constituents of a bone superphosphate, and amongst them a soluble phosphate of lime, must have a higher commercial value in this combination than in mere mixture of dissolved coprolites, bone dust, and a nitrogenous refuse matter.

Again up to 28 or 30 per cent. of soluble phosphate (i. e., bone earth rendered soluble by acid) may be produced in a superphosphate simply by mixing phosphatic materials with a certain quantity of sulphuric acid; but if a much higher proportion of soluble phosphate is required, recourse must be had to more complicated and expensive chemical processes; and these processes, of course, add to the expense at which the soluble phosphate is obtained in highly concentrated manures, such as Messrs. Burnard, Lack & Co's concentrated superphosphate, which contains no less than 44 per cent. of soluble phosphate.

Notwithstanding the increased expense in producing the soluble phosphate in a higher concentrated superphosphate, it may be good policy and economical to the consumer to prepare such concentrated fertilizers for exportation or for application in localities where the cost of carriage of the diluents in or inary manures amounts to much more than the extra expenses of the process of preparing the effective constituents in a highly concentrated form.

Since then, in peculiar cases such a concentrated manure has a higher relative value for the consumer than an ordinary sample containing 18 to 22 per cent., and is prepared at greater cost by the manufacturer, it certainly would not

be right to estimate the money value of the soluble phosphate in both at the same rate.

Another reason which deters me from attempting to fix a price for soluble phosphate—or, indeed, for any manuring constituent—is, that the price of the same substance in the same form varies continually from a variety of causes.

The commercial price of the raw materials employed in the manufacture of manures, like that of everything else, is dependant upon demand and supply, and regulates itself accordingly. The consumer, in my opinion, has a far better guarantee for a supply of cheap fertilizers in the competition of respectable firms than in the publication of any fallible, because constantly changing, price list. There exists, moreover, the danger that the price lists fixed by chemists of standing are frequently applied by others whenever it suits their purpose long after they have become obsolete. In the interest of the farmer I feel, therefore, bound not to publish an amended price list of fertilizing matters.

(To be Continued.)

## Agricultural Intelligence.

### Thorndale Short-Horn Blood.

The *Country Gentleman* in his last issue observes in reference to this celebrated stock at a recent sale in England:—

Farther testimony is given in our last foreign mails to the vale of the Thorndale blood. "Another high—and what is better still, a thoroughly honest—average has been added to Short-Horn history," says the *Mark Lane Express* in opening its account of the sale of Mr. Hales' herd at North Frith, Sept. 24th. Mr. H. was the purchaser last year, it will be remembered, of the 4th Duke of Thorndale, sent to England by Samuel Thorne, Esq., at 400 guineas (say \$2,000); and his wisdom in paying such a price has been fully vindicated in the results of his own sale. The 4th Duke it seems, was started at 200 guineas, and ran up rapidly, between the bids of Capt. Gunter and Lord Exeter's agent, until he was finally knocked down to the latter at *four hundred and ten guineas*—in other words, Mr. Hales has had more than a year's use of the bull, and disposes of him now for \$50 more than he paid Mr. Thorne in 1861.

There were also sold at the same time several calves sired by "4th Duke," as follows:—

#### HEIFER CALVES.

|                                                         |        |
|---------------------------------------------------------|--------|
| 2d Kentish Gwynne, calved Feb. 15, 1862, for 41 guineas |        |
| Heiress, do. June 4, . . . . .                          | 64 do. |
| Perfection, do. July 19, . . . . .                      | 35 do. |
| Concord, do. Sept. 20, . . . . .                        | 16 do. |

#### BULL CALVES.

|                                               |             |
|-----------------------------------------------|-------------|
| Athelwald, Calved May 12, 1862, for . . . . . | 26 guineas. |
| Marmion, do. July 17, . . . . .               | 155 do.     |
| The Friar, do. July 15, . . . . .             | 26 do.      |
| Fastus, do. July 23, . . . . .                | 50 do.      |
| Clifford, do. Aug. 16, . . . . .              | 30 do.      |

Here are nine calves, the average age of which on the day of sale, according to our computation, was only 2 months 25 days, sold at an average price only a small fraction less than 50 guineas each, or very nearly \$250.

There were 22 head of other females sold—including young and old, and all but four of them calved in 1860 or previously—which brought an average price per head of about 56 guineas—one of them, "Moss Rose," by Marmaduke out of Cambridge Rose 6th, going for 245 guineas. Excluding her the average for the other 21 is lower than that for the four young heifers sired by "4th Duke." Of the bulls, beside 4th Duke and his five calves, there were four sold at an average of 43 guineas each. But in referring to the prices at which the cows were sold, it should have been remarked that 14 of them had been served by "4th Duke," which would of course have added considerably to the prices they commanded.

## Horticultural.

**PROCEEDINGS OF THE FRUIT GROWERS' ASSOCIATION** of Upper Canada, at the General Meeting held in the Agricultural Hall, corner of Yonge and Queen Streets, Toronto, on Wednesday, Nov. 12th. 1862.

The meeting was called to order by Mr. Vice-President Leslie, the President, Judge Logie, being absent. After the reading of the minutes of the last meeting, the Association proceeded to discuss and determine the varieties of Plum best suited to our climate.

### JEFFERSON PLUM.

Mr. Arnold, of Paris—Prefer the Jefferson to all others. It ripens about the middle of September, is of good quality, while the tree is hardy and grows well.

Mr. Gray, of Toronto—I do not think it quite as desirable for this locality.

Mr. Geo. Leslie, jr., of Toronto—Is a large, fine Plum, but not so desirable here as the Washington.

Mr. Laing, of Hamilton—I do not find it the best, would prefer many other varieties before it.

Mr. Johnston, of Norval—I do not find it to do well. It did not succeed with Mr. Young of Georgetown. In flavour and productiveness is not equal to some others.

Mr. D. W. Beadle, of St. Catharines—It has so far proved to be but a moderate bearer, and the tree a very poor grower, not much better than the Green Gage.

Recommended for further trial.

### GREEN GAGE.

Mr. Arnold, Paris—The fruit is too small for market, though of the highest flavor. The tree is a very slow grower, and exceedingly subject to the black knot.

Mr. Gray, Toronto—The tree is a very slow

grower and requires very good cultivation, but the first is of the first quality.

Mr. Geo. Leslie, jun., Toronto—It is the worst grower of all the plum trees in cultivation, yet one of the highest flavoured of plums.

Mr. Laing, Hamilton—The fruit is of the best quality, tree good bearer, dwarf habit, and requires good cultivation.

Mr. Johnston, Norval—is one of the slowest growers and most abundant bearers, but the fruit is too small, and not desirable when we have so many other varieties that are larger and better for market purposes.

Mr. D. W. Beadle, St. Catharines—It must be admitted that in excellence of quality the fruit is unsurpassed, but the tree is a most miserable grower, and unsatisfactory to nurserymen.

Recommended for general cultivation as a dessert plum.

### WASHINGTON.

Mr. Johnston, Norval—It will not do for this climate, tree too tender and not very abundant bearer.

Mr. Fleming, Toronto—I have seen very good crops about here; the tree thrives well; have fruited it for 25 years and found it quite hardy.

Mr. Bruce, Hamilton—It does well about Hamilton.

Mr. Laing, Hamilton—A very good plum, tree hardy and a great bearer.

Mr. Geo. Leslie, jun., Toronto—Is one of the best; a good grower and good bearer, and hardy tree.

Mr. Gray, Toronto—Know of none that succeed better in this vicinity.

Mr. Arnold, Paris—The tree is perfectly hardy; fruit good, but a very poor bearer.

Mr. Geo. Leslie, sen.—One of the best bearers; an excellent market variety; tree perfectly hardy.

Mr. D. W. Beadle, St. Catharines—I have found it to bear immense crops on sandy soil.

Recommended for general cultivation.

### SMITH'S ORLEANS.

Mr. Keating, Jordan—Is a very good plum; tree hardy, and a great bearer.

Mr. Johnston, Norval—A good bearer, good grower, worthy of cultivation; good for preserving.

Mr. Lea, York—A valuable variety; good bearer.

Mr. Fleming, Toronto—An excellent variety.

Mr. Bruce, Hamilton—It is a general favorite with us.

Mr. Gray, Toronto—Have known it for many years, and have always found it first class.

Mr. Arnold, Paris—Is a good plum, tree a very good bearer, a dessert fruit, not large enough for market.

Mr. Vice P. Leslie, Toronto—Is a medium bearer, but very good fruit, size medium, larger than any of the common blue plums, tree hardy and good grower.

Mr. D. W. Beadle, St. Catharines—A very desirable variety in quality of fruit and growth and hardiness of tree.

Recommended for general cultivation.

## IMPERIAL GAGE.

Mr. Johnston, Norval—Is a good plum, medium quality, size medium, not a sure bearer.

Mr. Fleming, Toronto—A great bearer, not first quality

Mr. Bruce, Hamilton—Bears freely, medium quality, hardy.

Mr. Laing, Hamilton—Most prolific bearer, hardy, but fruit of second quality.

Mr. Geo. Leslie, jr., Toronto—Is a good bearer, but fruit of poor quality

Mr. Gray, Toronto—It succeeds well here, the tree does not seem to be subject to the Black Knot, fruit of second quality.

Mr. Arnold, Paris—I find it to be of the finest flavour, tree a fair bearer, my soil is rather light.

Mr. Vice P. Leslie, Toronto—Very great bearer, very healthy tree, a fine market fruit, though of only second quality.

Recommended for cultivation, particularly on light soils.

## REINE CLAUDE DE BEVARY.

Mr. Arnold, Paris—of the very first quality where the season is long enough to ripen the fruit.

Mr. Lang, Hamilton - a very desirable sort.

Mr. Gray, Toronto—A late but very desirable variety, will keep well and improve after being gathered.

Mr. Geo. Leslie, jr.,—A very valuable late plum

Mr. D. W. Beadle, St. Catharines—The best late plum.

Recommended for general cultivation.

## PRINCES' YELLOW GAGE.

Mr. Gray, Toronto—Is a good plum, bears well, medium size, of second quality.

Mr. Arnold, Paris—Medium size, medium bearer and second quality.

Mr. Laing, Hamilton—A fair quality and a good bearer.

Mr. Geo. Leslie, Toronto—It is the least liable to the black knot, size and quality medium.

Mr. Fleming, Toronto Is a second quality plum, but the tree is a good bearer and grows well.

D. W. Beadle, St. Catharines—It seems to flourish in the County of Lincoln.

Recommended for general cultivation.

## LOMBARD.

Mr. Arnold, Paris—The fruit is of medium size, and not best quality, but will resist the attacks of the Curculio the best of any variety, the tree is very productive.

Mr. Bruce, Hamilton—Is a great bearer, free grower and a very valuable sort.

Mr. Johnston, Norval—I have a very high opinion of this variety, it is very hardy, very prolific, very free from Black Not and from every other disease. Is the best adapted to Canada of any known variety.

Mr. D. W. Beadle, St. Catharines—While I do not consider the quality of the fruit as fine in flavor as many other sorts, yet I do esteem it

the most valuable and desirable for general cultivation. The tree is remarkably healthy and if not perfectly exempt from the Black Knot is much less subject to it than many sorts. On a sandy soil where the Curculio is most troublesome, this variety never fails to mature a good crop in spite of that insect.

Recommended for general cultivation.

## COES GOLDEN DROPS.

Mr. Johnston, Norval—Is very free from disease, late sort, and very desirable on that account, of good flavour, juicy.

Mr. Fleming, Toronto—Very valuable, should be in every collection

Mr. Gray, Toronto—Very desirable

Mr. Vice P. Leslie of the first class.

Mr. Arnold, Paris—I should call this the best late plum

Recommended for general cultivation.

## LAWRENCES FAVORITE.

Mr. Geo. Leslie, jr., Toronto—Very early and of very fine quality, one of the best for table, tree hardy.

Mr. Gray, Toronto—Fine early dessert fruit, hardy

Mr. Johnston, Norval—A very good plum, early.

Mr. Vice P. Leslie, Toronto—Very sweet and fine, but small size.

Recommended as an early variety.

Mr. Johnston, of Norval spoke of the Pond's Seedling, that he believed it to be one of the best varieties now grown, the largest plum, color red or a yellow ground stone small, the flavor very sweet and rich, fruit will keep long after being plucked, tree a very thrifty grower, and requires a good strong soil with high cultivation

This variety not having yet been furnished in Canada the Society took no action upon it. Mr. Johnston stated that he had resided in Norval only about two years, and that he had not seen the fruit in Canada but at the place of his former residence near Rochester.

## YELLOW EGG PLUM.

Mr. Vice P. Leslie, Toronto—This is one of the very best for cooking and preserving; trees hardy, good bearers and rapid growers.

Mr. Arnold, Paris—A showy, coarse fruit, for preserves, tree tender with

W. G. Leslie, jr., Toronto—Good for preserving, and market.

Mr. Gray, Toronto—One of the best for cooking and market; tree hardy.

Mr. Laing, Hamilton—Very handsome and profitable.

Mr. Bruce, Hamilton—Hardy and valuable for market.

Mr. Fleming, Toronto—Very hardy, good bearer, excellent for preserving.

Mr. Johnston, Norval—Excellent market variety; hardy tree, fruit coarse.

## RECOMMENDED FOR GENERAL CULTIVATION.

The Association then proceeded to the dis-

cussion of the question, which are the six best varieties of Grape for open air culture in Canada? Gentlemen were requested to write down the names of such as they thought most desirable, and hand the list to the Secretary.

Mr. Gray, Toronto—Delaware, Concord, Hartford Prolific, Diana, Isabella, Ontario.

Mr. Arnold, Paris—Concord, Diana, Delaware, Rebecca, Ontario, Hartford Prolific.

Mr. G. Leslie, jr, Toronto—Delaware, Ontario, Concord, Hartford Prolific, Rebecca, Diana.

Mr. J. W. Keating, Jordan—Delaware, Rebecca, Concord, Diana, Ontario, Clinton.

Mr. Johnston, Norval Delaware, Concord, Isabella, Dura, Clinton, Ontario.

Mr. McNab, Hamilton Rebecca, Sweetwater, Delaware, Diana, Hartford Prolific, Clinton and Hamilton, supposed to be a seedling of the Isabella.

Mr. W. J. Keating, Jordan—Delaware, Sweetwater, Clinton, Diana, Rebecca and Concord.

Mr. Vice P. Lesslie, Toronto—Concord, Delaware, Diana, Hartford Prolific, Ontario, Isabella

Mr. D. W. Beadle, St Catharines—Said he was not yet prepared to recommend six varieties, but would name only Concord, Rebecca, Delaware and Hartford Prolific, as being from his experience most likely to give satisfaction

A conversational discussion then ensued upon the best mode of planting, pruning, training, and cultivating the grape vine in the open air, during which much valuable information was elicited

Upon motion of Mr. J. W. Keating, seconded by Mr. Fleming, it was unanimously resolved, that Mr. Charles Arnold, of Paris, be requested to prepare a paper upon the open air culture of the grape, to be read at the next meeting of the Association.

The Secretary read a letter from Mr. S. B. Freeman, of Hamilton, relative to an apple found growing on his father's farm, specimens of which were exhibited. Upon testing the specimens, they were found to be of excellent quality, and the Association requested the Secretary to publish a description of the apple, and give it the name of the Freeman apple, deeming the fruit worthy of more extended trial

**Description of the Freeman Apple.**—Size small; color, light yellow, with a bright blush on the sunny side, thickly sprinkled with small russet dots or specks. Calyx closed, set in a shallow finely plaited basin. Stem long and slender, set in a deep cavity. Flesh tender, fine grained, juicy and breaking. Flavor a very pleasant, sprightly, sub-acid. Quality "very good," if not "best."

Mr. Fleming produced a branch bearing two apples in such close contiguity that they touched each other, the one a Pomme Grise, the other yellow, with a red cheek and wholly free from russet.

The Secretary read a paper from Mr. Laing, of Hamilton, which is published below. On motion of Mr. Arnold, the thanks of the Society were presented to Mr. Laing for his interesting

paper, with the request that he would allow it to be published in the Transactions of the Association.

On motion of Mr. Laing, seconded by Mr. Keating, the Secretary was requested to communicate to the Board of Agriculture the thanks of the Association for their kindness and liberality in granting them the free use of their Hall for the purposes of the meeting.

Mr. Geo. Leslie, of Toronto, exhibited 25 varieties of apple. Mr. Johnston, of Norval, 20 varieties of apple. Mr. Keating, of Jordan, 3 varieties of apple. Mr. McNab, of Hamilton, 4 varieties of grape. D. W. Beadle, of St. Catharines, 5 varieties of pear, and among them the Fulton, a very hardy sort, originated in Waine, of good quality, and promising to be very valuable for Canada.

On motion adjourned to the Annual Meeting, to be held in the City of Hamilton on the third Wednesday (the 21st) of January, 1863.

### Remarks on the Planting and Culture of Fruit Trees.

**MR. PRESIDENT AND GENTLEMEN.**—At the meeting of the Association held in St. Catharines in July last, a remark of importance was made by Dr. Craigie, which was passed over without much notice. At this I was somewhat astonished, as it applied so specially to the most essential points of fruit culture, such as situation, aspect, soils, preparation of soils, planting, pruning and the general management of the orchard. It is a well-known fact that to secure success in anything, right measures must be adopted and the proper means used. It must also be very clear to all, that a knowledge of, and a proper understanding on those points are absolutely necessary. I think I am justified in saying that much ignorance exists on this matter all over the country, therefore the sooner something is brought out to bear fully on it, the better, and it would be a great matter for the benefit of this Association and for the good of the Province if every member would lay before this Board what practical knowledge he may possess, so that it may be enabled to point out to the country a sure and safe course to pursue. I have been connected with Horticultural and Agricultural pursuits for the last 40 years, and have during that period practised professionally in Scotland, England, Ireland and upwards of six years in this country, and I maintain that more failures are caused by ignorance, mismanagement and a misconception of what Dr. Craigie referred to than anything else that I know. Thousands of good healthy young trees are yearly put out into bad situations and unsuitable soils, where they soon die, or linger out a few years of an unprofitable, miserable existence. Every fruit tree has its own peculiar kind of soil such as it likes, and which practical men may know, but many of the agricultural community do not, therefore it becomes the

duty of this association to tell them. With a view to this I shall notice the heads of this subject by a few practical remarks from my own experience and observations.

First, then, as to situation. It should neither be too high nor too low, if too high the trees are exposed to sharp cutting winds, if too low they will be subjected to hard frosts and damp apours, all of which are very injurious. This the nature of the location with judgment must determine. A south and south-east aspect is invariably preferred in the old country, here the south and south west are so.

Abercrombie observes, "An open aspect to the south-east is itself a point of capital importance in laying out a garden or orchard"

Downing says, "It is difficult to give any precise rules as to aspect." "Perhaps," he says, "the very best aspect on the whole is a gentle slope south-west, because in such a position the trees, when in blossom, are sometimes protected from the bad effects of the morning sun after spring frosts." Good shelter should in all cases, if possible, be provided.

Drainage and trenching are the next things in order as preparatory operations. Of whatever nature the soil may be, if the least damp or retentive, drainage is necessary. I may say, whether damp or not, unless on a dry substratum of lime stone. The good of drainage is not altogether confined to carrying off the water and drying the land. The circulation of air that continually passes through the ground will be found productive of the most beneficial effects. Let the drains be put in of tiles  $2\frac{1}{2}$  or 3 inches, say 20 feet apart, more or less, as circumstances may direct, and from 3 to 4 feet deep according to the nature of the subsoil,—place vertical air tubes made of tile at all the corners and in the straight lines at every 100 yards; the tubes to be inserted into the bottom tiles, and to have wood stops or plugs of sufficient length or height so that they may easily be seen above the ground and used when required. Care must be taken if a plough or cultivator be used not to disturb them. This mode of drainage has a wonderful effect on all kinds of soils, and in no way is it more marked than in ground under fruit cultivation. It may be considered expensive, but if well done will very soon amply pay for the outlay. All orchard grounds must be well trenched either by the plough or spade,—the latter is the best. Then have it properly prepared for the different kinds of trees—a few of which I shall notice, with what I consider their suitable soils. All fruit trees like loams, some of a light nature, others more heavy and strong—soils of a calcareous nature are desirable for all, particularly for stone fruits. Stiff clays of all kinds are considered injurious to all trees, and particularly so for fruit, unless thoroughly drained and pulverised and brought into a proper state of fertilization. When so it is most productive, very durable, and will answer well with many of the kinds.

The Apple prefers a rather soft loam, containing a small portion of sand with a due proportion of good, well decomposed, stable yard manure. In such a soil the trees grow very clean, are productive, and flourish long. The fruit attains good size, colour and flavour, and is not subject to disease. It is not necessary that the soil should be very deep, say from 20 to 24 inches, even less in some locations. Depth is more necessary in this country than in the old, on account of the long terms of dry weather and hot scorching sun.

The Pear on a stock of its own species requires a deeper and stronger soil than the apple—more rich and mellow. In my own experience I have seen the pear succeed remarkably well in a drained pulverised clay, the trees healthy and productive. The Quince stock thrives best in a rich moist soil, but of course drained. In both cases plenty of good manure is necessary.

The plum answers best in a medium soil, not too heavy or too light. I have known it succeed very well in a compost of light loam, garden soil and road-scrapings.

Cherries delight in rather a sandy soil, but not gravelly—in the latter they will grow for a few years but soon die. The Cherry will thrive in mostly any soil if rich enough and dry.

Of the Peach it may be said that of late years it has been almost a failure, in some places totally so. This season it looks better. I believe that if the ground into which the peach is to be planted, be of a right nature, well sheltered, properly drained, and prepared, the trees cultivated on the dwarf principle, and well attended to during the summer all would yet be well. Unless the soil is in a proper state, and the necessary attention bestowed, the trees will not mature their buds nor ripen their wood sufficiently to stand the frosts. The dwarf system of culture has many advantages; the trees are easily protected, handy to go about, and are so completely under the eye that nothing can escape unnoticed. The Peach may be grown of any shape to suit convenience, either as a dwarf, Pyramid, or Bush not larger than a Gooseberry or Currants, and planted in a similar manner. In this way the snow will do much to protect the trees in winter, and their foliage the stem and branches in Summer. Being near the ground the heat is more congenial than it otherwise could be when they are grown higher up, as they in general are almost like broom-sticks, and if not staked, shaken about by every wind, and the stems exposed to the hot scorching sun, which often proves very injurious. The Peach, the Nectarine and Apricot, all answer in a rich calcareous soil.

As orchards have been grown, the trees are far too high in the stems to admit of cultivation and pasturage under them. Trees a

less distance apart, branching within two or three feet of the ground, and properly kept under the knife and thumb, would be found preferable, and more profitable, though not not admitting of pasturage or cereal crops.

*Planting*, or rather transplanting. To secure success, this operation ought to be done with great care, otherwise a failure is sure to be the result. Whether the operation be performed in the spring or fall, have all things in readiness; in case of need, have a prepared planting compost at hand, and the pits all dug. In my early days it was the custom to lay a circular space of from 3 to 5 feet diameter of slate or flag stone under the trees, so as to prevent the roots getting down into the subsoil. At the present time in England, on some occasions, they concrete or flag the vine and fruit tree borders, a very excellent plan where it may be necessary. In ordinary orchard-planting such a mode is not much practised, neither is it requisite if the ground be well drained and the planting properly executed, carefully spreading out all the roots, giving them the right direction which they will naturally retain afterwards, keeping near the surface for the benefit of the heat and moisture; great care ought to be taken in lifting the plants not to injure the roots. Avoid deep planting, have the pits wide enough to receive the roots when extended so that none of them rest on the sides of the pit. Before planting prepare the roots by pruning off all the injured or broken parts, taking care of all the finer fibres; cover the bottom of the pit with the prepared compost, raising it a little in the centre, then carefully spread the roots out on the bedding stuff. If the natural soil be not good, plant and fill up the pits with the composts, otherwise use only a little, carefully working it in with the hand amongst the roots; afterwards fill up or spread out the common earth, pressing it down with the foot. It is a very common practice to have a trough or tub with a puddle made from the drainings of the dung hill ready at hand, in which the roots of the plants are immersed before planting, this is very advisable particularly, if the roots be dry. When the whole is completed, if the plants are standards they ought to be staked, and the ground over the roots mulched with litter from the stable-yard. If planting be done in fall it should be performed as early as the plants will admit of being lifted (as a general rule from the 15th of October until the freezing up of the ground) in order that they may have time to take to the ground, and the roots form spongeoles before the winter sets in.

I cannot conclude this paper without noticing the necessity of a careful selection of trees in varieties suitable for the location and climate. It is also very necessary that the public be induced to deal with respectable

nurserymen for their trees, and warned to have on no account or consideration anything to do with the Fruit tree jobbers, or, as they term themselves, *agents* for the sale of Fruit trees. It is not only disappointing, but also a very serious loss when a young orchard comes into bearing to find the fruit almost worthless. Nurseries or nurserymen are not all alike commendable, no more are their trees, but the respectable and those of standing I trust will, and ought for their own interest do what is right. Every purchaser ought to satisfy himself that those from whom he purchases are the duly authorised agents of some responsible and respectable nursery, and make sure in getting good, clean, well-rooted healthy trees, taking care to avoid all prong or carrot-rooted plants, selecting plants of good shape, with well furnished fibrous roots. Such will be found in all well managed nurseries.

GEORGE LAING.

Hamilton, 11th Nov., 1862.

P. S. I may at some future period have something to say on the general management of the orchard, pruning, training, &c.

G. L.

### Peterboro' Horticultural Society.

We are glad to learn that this young Society is making steady and healthful progress. The autumnal show (the report of which got for a while mislaid), considering the lateness of the season, was on the whole quite satisfactory; comprising flowers, fruits and vegetables, highly creditable to their producers.

The flowers were good, especially a new *Petunia*, *marginata*, exhibited by Mrs. Robert Nicholls, to which the judges awarded the first prize as a "specimen plant." The collections of Asters raised by Sheriff Hall and Mr. Cooney, of Verbenas by Mr. William Hamilton, and of Cock's-combs by Rev. J. W. Beck were much admired; and Captain Rubidge and Mr. Scobell afforded a profusion of cut flowers of considerable merit.

The exhibition of Fruit was very superior to that of last year. Mr. Carver's Peach-plums and Egg-plums were especially praised, and Mr. Gilmour's collections of Apples, Pears and Plums deserved and received a large share of notice.

The collections of Vegetables were not so large or so good as heretofore, owing chiefly to the season. Mr. English placed some fine tomatoes upon the table, and a new kind of Savoy Cabbage, the "Fine Waterloo," grown by Mr. Giles, is a great improvement on the older and coarser sorts.

There was a large attendance in the evening when the attraction of music was superadded to the Floral display, two senses being thus simul-

taneously gratified; and such of the remarks of the visitors as reached our ears were calculated to inspire a hope that those who honored the Exhibition with their presence were not dissatisfied with the effort made to please them.

At 9 o'clock p. m., the President of the Society, the Rev. Vincent Clementi, addressed the visitors. He took occasion, in behalf the Society, to thank the Mayor for the very cordial manner in which he had granted the gratuitous use of the Town Hall for the purpose of the Exhibition; and Mr. Philp and the members of the Peterboro' Band for their valuable and unrequited services.

He intimated that he should, at the next Annual meeting, recommend that the Horticultural Show be held in future at an earlier date, when flowers, with such fruits and vegetables as are in season, may be exhibited to the greatest advantage; an opportunity for the display of the later products of the garden being afforded by the Agricultural Association whose show takes place early in October.

## The Dairy.

### Josiah Quincey's Milk Farm.

*(Abridged from the Boston Cultivator.)*

The estate in question is that of the Quincy family, in the town of Quincy, the venerable head of which has lived so long to enjoy the respect of the community for his valuable public services and the fruits of his labours. The farm is one of the finest in New England, having been in the possession of the family for many generations, and the title obtained from the Indians. The land lies in one body of three hundred acres, as level as that of a western prairie. The drive from the public way to the mansion-house is through long rows of magnificent trees, for a quarter of a mile, most of which were planted by the patriarch who yet lives to admire their proportions, and take delight under their shadows.

The whole estate is devoted almost entirely to the business of the dairy. Some 400 tons of hay are cut upon it, the land having been brought to that degree of productiveness as to yield from two to three tons per acre; and the amount of other crops cut for green fodder is probably much larger. Corn, millet, barley, rape, and other grain and plants are cut green, yielding in some instances an enormous amount to the acre.

The number of cows kept ranges from one hundred to one hundred and thirty. They are all stalled in a large barn, one-half or more on the main floor, facing each other, and the remainder in the basement on either side of the main building—the centre under the main

floor being reserved as a manure cellar. On the main floor there is the best ventilation, the large doors at either end being open almost continually, not excepting the winter, when it is found to be too warm to keep them closed. Besides this ventilation, there is an opening through the lofts, and a large ventilator upon the top of the barn. On the lower story, although the ventilation may not be so perfect, it is very thorough, the cows facing the openings on the side of the building. They are bedded with sand, obtained on the estate, and this is believed to be advantageous in many respects. The animals are kept well curried and in good order.

In regard to their feeding and habits, they are kept within doors all of the time, and fed entirely in their stalls. This is found to be the most convenient on an estate entirely open, within one enclosure. They are fed five times a day, and turned out into a yard adjoining the barn for three or four hours in the forenoon, a shed open to the south protecting them from storms. The only exception to indoor feeding is in the fall, when they are turned out for six weeks, with an attendant to keep them from uncut crops. This feeding within doors, and keeping them shut up so much, is not believed to be injurious, as cases of sickness among them are rare. Whether or not there is such a disease as the pleuro-pneumonia, this herd has so far entirely escaped it, although it is reported to prevail on an adjoining estate, none of the cows coming in contact with their neighbours. With such a disease among so large a herd, sad havoc would soon be made.

In the morning and at night they are fed with two quarts of grain or cotton seed meal, the grain being a mixture of corn, meal, and oats, the meal being believed to be of too heating a character to be eaten alone. Their other feed three times a day is of green fodder, generally mixed, and alternating from grass, clover, corn, millet, rape, &c., each being fed with the same food at the same time. A meal of salt hay is given occasionally, and to make the green fodder extend as far as possible through the year, early and late crops are raised, and barley is cut green, salted, and laid away. A narrow watering trough runs before each row of cows, covered, and they are at liberty to drink at all times, a cover of the trough before each cow being easily raised by her. This water is raised by a ram from a brook some fifty rods from the barn, and the supply may be increased or lessened by faucets at the ends of the troughs. In winter an infusion of steam takes the chill from the water, too much cold tending to lessen the quantity of milk given by the cows.

The cows are selected for their milking qualities, without regard to breed. They are

all in early pure natives with an occasional mixture, the natives and, the Ayrshire being esteemed as the best milkers. They are generally from Vermont and the upper part of New York, and a change is made of from thirty to forty yearly. No cow is desired under five years of age, and she is kept so long as she proves to be a good milker, and when she falls below five or six quarts a day she is fatted for market, and will bring enough beef to replace her with another good milker. There are several of the cows who give fifteen quarts a day at the present time, eight or ten being the average. There must necessarily be some who are dry, and with calf; these are pastured within sight of the estate, on a peninsula, where they are easily secured. There are at times from thirty to fifty so pastured. The largest number kept is in winter, when there is the greater number of customers for milk, and the yield is nine hundred quarts per day, lessening in summer to seven hundred.

Immediately upon milking, the milk is put through a large strainer into cans, and the cans placed in a large trough with ice; when the animal heat is driven out of the milk, the cans are closed up. They are then taken to a building devoted to dairy purposes, in which there is a large well. The well is twenty-two feet deep, with seven feet of water, quite cool. This well is divided, making each part about square. A platform containing the cans of milk, about two hundred quarts each, is lowered down so that the top of the can only is above the water. Milk has been kept good four days in warm weather in this well. But it is not designed to keep here long as much as it is to keep it cool while on hand. The morning's milk of each day is kept in this well, and with the night's milk supplies the customers the next day. The consumer has the satisfaction of knowing that the milk cannot be two days old before a new supply comes, which cannot be true of the mixed dairies picked up at a distance of fifty or a hundred miles on the railroads. This milk is supplied to customers in this city by two teams, which leave the farm about two o'clock in the morning and which deliver no milk except that furnished from this farm. It must be obvious, too, that there can be little difference in the quality, the cows having the same feed. In some instances where families desire the milk of the same cow for their children, cans of their own are provided, in which the milk is kept separate from that of any other. Four horses are required for the carriage of the milk, two each day, with one day's rest intervening.

In the same apartment with the wells is a boiler, the steam heating the water for washing the cans, and in the winter tempering the water for the cows. Under the floor of the other apartment, where are kept the milk carts,

is an ice house, which furnishes all that is needed for the dairy. The milk cart horses occupy the rear of the building, and outside, facing the south, is a rack for the drying of the cans. Everything is kept in the best condition, leaving the impression that the milk may be relied upon as a genuine article, free from all foreign substances.

## Veterinary Department.

(Conducted by A. Smith, V. S.)

### Prevention Better than Cure.

[The following remarks, relating especially to pleuro-pneumonia, especially apply, nevertheless, to small-pox in sheep; and we extract them therefore from Mr. Gamgee's lately published work.\*]

The great essential in attempting to mitigate losses amongst stockowners is to study the means of prevention. On this point we have been very deficient in Great Britain, not as regards the epizootic lung disease, but other forms of cattle murrain.

These imported plagues in poorer countries than ours, lead governments to establish *cordons militaires*, to slaughter and bury diseased animals, and to compensate individuals for their loss. The whole country is under careful inspection, and persons are bound to report the appearance of a contagious disease, or submit to the infliction of a severe penalty. Such measures would not find favour here; but are we to fly to the other extreme, to continue from one year's end to the other without perceptible abatement in the mortality amongst our cattle, and not only to manifest the greatest carelessness regarding the presence of contagious disorders, but to favour their spread by permitting frauds of the vilest description?

A farmer goes to the market and buys a lot of lean cattle; shortly after purchase pleuro-pneumonia breaks out, and as the condition of the animals prevents a good price being obtained from the butcher, he sends the whole to the market again, knowing them to be unsound, and either the lot is transferred to another farm, or sold to a number of purchasers. I have been asked, when the disease has broken out among a lot of yearlings whether they should be sold at once or chanced. The law takes no cognizance of such a case, the practice is advocated and carried out by those who, in ordinary transactions, are scrupulously honest, and yet if you probe the matter you cannot but admit that the selling of a lot of lean cattle affected with a

\* Our Domestic Animals in Health and Disease. Second division.—Organs of Circulation and Respiration. By John Gamgee, Principal of the New Veterinary College, Edinburgh; Author of "Dairy Stock," "The Veterinarian's Vade-mecum," &c., &c. With numerous illustrations. Edinburgh: Thomas C. Jack, 92, Princess Street. London: Hamilton, Adams, & Co.

spreading malady, though perhaps only in the stage of incubation, is defrauding the purchaser and the nation. Some may find relief under the absurd supposition that diseases are not catching; but if any such individual is cross-questioned it will be found that he would not have sold the cattle had he not believed that the whole were in imminent danger, and that the majority must die.

It is evident that such a practice is totally opposed to the nation's best interests; but in reality the public interest is made up by the sum of private interests involved; and although at first sight the individual threatened with loss thinks he had better clear out his bad stock, he may at his next purchase, be not a whit better off, from the very practice he has encouraged and followed out. I have satisfactorily found, in numerous cases, that it is unadvisable to clear out a farm stock, and local means can be adopted to check mortality with the greatest success.

But there is another way in which the owner of diseased animals is permitted to spread contagion. He is allowed to send them by railway, to entrust them to a salesman, and to expose them amongst healthy cattle that are to be transferred to different parts of the country for grazing purposes. Fat or not fat they are exposed without restriction, and any amount of good stock may be contaminated. A dairyman in town has a cow taken seriously ill. A number of hungry fleshers are ready for her at a good sum, but in order to cause keen competition, the poor animal is walked into the public market, and stands with a number like herself amongst store animals. Such a practice is as reckless and horrible, as if a patient with small pox were placed amongst a lot of non-vaccinated people for hours together; and the healthy cows just fresh from the country are especially prone to imbibe a deadly virus.

I am conversant with another evil demanding instant suppression. A cow-dealer may buy a fine lot of healthy cows for the town. They are trucked, and somewhere near their destination a truck, containing diseased animals is attached to the train. I know an instance of a dealer, who, with three large trucks full of fine English cows, had, on reaching Carstairs, to submit to their being placed behind a lot of three suffering from lung disease. Imagine how favourable the breeze and the proximity of those animals to spread contagion! It should be a standing rule that every cattle-truck should be washed thoroughly, and sprinkled with an antiseptic substance, before other cattle are exposed in it. There are animal poisons such as that of epizootic apthæ, which may be found to adhere to places, and spread disease with the greatest certainty.

The home trade in diseased cattle is sufficient to keep up for an indefinite period of time pleuro-pneumonia in a country like our own, but I have

specially alluded, in the *Edinburgh Veterinary Review*, to the necessity for legislation to prevent the constant importation of diseased cattle from foreign lands. In the June number for the current year, I state;—Free trade may have its disadvantages. The impetus it gave 25 years ago to the cattle trade led to the introduction of much disease on British soil, and unless some influential men will take an interest in this subject and exert themselves for the common good, we shall continue to import disease, and lose millions by such importations. In an article on pleuro-pneumonia in Holland, which appeared in our last number, and the facts of which was gleaned from a blue book, it is shown how extensively that country is swept by cattle-plagues, whence we chiefly obtain foreign store cattle for our dairies or for feeding purposes. If our imports of live cattle vary from 30,000 to 60,000 per annum, it is evident that there is a wide field for the contamination of our home stock, and this is facilitated 1stly, By the wants of the country throughout its whole length and breadth; 2ndly, By the totally unchecked trade in diseased animals; 3rdly, By the absence of all proper means to detect and counteract disease. If thousands of men were landed from countries infected by yellow fever or other pestilence, and systematically communicated these amongst us, vigorous efforts would soon be made, and even quarantine enforced for our own protection; but we observe precisely such an occurrence as affecting our cattle, and as the country is wealthy enough not to be destroyed by it, the loss is tolerated, and no attention paid to the consequences of a most pernicious traffic.

Free trade is surely not incompatible with an enlightened inquiry as to the countries which are clear of cattle-plagues, and those that are suffering from them. We need not court a trade with that part above all others in Europe, which is overrun with pleuro-pneumonia, and as fat cattle ready to slaughter are needed by us more than lean cattle and cows, which we can breed in such enormous numbers, and better than our neighbours, we do not see why some restrictions on the importation of cattle to be exposed amongst healthy stock here, should not be enforced.

Can a Member not be found in Parliament to move in this matter? The subject is worthy the most anxious and careful study. It has been well proved that epizootics, like epidemics, disappear if permitted to do so, and if they are not encouraged by facilitating contagion, &c. It is also easily demonstrated that the United Kingdom is naturally the most healthy portion of Europe, and in which cattle plagues are only seen as the result of importation. The very diseases which prove so destructive now visited us last century, but trade was not so active, importations were few, and the disorders disappeared.

The veterinary profession in this country has

not hitherto turned its attention to the great questions which affect our national prosperity, and which are purely veterinary in their nature. We must do more than learn how to physic, blister, and operate; we must study prevention. This is the great field for future workers and for men of science, trained to the investigation of laws governing health and disease.

### Veterinary Progress.

The veterinary, if properly educated, would be able to teach the human surgeon much; mutual intercourse would be productive of mutual benefit. It must, moreover, not be forgotten that in the study of physiology, the facilities of experimenting on the brute creation have ever caused human physiologists to engage in the comparative study of animals; and the astonishing fact is that veterinarians have not yet appropriated the stores of learning, which lies interspersed in treatises on the functions of man. There is a very satisfactory explanation of all this, in the fact that observations on the functions of animals and experiments on brutes have only been made and performed with a view to illustrate the physiology of man, and thereby the details of experiments, which were irrelevant in researches so planned, have been lost sight of. Men have generalised boldly, only knowing a limited number of incomplete facts; and it will only be when veterinarians will work seriously at physiology that certain questions, even respecting the functions of man, can be settled. But, though much remains to be done, it is comforting to reflect that Hering, Colin, Chauveau, Gurli, Hertwig, Ercolani, Vellar and a few others, have done enough to render veterinary physiologists renowned; and they prove that the means in our profession for such study are inexhaustible and unrivalled.

History reveals the tardiness with which medicine in general has progressed, especially as compared with other sciences: it reveals, moreover, that it was only after such men as Galileo, Newton, and Bacon had lived and created an experimental philosophy, and taught us a system of induction of facts to displace conjectural or hypothetical argument, that all sciences of experiment and observation followed the right path of progress and extension.

We have expressed a belief, which it will not be out of place to reiterate, that it is possible, by increase in learning, to raise our profession in public esteem, by enabling, through a proper system of education, its individual members to confer upon the community a larger share of substantial advantage than has hitherto been practicable, and by enabling them to hold a higher intellectual standing. We fancy we hear an indiscreet section of practical men depreciate this proposition of increased intellectual culture, and scoff at the statement that practical utility

can be enhanced in proportion with engagement in appropriate studious pursuits. But the epoch we live in is singularly prolific in facts and arguments to confute these absurd and impotent sneers, which would never have had utterance had their authors possessed the will and ability to attain meritorious distinction. Reflect an instant on the heroes whose noble blood this terrible war has spilt. All that carnage the superficial observer may attribute to the aroused passions of impetuous warriors—to the strong sinew of their herculean arms; but these are agents, secondary to the intellectual workings which, through a long course of training, and the application of the highest branches of science, have been made to influence the movements of each individual soldier to rule the course of each bullet. Even murderous warfare is successful in direct proportion as its operations are guided by well-trained minds.

The first step now is to thoroughly educate the youthful veterinarian, and afford him every facility for acquiring knowledge—to effect which object a strict observance of the rules for the regulation of the Veterinary College is necessary.—*The Field*.

### Miscellaneous.

#### The Dainties of our Ancestors.

Taste, indeed, was more capricious than refined, and the epicure exulting over strong flavours included cetacea among his Friday fare. The whale was eaten by the Saxons; and when men were lucky enough to get it, it appeared at table late in the fifteenth century. In 1246 Henry III. directed the sheriffs of London to purchase one hundred pieces of whale for his table. Whales found on the coast were the perquisites of royalty; they were cut up and sent to the king's kitchen carts. Edward II. gave a reward of twenty shillings to three mariners who had caught a whale near London bridge. Those found on the banks of the Thames were claimed by the Lord Mayor, and added to the civic feast. Pieces of whale were often purchased in the thirteenth century for the table of the Countess of Leicester. England was supplied with this choice dainty by the fishermen of Normandy, who made it an important article of commerce. The Normans had various ways of cooking it; sometimes it was roasted, and brought to the table on a spit; but the usual way is to boil it, and serve it up with peas; epicures looked out for a slice from the tongue or the tail. The grampus, or sea-wolf, was also highly esteemed; but of all the blubber-dainties the porpoise was deemed the most savoury. The Saxons called it sea-swine, and the ecclesiastics of the middle ages *porco marino*. Porpoises were purchased for the table of Henry

III. in 1246 ; and Bishop Swinfield, in the same century, dined off it whenever he had an opportunity ; it was served up at a sumptuous entertainment given to Richard II. at Durham House and at the grand installation of Archbishop Neville, in 1846, four porpoises were on the table. In 1491 the bailiffs of Yarmouth sent a fine porpoise as a present to Lord Oxford, whose favour they were anxious to propitiate, and accompanied it with the message that if they had any other "deyntes to do him a pleasir," they would have sent them also. The worthy bailiffs could find no more savoury present in all the fish-markets in Yarmouth. At the marriage of Henry V., the guests were treated with "roastid perpes," a dish fashionable in the fifteenth century. We find it again at the first course at the coronation of Henry VII. The king was probably fond of this dish, for it was served up at his table on the feast-day of St. George, and my lord cardinal courted his Majesty's favour by sending a fine porpoise to the palace. The cooks not only roasted and boiled it, but made it into pies and pasties; and a learned "Maister Coke" gives a receipt for a delicious "puddying of porpasse," whilst another tells us how to serve it up in fermenty; the wheat was to be seethed in milk, in which finely chopped almonds had been boiled to thicken it; the porpoise was to be dished up smothered in this delicate sauce, which was also coloured with saffron. A poet in 1452 gives directions how to carve "salte porpyesse and seele." In the "Boke of Kerving," mustard is recommended as the best sauce for porpoise, which was to be carved after the manner of venison; and the proper term to employ in asking the carver to help the guests, was to bid him "undertraunche that purpos." This coarse animal was esteemed as food until late in the sixteenth century; it was often on the table of Henry the VIII.; and Wolsey, Somerset, and other lords of the Star Chamber, having in 1509 a snug little official dinner together, feasted sumptuously off a porpoise which cost eight shillings. Even Queen Elizabeth, who was rather choice in her appetite, had porpoise among her Friday diet; and it was sold as food in the market of Newcastle, as late as 1575, from which time it appears to have fallen into disrepute.—*Our English Homes.*

THE DISCOVERIES OF GRAVITATION.—We may further mention that Sir Isaac Newton largely availed himself of Herrox's suggestions to explain the general principles of perturbation, as laid down in the 66th proposition in the first book of the *Principia*. These improvements are so substantial that there is no difficulty in ascertaining the author to whom they are to be assigned. They stand out as a landmark in the history of the science. Taken in connexion with his comments upon the subject of planetary motion, they prove that Horrox holds a prominent position amongst those who have succeeded in

developing that great principle by which creation is held together. Few men are permitted to originate, to confirm, and to promulgate a great discovery. This is usually the work of successive generations. Each master spirit pushes the enterprise a step further; and hence it is often difficult to decide who is fairly entitled to the credit. The final elucidation may be the result of an accumulated experience. The ground is first broken up, then the seed is sown the tender plants are trained, and it grows and thrives, until some one more fortunate than the rest gathers the fruit. So it was with the principle of gravitation, the discovery of which cannot be wholly attributable to one man. It was no doubt, reserved for the transcendent genius of Newton fully to define and to apply it; but the existence of such a power was known to others who came before him; and their ideas respecting it formed part of the data from which he drew his sublime conclusions. Thus Kepler had considerable knowledge of the subject, and many of his conjectures have been substantiated. Dr. Gilbert published similar doctrines in this country, and gave them a more extended application. But Horrox, by his explanation of the perturbative influence of the sun, and by his illustration of celestial and projectile motion, unfolded the theory more completely than any of his predecessors. He seems to have perfectly understood the identity and universality of this unseen power; for he often tells us that the planets in their orbits are affected by it in the same manner as bodies upon the surface of the earth. His accurate views were at length adopted by Newton, and made the foundation of his philosophy.—*Memoir of Jeremiah Horrox*

GREEN, OR ARSENICAL PAPER HANGINGS.—Doctor George Selwyn Morris, of Guisbro', writes, as follows, to the *Leeds Mercury*: "Now that the season is approaching when many persons paper and re-paper their rooms may I be allowed to advise that they should never use green paper, on account of the great quantity of *arsenic* which it contains? From experience, as well as from what I have proved by testing green paper, I am convinced of its pernicious effect upon the system of *some people*. For more than four months my own children were suffering from irritable stomach, irritation of the bowels, loss of appetite, and a deadly paleness of countenance. I was dosing, and doubly dosing, and yet could not conceive the reason why they did not recover, the place being healthy, and the water good which they drank. At last it struck me that the green paper in the room in which they slept had something to do with it. I went up stairs and pulled down all the green paper, and from that day they have never required a single dose of medicine, and now, instead of pale faces, they have rosy cheeks."

**LABELS.**—A cheap and durable label is a great desideratum. There are some good patent labels, but their cost prevents their general use; besides this, many of them must be purchased with the name already on them. If these points are no objection, Bliss' labels possess the other requisites to a considerable degree. A zinc label, written on with prepared ink, is both good and durable. It will last for many years when the ink is good. But the cheapest and most durable label of all is thin sheet lead; it will last an indefinite length of time. It is cut into narrow strips, about three inches long, stamped with a steel die, and rolled around a small branch of the tree to be labeled. It is most convenient to use figures and a memorandum book, in which the names are put down opposite the figures. A wooden label well painted, and written upon while the paint is fresh, will last a considerable time; so also a wooden label, if *wetted*, may be

written upon with Dunn's pencil, and relied upon for two years at least; but wood in any form cannot be regarded as a durable material.—*Horticultur*

**DRY FOOD FOR HOGS.**—A correspondent of the *Country Gentleman* says: "Many hogs are kept comparatively poor by the high dilution of their food. They take in so much water that there is not room for a good supply of nutriment. Hence the reason that those farmers who carefully feed *undiluted* sour milk to their hogs have so much finer animals than those who give them *slop*. The hog has not room for much water; and if food which contains much is fed to him, it makes him big-bellied, but poor." Hogs, as well as all other animals should be allowed all the water they will drink, but it should not be mixed with their food in excessive quantity.

## DUTCH FLOWER ROOTS.

**THE SUBSCRIBERS BEG TO ANNOUNCE** that they have just received their annual importation of Bulbs in good condition—consisting of *Double* and *Single Hyacinths*, \$1.00, \$2.00, and \$3.00 per dozen. A fine assortment of *Tulips*, from 50 cents to \$2.00 per dozen. *Crocus*, 12 to 20 cents per dozen, and at \$1.00 and \$1.50 per 100. *Polyanthus*, *Narcissus*, 12 to

15 cents each.

Descriptive Catalogues furnished gratis on application. They would also call attention to their fine stock of English Hyacinth Bottles, with supports, suitable for growing Hyacinths in winter, and for holding parlour bouquets in summer. (See above cut)

No. 23.

**Agricultural and Veterinary Institution.**

It will be seen from an advertisement on our last page, that a class is about to be formed in this city, for the encouragement among our young farmers of the study of Agriculture in its scientific and practical relations, and of the Veterinary art, in reference to the Anatomy, Physiology, Diseases and their modes of treatment of farm animals. The latter will comprise the history of the different races, and the principles of breeding, with appropriate illustrations. Mr. Smith is familiar with the most approved methods of treating in Europe, being himself a licenciate of the old Veterinary College of Edinburgh, where he attained a high standing, and will study to adapt his instructions to the capacity and special wants of his students, who will have additional opportunities of facilitating their studies by engaging in dissecting and the use of instruments.

In the department of Agriculture, Professor Buckland will receive valuable assistance from several of his colleagues in University College, in Chemistry, Geology, Botany, Entomology, and other branches of Natural History, all of which have important bearings both on the theory and practice of Agriculture. The composition of soils, plants and animals, will be as fully treated of as the time will admit, with descriptions of the most approved implements and machines, and the principles

on which they act. Manures, their composition and modes of action; rotation of crops, and a description of the various products of the farm, and their comparative value; the alteration and construction of Farm Buildings, the laying-out of fields, fencing, road-making, fruit and ornamental planting, will also receive attention.

The chief design of these lectures is to point out to young men actually engaged in farming, who have not had the means or opportunity of making themselves acquainted with the scientific principles on which the agricultural art is based, *the cheapest and readiest way of acquiring this knowledge.* With this great end in view the pupils will be fully instructed how to read and study the best treatises on the various subjects that will come under their consideration, and to form a correct habit of observing, recording, and applying the agricultural phenomena of daily life. As the successful prosecution of agriculture, as a business, greatly depends on a correct and vigilant habit of every-day observation, the opening of the eye and the exercise of the reason and judgment on the changes that occur in nature, and in the markets of commerce, great pains will be taken to develop these qualities in the class, *and to prepare young men to think, study, and observe for themselves.* It being intended to form a class of this character every winter, its studies will as far as possible be made complete in one

term; but in case of students presenting themselves a second time, facilities will be afforded for carrying out their studies and investigations to a wider extent.

In the Veterinary department the instruction will proceed from rudimentary principles to their application in practice; and the main object aimed at is to enable young men to acquire a correct general knowledge of the structure and physiology of the domesticated animals, and of the most approved methods of treating ordinary diseases, an acquisition in itself of no mean practical value. The pecuniary loss to farmers, every year, from a want of this kind and degree of knowledge and skill, is much greater than is generally imagined. Mr. Smith is open, we believe,—to receive *professional* pupils,—such as intend to follow the Veterinary art as a means of livelihood: and one of the chief objects of the Board of Agriculture in originating this movement is the hope of establishing ultimately, in this section of the Province, a regularly organised Veterinary School, in which the various branches will be thoroughly and *professionally* taught by a complete staff of Professors. This, however, must be a work of time. As the live stock of the country has been of late years rapidly increasing, both in amount and quality, and consequently in money value, the proper understanding and treatment of disease is daily becoming a matter of greater moment. Hence the necessity of making a commencement in this direction.

As the introduction to the class, to which we have now drawn attention, will be gratuitous, and no further expense to pupils need be incurred beyond that for board for a week at the most leisure period of the year, it is hoped that a goodly number of young men, desirous of self-improvement, from different sections of the Province, will present themselves on the approaching occasion. Let none keep back from a supposed deficiency in preliminary qualifications; an ordinary English education is all that is really required. The principal requisite is *a desire to learn*. No kind of examination will be required either on entering or leaving the class. But to such as may be disposed to pass an examination in

all the subjects at the end of the term, prizes in books will be awarded in accordance to the proficiency attained. We like the idea of these prizes much; they will tend to stimulate study and a healthful rivalry among the pupils, and those who are successful will take with them into the country some of the best books relating to their pursuits, that will for a long time to come benefit both themselves and neighbors. Such young men will in time become rural missionaries in their respective localities, and infuse around them a desire for knowledge—and agricultural improvement.

### Ice-Houses.

WRITTEN FOR THE AGRICULTURIST.—The best time for building ice-houses being now at hand, and as it is not generally known that with a little additional expense, an ice-house can be constructed so as to answer the double purpose of keeping ice, and preserving milk, butter, &c., I will give your readers a description of one, which I built in the Fall of 1859, with a preserving chamber for this purpose.

Ice can be kept in large quantities during the whole summer season in houses built entirely above ground; but where it is desired to have a preserving chamber, and to insure a sufficiently low degree of temperature to attain good results, it is indispensably necessary that the earth should be banked up to the height of several feet against the outside of the building. In constructing my ice-house, I took the advantage of a convenient and descending spot, sunk a pit fifteen by eighteen, and from 4 to 5 feet deep; walled it up to the height of 9 feet, banked the earth up to the top of the wall all around, except a space for the doorway; upon the wall I put a frame 6 feet high which gives a height inside from the bottom to the comb of the roof of over 20 feet. I put in heavy sills in the bottom, except in a space 4 feet square for the preserving chamber. Upon the sills, I put a floor of two inch oak plank, and on the top of this a floor of one inch pine jointed closely. The floor has a descent of two inches towards the preserving chamber, and it conducts the waste water from the ice to this chamber. I put in an inside frame, and lined it inside; this left a space of six inches between the lining and the wall to fill in with sawdust, and the partition between the ice and preserving chamber is also double, and filled in with sawdust well-packed.

To complete the preserving chamber, I first put in clean sand to the depth of four inches, then paved it with medium burned bricks, they

being preferable to hard, on account of their capacity to absorb and retain a large amount of water. Pains were taken to have the floor exactly level in the one direction, and also very tight, so that all the waste water from the ice shall be conducted to and distributed regularly upon the bricks. This keeps them so constantly cold as to preserve milk, during the hottest season for from thirty-three to thirty-six hours, perfectly sweet, and butter very hard. One valuable feature belonging to this mode of preserving milk and butter is, that during the warmest weather of summer season, when cold sweet milk and butter of a degree of solidity equal to that of the winter season is appreciated as one of our greatest luxuries, we can have it so, from the simple fact that at that particular time the supply of the cold ice water is greatest.

Butter made and kept in this way does not become as soon soft after being brought to the table as that which has been kept in a spring of water, nor do thunderstorms appear to hasten the development of lactic acid. We have noticed no perceptible difference in the length of time which the milk has remained sweet in regard to clear or stormy weather. I have observed at different times, by placing the thermometer within one foot of the bricks in the preserving chamber, that the temperature was about 54 degrees, while it was 95 in the shade outside. The sand underneath the bricks subserves an important purpose, by retaining the water, and supplying it to the bricks by capillary attraction at such time, as there is not a great supply coming from the ice.

The space above the preserving chamber should be opened and unobstructed to the roof, and over the ice there should be good ventilation to the roof, to carry off all the vapour which may arise from the milk.

An ice-house constructed in this manner is one of the best investments for a farmer, for besides securing the luxury of preserving milk and butter cool, vegetables of different kinds may be preserved fresh until a succeeding crop grows. I kept one year's beets good during the following summer; also cabbages. These latter I laid upon the ice, which imparted to them a crispy sweetness, perfectly delightful in the very warm weather of June. Vegetables may also be preserved in this manner by farmers, so as to bring them fresh to the market in early summer.

### Destruction of the Wireworm, &c.

To the Editor of the *Agriculturist*.

SH—As you and your correspondent, AGRICOLA, invite the readers of the *Agriculturist* to give an opinion as to the best mode of destroying the wire-worm, I take the liberty of submitting a few observations, the result of some ex-

perience and long observation on that and some other matters connected with Agriculture. I confess being startled at the communication of your correspondent, as I was not aware of the existence of those destructive pests to the extent Agricola complains of, in any locality of this township. I believe there is at least one infallible remedy for this evil, but unfortunately it is unattainable in most parts of Canada. On the Yorkshire wolds and in Lincolnshire, when old pastures and extensive sheep walks were brought into cultivation, the first, second and perhaps third crops did pretty well, afterwards, the turnips and grain crops were often destroyed, especially on deepish soil, to a considerable extent by the wire-worm and grubs. However the farmers discovered that by giving the land a thorough covering with calcareous marl or lime stone, dug out of pits made in the fields where the evil existed, they effectually got rid of the mischief, and abundant crops of both roots and grain were afterwards a certain result. Some farmers preferred giving the land affected a good dose of quick lime, as the labour was much less than marling or chalking. They also imagined that a profit was sooner realized, in consequence of the quicker fertilizing effects of the lime. But there are but few sections in Canada that will allow of such a practice, and I know of no such a situation in this township that will admit of it. I therefore respectfully suggest to your correspondent a mode of management which, if he thinks worth his while to adopt the principle, will, I sincerely believe, materially lessen, if not rid him altogether of, the grievous evil. I would recommend him to commence by having at least one fifth of his tillage land a naked fallow, and have that thoroughly plowed deep in the preceding fall; as soon as possible after the spring seeding is over and when the land is dry enough, to have the fallow well harrowed, and immediately after thoroughly cultivated as deep as the best implement will allow of, then by a diligent use of harrows and perhaps an iron toothed horse-rake, carefully collect all the weeds, roots of weeds, &c., into heaps and burn them; by so doing an immense number of worms, larvae and ova will be effectually destroyed. When that is accomplished, if from thirty to fifty bushels of quick-lime is carefully distributed over the fallow, and then cross-plowed, harrowed and gone over with a heavy roller to compress and consolidate the ground, thereby retaining the causticity of the lime longer in the land, the lime will be of immense benefit not only by destroying the worms, &c., by virtue of its causticity, but as a fertilizer and by its chemical action on the organic materials of the soil, rendering them more soluble as food for vegetation. It will be well now, to let the land remain three or four weeks undisturbed, then if it should be weedy, the use of the plow or cultivator, or it may be both, will be needed again. After

which, it may be presumed the land will be in proper condition for receiving the dung, prior to ridging up for sowing fall wheat, or, as *Agricola* suggests, allowing a portion to remain for spring wheat.

It is, perhaps, unnecessary to observe that lime and dung should never be applied together, as the fertilizing properties of dung are in a great measure dissipated by the chemical action of quick-lime. The year following, after harvest as soon as other work on the farm will admit of it, it is advisable to plow in the wheat stubble, a portion of which, say half or more, may with propriety be sown with pease in the spring. It is an approved practice to put the pease in with a drill, leaving an interval of twelve or fifteen inches between the rows, to allow of the effectual use of the hoe for the extirpation of thistles and other weeds during the growth of the crop. The remainder of the land, to be appropriated for growing potatoes and other roots. I may observe that the wire-worm and other grubs will occasionally destroy white turnips during the early stage of their growth, but it is a singular fact that those pests will not molest potatoes or Swede turnips (*Ruta Baga*). In my humble opinion grounded on experience of a few years in Canada, the best time for sowing Swede turnips is from the 15th to about the 25th of June. I may say by doing so, I have invariably succeeded in obtaining a crop, and never had to sow the seed a second time in the same season. It is absolutely necessary to have the land in good condition, cleared of all weeds and rubbish, and well pulverized by cultivation. A two rowed seed and manure drill is the best for putting in turnip seed with manure on slight ridges with an interval of about twenty four inches between each,—an excellent composition to drill with the seed, may be prepared of eight bushels of bone dust or half inches, one bushel of salt and eight or nine bushels of ashes to each acre, to be well mixed and screened, to be sufficiently dry when used so as not to interrupt the working of the drill. The fertilizing and alterative properties of this manure, will endure beyond the turnip crop and greatly benefit the succeeding crops. As soon as the plants are in rough leaf, the intervals ought to be well horse-hoed, just before the plants in the rows are thinned out, and kept quite clear of weeds by the horse and hand hoes during the after stages of their growth. The next crop in succession may be spring wheat or barley, with grass seeds of clover and timothy. If the pea and root land has been plowed in the fall, which is the best practice, it will be necessary prior to sowing the grain in the spring, to harrow and then go over it with the cultivator, to make proper channels for the reception of the seed. It perhaps would not be expedient under the circumstance of *Agricola's* farm having the wire-worm, to let it remain longer than one year in

grass; it may then be plowed early in the spring following and sown with oats, which will end the rotation. I am led to believe if your correspondent adopt this or some similar rotation of cropping, he will much mitigate the great evil he complains of, and by diligently weeding thistles and other pernicious weeds, out of all his crops daring their growth, the result of his farming will be both profitable and pleasant to him. To sustain the fertility of the land, it is imperative to collect and take care of all the manure the farm produces. To avoid much of the waste caused by the spring floods washing away the juices of the manure in the barn yard, I deem it advisable to clear the yards as much as possible in February, and pile the dung in tolerably large heaps in the fields where it will be wanted. What liquids flow from the piles during the progress of decomposition are by this plan retained on the land. It occurs to me that the manure would probably benefit the fall wheat most, in the above rotation, and secure a better quality and perhaps more grain, if it could be spread on the sod prior to plowing for the oat crop. It would then become thoroughly incorporated with the soil in the process of fallowing for wheat. Practical and observant agriculturists held that raw manure to a wheat crop encourages too much the growth of straw and makes it more subject to mildew and rust, thus deteriorating the grain. EBORENSIS.

Chinguacousy, Nov. 21st, 1862.

[We are obliged to our correspondent for his valuable contribution, from which *Agricola* and our readers generally may gather useful suggestions. We shall be happy to hear from him again on the results of his agricultural observation and experience.—Ed.]

### Transplanting Trees—Old Notions.

On looking over old recommendations and old practices, it must be admitted that the art of transplanting and managing fruit trees has made a great advancement. It is not beyond the memory of old men, that the recommendation was common to sow oats and plant potatoes in the holes in which newly set trees were placed—the reasons given were the loosening of the soil and shading of the surface. Others held the roots to their places by piling stones upon them. Others again, thought the best thing they could do was to fill the hole with fresh manure, or at least two or three inches of fresh manure directly in contact with the roots. We have seen an orchard of 300 peach trees set out in a clover meadow, without any further care, and where nearly all died the first year. Ten years ago, we inquired of a tree agent of close observation, and who had effected extensive sales of dwarf pears, what proportion of these trees were properly cared for, so as to prove successful and bear crops? His answer was

"not more than one in a hundred—all the rest are thrust out into hard or grass ground, or entirely neglected in culture, or never pruned."

We shall have enough bad treatment; but the number who know what good management is, and who practice it, has increased greatly within the last ten years. Many have learned that oats, potatoes, grass, or any kind of weeds, growing about a young tree, however much they may shade the surface, carry off the moisture from the soil, and exhaust its fertility, many times more rapidly than a simple exposure of the bare and mellow surface of the ground—and that when there cannot be a mulching of this surface by mellow soil, a coating of *dead* vegetable matter is the only thing admissible. Many, after killing whole orchards by placing fresh manure on the roots, have discovered that fine rich mellow earth, is the best thing to be placed in contact.

Agricultural papers have done much towards effecting the improvement that has been made; and nurserymen, who are aware that those who lose trees will not be likely to purchase again, and that the best way to effect sales is for their customers to enjoy fine delicious crops, have accomplished much by their assiduous labors. But in riding through the country, and observing how many young orchards still stand in grass or in neglected fields, we see the continued necessity of urging on the recommendations for better management, and now that the season for autumn transplanting is approaching, we trust that all who desire success, will resolve that the trees they buy these hard times, shall be well set out, and more especially thoroughly cultivated.—*Cultivator*.

#### EXPERIMENT TRIED WITH DISEASED POTATOES.

On taking up a crop of potatoes in the first week of October last year (1861, I found that three parts of them were very badly affected with disease—indeed so much so, that they were too bad even for the food of the pigs. I was induced to try with them an experiment on a small scale, which was done as follows:—On the day following that on which they were dug, I had a piece of ground (60 feet wide by 112 feet long) dug up to the depth of 14 inches; the drills were opened at a distance of 2 feet drill from drill; then the diseased tubers were planted whole, at a distance of 3 inches, set from set, in the drill; a good dusting of newly slacked lime was spread over all the sets in each drill; and they were then covered over with soil to the depth of 7 inches. Nothing more was done to said piece of ground until this spring, when, to my agreeable surprise, the plants made their appearance above the surface, with scarcely a blank over the whole piece. The ground was then forked over between the drills to the depth of 10 inches, so as to loosen thoroughly the soil, and nothing more was done beyond once drawing a little soil to the plants,

and keeping the ground clear of weeds, until the 17th of last July, on which day I commenced taking up the potatoes for use, and, to my astonishment, I found a crop such as I never before have witnessed since the disease first attacked potatoes in this country; for they not only were most prolific, but of an unusually large size, and up to the present date (August 26) I have not found one tuber affected by the disease.—JOHN DAVIES, Gardner to Sir C. H. Coote Ballyfin House, Mountrath, Queen's County.—*Field*.

#### On the Construction of Piggeries.

We take the following useful suggestions on the best methods of constructing piggeries from a treatise on the Hog, recently published by C. M. Saxon, Barker, & Co., New York. Too little attention is paid to these matters by farmers in general. No animal pays better for good feeding and proper care than the pig:—

There are few things more conducive to the thriving and well-being of swine than airy, spacious, well-constructed styes, and, above all, cleanliness. The old prejudices—that any place was good enough to keep a pig in, and that filth and pig-styes were synonymous terms—are now passed away, and the necessity of attention to this branch of porcine economy generally recognized.

Formerly swine were too often housed in damp, dirty, close, imperfectly built sheds, this was an error, and a fruitful source of disease, and of unthrifty animals.

In large establishments where numerous pigs are kept, there should be divisions appropriated to all the different kind of pigs; the males, the breeding sows, the newly weaned, and the fattening pigs should all be kept separate; and it were as well that in the divisions appropriated to the second and last of these four classes, there should be a distinct apartment for each animal, all opening into a yard or enclosure of limited extent. As pigs require warmth, these buildings should face the south, and be kept weather-tight and well drained. Good ventilation is also important, for it is needless to expect animals to make good flesh and retain their health unless they have a sufficiency of pure air. The blood requires it to give it vitality and free it from impurities, as much as the stomach requires wholesome and strengthening food, and when it has it not, becomes vitiated, and impairs all the animal functions.

"The blood, the fountain whence the spirits flow,  
The generous stream that waters every part,  
The motion, vigor, and warm life conveys,  
To every moving, breathing particle."

becomes contaminated by those aerial poisons given out by the decaying vegetable matter, rotten or damp litter, accumulations of dung, and animal exhalations engendered by ill-ventilated styes.—These noxious gases are inhaled by the skin, until they enter the circulation, and impair its vivifying fluid. It is by the action of the atmospheric air that venous blood is converted into arterial, freed from all its impurities, and rendered fit to sustain all the vital functions; hence it must be at once evident that if this important agent is in the first place contaminated, its action must be impaired and its effects empoisoned. Besides, bad smells and exhalations injure the flavor of the meat.

Damp and cold floors should also be guarded against, as they tend to induce cramp and diarrhoea; and the roof so contrived as to carry off the wet from the pigs.

The walls of a well-constructed sty should be of solid masonry; the roof sloping, and furnished with spouts to carry off the rain? and floors either slightly inclined toward a gutter made to carry off the rain, or else raised from the ground on beams or joists, and perforated so that all urine and moisture shall drain off. Bricks and tiles are much used for the flooring of styes, but are objectionable, because, however well covered with litter, they still strike cold; wood is far superior in this respect; as well as because it admits of those clefts or perforations being made which we have just recommended, and which not only serve to drain off all moisture, but admit fresh air as well. The value of the litter and dung as manure, must always be borne in mind, and all things so arranged that none of it shall be wasted.

The door of each sty ought to be so hung that it will open inwards or outwards, so as to give the animals free ingress and egress; and to do this it should be hung across from side to side, and the animal push it up to effect its entry or exit: for if it were hung in the usual way it would derange the litter every time it opened inwards, and be very liable to hitch. If it is not intended that the pigs shall leave their sty, there should be an upper and lower door, the former of which should always be left open when the weather is warm and dry, while the latter will serve to confine the animal.

There should also be windows or slides which can be opened or closed at will, to give admission to the fresh air, or exclude rain or cold.

Mr. Henderson's descriptions of the styes is more lucid and practical than mere vague directions, we will therefore give it in his own words:—"The plan which I recommend is as follows. Have a house thirty feet by fifteen, with four doors all opening outwards, and three partition walls through the house, viz., a wall between each of the doors, dividing the house into four compartments. The two middle ones I use for eating-rooms, and the other for sleeping-apartments, having an inner door between each eating and sleeping-apartments.

"The following is the most convenient manger for their food. Let it be as long as the house is wide, and fixed against the middle wall; in form similar to a horse manger, but not so deep, and must be divided into twelve divisions by partition bands four feet in length or height, and a little broader than the manger is wide; thus a number will feed as well and as quietly together as two or three. Before every meal the trough should be well washed and the place swept, and once in the day a little fresh litter placed in the sleeping chambers. Each of these sleeping, and eating rooms may be temporarily divided into two, if necessary. The sleeping rooms should be dark, as animals fatten much more rapidly when they lie down and sleep after each meal than they do when they wander about. There should be a square yard to each piggery; well paved and drained, as should the styes also be; and where it is possible, an enclosure or a small piece of ground adjoining is exceedingly useful."

Those who have space to admit of it will find it advantageous to have five apartments instead of four, and in the fifth or central one to have a boiler to prepare the food, and chests and lockers to contain the various stores."

Parkinson advises that in the yard or enclosure before every piggery should be a "rubbing post or what is still more beneficial, two posts having a pole between them similar to a horse's leaping bar, but not revolving; this pole should be raised or let down to the height of the pigs, as the rubbing of the animals against it causes a freer circulation of blood, the same as the flesh-brush does to human bodies."

In all large establishments there should be a proper apparatus for cooking, mixing, and preserving the food. For this a boiler and steamer will be requisite, and some two or three tanks which may be made of bricks plastered over on the interior to prevent leakage, and fixed in the ground. Wherever it can be managed, troughs should be so situated that they can be filled and cleaned from the exterior without interfering with or disturbing the animals at all, and for this purpose, the following very simple contrivance has been recommended: "Having a flap or door with swinging hinges made to hang horizontally over the trough, so that it can be moved to and fro, and alternately be fastened by a bolt to the inside and outside of a manger. When the hogs have fed sufficiently, the door is swung inwards and fastened, and so remains until feeding-time, when the trough is cleaned and refilled without any trouble, and the flap drawn back and the animals admitted to their food." Some persons cover the trough with a lid having as many holes in it as there are pigs to eat from it. This is by no means a bad plan, for then each pig selects his own hole and eats away without interfering with or incommoding his neighbor.

We are indebted to the kindness of a friend

for the following account of the Royal piggery, at the Home Farm at Windsor. It consists of slated sheds, of sufficient length and breadth to contain about two dozen styes, of somewhat larger dimensions than ordinary pig-styes, and arranged in two rows with a broad walk between them, from which the spectator looks into the styes on the right and left of him. Each sty has an in-door and an out-door apartment, the former having a wooden coverlid to it, going upon hinges like the lid of a corn-bin, instead of a roof, which may be raised to any height in hot or close weather, so as to admit any influx of air required, or even to be thrown back if necessary. The styes are paved with brick both within and without doors, and their floors slightly declivitous.

The following is a description of a piggery at Lascoed Pont Senny, planned and executed by Mr. J. Donaldson, land steward to A. M. Storley, Esq., Brecon, South Wales:—This piggery is constructed for the purpose of breeding and feeding on a large scale to suit a farm of six hundred acres of turnip soil in an inland situation, where convenient markets render easy both the disposal of fat and lean stock. There are seven styes at the end of the steaming house which accommodate a boar and six brood sows, which are calculated to produce yearly one hundred pigs, sixty of which will be fattened from September to April in fifteen styes, placed in two parallel rows, and made to contain two hogs in each apartment. The rest are sold as stores. The yearly rental is from £200 to £250 according to the prices of the produce. The steam food consists of potatoes and meal, with grain to finish, and is conveyed to the styes along a paved road or path, in a small four-wheeled waggon. The steamer also cooks potatoes for the working horses, and chaff for milch cows, and thus applies the original cost to several purposes, and fully employs a man. The store pigs are fed in summer with clover and vetches, and in winter with roots either raw or steamed. Water is brought to the steaming-house in a pipe from the farm yards, which are all supplied by ball-cocks from elevated casks fed by a forcing pump. A dipe underneath conveys the water from the potato-washer to the pond in the store-yard, where it passes to the yard, and then meeting with the collected moisture of the whole area of the piggery, falls through an iron grate into a paved culvert, and is conveyed to the manure pit, to which the liquid of the farmery is collected and brought by a drain; along the sides of the road are sheds opening into the store-yard. The cost of erecting a piggery like this will vary from £80 to £100, according to the price of labor and materials, and to whether the roofs be tiled or slated. The steaming-house has an upper floor to serve as a store-house for grain, meal, roots, &c.

The piggery should always be built as near to

that part of the establishment from which the chief part of provision is to come as possible, as much labour will thus be saved. If the dairy is to supply this, let it be as near as may be to that building; or if it is to come from a brewery or distillery, then let it be near to them.

Care must also be taken to preserve the dung and urine, and some place fixed in which these matters can be stored for manure. Wherever the swine are regularly and well managed, this will not be difficult, for the animals will always, if they can, lay their dung at a distance from the place where they sleep or feed. A small paved yard, somewhat sloping, and with a gutter to serve as a receptacle, will best answer the purpose, and thence it can be daily removed to the proper heap or tank.

We have been told of a gentleman who keeps only a few pigs for his own use, and has a double sty for them, by which means he is enabled to keep them exceedingly clean and sweet. Every morning the pigs are changed from one into the other so that each sty remains unoccupied for four and twenty hours, during which time it is thoroughly cleaned out, and of course becomes well aired, and free from all unpleasant smell. And well do we remember the pleasure with which we used to view the pigs and styes of an old friend of ours now no more. A door leading out of his beautiful flower-garden brought us to those equally well-tended objects of his pride. The styes are always kept whitened on the inside; the sloping floor carried off all moisture to a deep gutter running between the sty and the square-paved yard, each of which inclined towards it: a trough ever stood with water clear as crystal for them to drink, and the animals themselves were, by washing, currying, and perfect cleanliness about them, as neat and sleek as a lady's lap dog. They were, in fact, pet pigs. Nor are we without pleasurable reminiscences of delicate spare ribs, loins, and legs of pork, and delicious sucking pigs.

Washings, combings, and brushings, are valuable adjuncts in the treatment of swine; the energies of the skin are thus roused and the pores opened, consequently the healthful functions are aided, and that inertness so likely to be engendered by the lazy life of a fattening pig counteracted. We cannot close this chapter without quoting the following account of the mode of keeping pigs in Mexico:

"Fine breeds of these useful animals are kept by many persons of wealth, as an article of trade, in the city of Mexico; and the care and attention paid to their cleanliness and comfort so far exceed any thing I have seen elsewhere, that a short account may be useful by furnishing hints to our farmers, brewers, distillers, &c., by whom numbers of these valuable animals could be and are conveniently kept. The premises where the business is carried on are extensive, consisting in general of good dwelling-houses, with a shop, slaughter-house, and places for singin; the

pigs, large bowls for rendering the lard, salting and drying-rooms, and lard-rooms, with wooden bins for containing the rendered fat, which is an article of great consumption in Spanish cookery, being used as a substitute for butter. There is a soap manufactory, in which the offal fat is manufactured, and apartments where the blood is made into a kind of black-pudding, and sold to the poor. Behind all these are the styes for the hogs, generally from eight hundred to one thousand in number, which occupy a considerable range of well-built sheds about thirty feet deep, with roofs descending very low, and having the entrance through low arches, before which is an open space the whole length of the yard, and about twenty-four feet wide, in the centre of which is a kind of aqueduct built of stone, and filled with clear water from a well at the end of the premises. The hogs can only put their noses into this water through holes in the wall, which prevents their dirtying it, as it passes through the whole division of the yard. This is the only liquid given them, and their food is maize or Indian corn, slightly moistened, and scattered at stated hours on the ground, which in the yard, as well as the place where they sleep, is kept perfectly dry and clean. They are attended by Indians with every possible care. There is a cold bath on the premises, which they are obliged frequently to use, as cleanliness is considered essential to their acquiring that enormous load of fat from which the principal profit is derived. Their ease and comfort seem also in every respect to be studiously attended to; and the occupation of two Indian lads will cause a smile on the countenances of my musical readers when they are informed that they are employed from morning till night in settling any disputes or little bickerings that may arise among the happy inhabitants of this community, either in respect to rank or condition, and in singing them to sleep. The boys are chosen for the strength of their lungs, and their taste and judgment in delighting the ears and lulling the senses of this amiable harmonic society; they succeed each other in chanting during the whole day, to the great delight and gratification of their bristly audience, who seem fully to appreciate the merit of the performers."

### Training Colts Young for Special Objects.

The great importance of considerable regular exercise in the development of strength, growth, health, and their cognates, is, in one way or another pretty generally recognized and conceded. An animal cannot live without breathing; cannot breathe without a natural supply of air; and cannot get a full natural supply of air without ample exercise or locomotion. The extent to which an animal breathes depends, beyond a limited point, absolutely upon his exerting his loco-

five organs. In brief, breathing has been made by the author of nature to *depend*, in a large degree, upon exercise as a cause, basis, and motive force. The circulation of the blood generally, as well as the whole process of nutrition, depends largely upon the extent in which the motive force of exercise is brought into play. A thorough and able thinker and writer says, "Though not the sole cause of the circulation of the blood, yet it (exercise) is an indispensable condition. The contracting muscles everywhere impel the blood along its course, and without the aid of conditions established by exercise, the motion of the fluids of the body flags and stops; the outlets of the body become choked, and waste matters are not disposed of; affinity of the blood for oxygen declines, and the vital fluid remains unpurified; the stomach no longer digests food, because it is not taken away from that organ; the extremities lose their healthful temperature," &c., &c. Such are some of the reasons why circulation, nutrition, and general growth all depend upon exercise in so great a degree. I quote further very briefly. Exercise "not only determines the *amount* of food and oxygen required by the system, but is absolutely necessary in the *disposition* there made of them." Thus the formation of the muscular system of all animals most certainly depends upon exercise; and the muscular parts and powers of the horse more so than those of any other domesticated animal, because of the greater natural activity which his structure is fitted for and his health requires. Very many illustrations of the influence of exercise might be cited, as the large muscular parts and powers of negroes and other laboring men, as compared with the slender limbs and little strength of those who make their growth in in-door or inactive life. The arm of the smith and sailor show its effects on particular limbs or members, when those are used or exercised more than other parts of the system, though this has been so often referred to as to be generally admitted.

What I wish on this occasion is to show the application of the principle to a new purpose, viz., to the training of colts, and the maturing of horses for special objects or purposes. At present, so far as I am aware, nothing more than inherited qualities, and good *general* muscular training *after* colts are old enough for work, comprise about all that is depended on to insure excellence of power for any particular purpose or order of labor, as trotting, carrying, or drawing. The English race-horse, and the American trotting-horse are very regularly exercised; walked, trotted, or cantered, or all in succession, as the case may seem to require. This course strengthens the muscular system and maintains the *general* vigor or muscular power as a matter of natural consequence.

But has the principle of increasing the size and power of the muscles of any important part of the body by special treatment or exercise of

such part and for a specific object ever been tried? I have heard of no experiment of the kind so far, yet I perceive no reason why the principle is not sound; why the idea cannot be made practical. Every one has been informed of the enormous increase in the muscular power of Dr. Windship resulting from special training, as is equally well known with facts before alluded to.

Though there be an increase of general muscular growth and power, in animals and men that take much exercise, over that in those who take little, still there is a limit in the vital power of any particular individual to the extent of general increase of muscular power. If all parts of the system are increased in size and power in a colt or a lad, from full general exercise, it seems to follow that if some part is exercised more than another, but not beyond its power of recuperation, that part will receive the most blood and the greatest degree of enlargement in size and increase of strength. This is illustrated by the instances already cited, and the causes of it are well defined in the quotation.

Now suppose the owner of a good brood mare, wishes to raise excellent saddle horses or horses that can draw unusual weights or given weight, at high speed in proportion to their own inches; why cannot this be done? I not only do not believe it not impracticable, but the contrary. Windship commences with lifting 500lbs. and increases his muscular power till he lifts a ton (I have not the information as to how much he can lift at present.) This is accomplished after he has *done growing*, after his muscular system generally is fully matured. If he had commenced special training while yet growing it is probable that his muscular growth and power would have been still more extraordinary in proportion, or nearly in ratio to the muscular means that induced it, up to the limits of total constitutional power. I am amongst those who favor training colts from the earliest possible time till maturity, and as men become great runners, walkers, lifters, etc., etc., by special training, I see not why the colt cannot have a strong back and the other accessories to great carrying power, or a good saddle horse, from similar agencies. Suppose a halter-broken colt, as soon as weaned; then commence with him in carrying light loads, very gradually increased till he has made his full growth, or till he is six years old. Is it not highly probable by this sort of training—the general management being good—he will be able to carry *double* the weight by this time that he could have carried as easily with such training as is generally given? The same course might be adopted as to draft horses, either with heavy weights at a low gait, or light weights with high speed; but not as to both with the same animal, if a specific success is aimed at.

Neither can the natural adaptation of any animal for any given special work be disregarded in assigning him to a different sort of work and ac-

tion. Natural fitness, as well as special discipline, is requisite to success. All parts of the process—as all the wheels of a machine—must support one another with proportional dependence and power.

The principle upon which vital power acts in supplying unusual force, in such instances as we are contemplating, appears to be somewhat like this: Nature in a general way, has the power of self-adjustment, is self-protecting. If you use your legs, for instance, more than other members, they will be worn more by the attrition and friction resulting to all substances from motion or matter in contact, and suffer greater exhaustion of their substance thus worn off. To readjust this loss the vital power impels more blood to the part subject to extra motion and wear, and the flow of blood increasing in proportion to the increase of action and exhaustion, the part—legs, arms, back, or shoulders—is replenished and enlarged by a steady augmentation of substance or nutrition deposited from the increase of blood, till a large proportional increase of size and strength is the result—of specific increase of exercise as the prime original cause; and this course of nutritive action continues till no farther supply of blood can be spared from the general system to any particular part in excess without danger of exhausting or impairing the general health and strength.

The principle is much the same as training a tree in some particular form, by causing the sap to flow in the desired direction—in certain branches more than any other; both sap and blood being subject to the control of vital organizing force, naturally opposed to and inconsistent with general chemical combination. And, as a simple practical question, I perceive no reason why the leading muscles engaged in drawing, carrying, &c., in colts, may not be increased in size and power as readily, and by similar means, in the back, shoulders, &c., as in the human arms or pedal members. It appears to me a practicable project, and if those who have the leisure and inclination and perseverance will give the idea a proper trial, I am satisfied that there need be no disappointment, but that the capacity of the horse will prove capable of special as well as general training and application, to an extent not by many anticipated.—*American Stock Journal*.

## Horticultural.

### Thinning of Fruits.

The following extract from the address of the President of the Pomological Society at its recent meeting in Boston, Mass, contains much that is of practical value to all cultivators of fruit:

One lesson which experience has taught us is the importance of thinning the fruit, especially

of apples and pears. This branch of Pomology has received comparatively little attention. There is a limit to the capabilities of all created things. If you tax the enemies of an animal too severely for a long time, the result will be premature age and decay. Subject any vegetable or mineral substance to too great pressure, and you destroy its power of cohesion. So if you permit a tree to bear beyond its strength, you injure its fruit, retard its growth, and shorten its life. All have observed that superfecundity one year produces barrenness the next. Hence we hear among our farmers and gardeners of what they term the bearing year. They invariably designate the Baldwin apple as a tree that bears on alternate years. But is not the cause of this alternation found in the fact, that the abundant crop of the bearing year exhausts the energies of the tree, and absorbs the pabulum so as not to leave sufficient aliment for the formation of fruit spurs for the succeeding year? Many varieties have a tendency to overbearing, especially those which produce their fruit in clusters. Nature herself teaches us the remedy for this evil, and a superabundance of blossom is generally followed by a profuse falling of the embryo fruit. When and where this dropping is not sufficient to prevent overbearing, we should resort to the process of relieving the tree of a portion of its fruit.

The organism which carries on healthful development, in order to repeat its cycle of functions from year to year, cannot be overworked without time for recuperation. Whatever of nutrition goes to the support of useless branches, or a redundancy of fruit, abstracts that strength from the tree which would otherwise be appropriated to the perfection of the crop, and the development of the spurs which would bear fruit the next year. One of the best cultivators in the vicinity of Boston has reduced this theory to practice, with the happiest effect, in the cultivation of the pear. His system allows no useless wood, nor more fruit spurs, and no more fruit than the tree can properly sustain. As a consequence, it produces every year superior fruit which commands the highest price. Some have doubted whether this practice can be made remunerative, except in its application to the finer fruits. But another cultivator, who raises, an annual crop of the best apples, assures us that the secret of his success is the thinning of the fruit, and he has no doubt of the economy of the practice. No good farmer doubts the necessity of thinning his root crops, no *vigneron* the propriety of thinning his grapes. Analogy of cultivation, therefore, justifies the practice, and I entertain no question of its great importance.

Light, air, moisture, are essential to the production of vegetable products, and especially of fine fruits. Who has not observed that the best specimens of fruits on a tree are ordinarily those which are most exposed to these elements?

Who does not select the full sized ruddy fruit, which has free communion with light, heat, and air, in preference to the half fed specimen which has shared its own proper nourishment with five or six crowded rivals on the same spur?

An experienced English cultivator says:—"The bending of branches of trees by an over crop of fruit is most injurious, for the pores of the woody stalk are strained on the one side of the bend, and compressed on the other; hence the requisite nourishment flows being partially shut up, the growth of the fruit is retarded in proportion to the straining and compression of the stalk." This is illustrated in the overbearing of some varieties, which from a redundancy of fruit, without the process of early and thorough thinning, seldom produce good specimens, and in a few years become stunted and unhealthy trees. The overbearing of a tree is as much a tax upon its energies and constitution, as is the exhaustion of a field by excessive crops of the same kind year after year, without a return of nutritive materials. Inexhaustible fertility is a chimera of the imagination. Sooner or later, the richest soil will require a restoration of what has been abstracted by vegetation. However fertile at first, the constant overcropping of the soil is a reduction of the elements on which health and fruitfulness depend. This great principle of sustenance and reciprocal relations runs through the whole mass of life, of mind, and of matter.

"One cry with never ceasing sound,  
Circles Creation's ample round."

Intimately connected with this process of thinning, is the time when the work should be executed. It should not be done before we can distinguish the choicest specimens in a cluster of fruit, nor delayed so long as to waste the energies of the tree. This practice, judiciously followed, will supersede the necessity of staying up the branches, will prevent injury to the tree by their breaking, and will prove decidedly economical.

"Associated with the thinning of fruits is the expediency of gathering a part of the crop as soon as it approaches maturity. The remaining specimens will thereby be much increased in size and excellence. The fruit of a tree does not all come to maturity at the same time, hence this successional gathering will turn the crop to the highest practical account, and will keep the productive energies of the tree in a healthful and profitable condition."

### The Ever-Blooming Rose.

If there is perfection in the vegetable kingdom, it is the Ever-blooming Rose. Its varieties are now so numerous, their colors so various, and natures so different, that they are arranged into five distinct classes.—Some can be grown in all climates and altitudes, and upon nearly

all kinds of soil. They are fit to make a diversified garden of themselves; growing as dwarf bushes, as tall stately plants, and clothing arbors, trellis-work, dead fences, &c., and even making hedges to fence in and shelter the garden. They are the monarchs of the flower bed, and reign triumphantly glorious over all other flowers; and blessed are they who possess the means, the liberality, and fine taste, to purchase all kinds, and the space to grow them in perfection.

The *Hybrid Perpetuals* or *Remontantes*, are generally of a stately robust growth; thrive equally well upon heavy and light loams, and withstand a northern winter without protection.

The *Bourbons* are next in hardiness, and do best upon loamy soils, yet a slight covering of straw tied around them in winter north of New York, is of advantage to them.

The *Bengal*, *Chinese* or *Daily*, is next in hardiness, thrives both in loamy and sandy soils, and is preserved better by having a little straw tied about them north of Philadelphia.

*Noisette* is of the same hardiness as *Bengal*, and thrives upon the same kind of soils. The varieties are nearly all of a rampant growth; useful for training upon fences, ends of buildings, arbors, trellis-work, pillars, verandah frames, &c. The flowers, are generally small, double, and produced in clusters of twenty and upwards.

The *Tea scented* is generally of dwarf growth, profuse in bloom, and of the most delightful fragrance, which is diffused a great distance. They are less hardy than the other class, and need a covering of straw in winter north of Baltimore. They thrive best upon light loams and sandy loams, and will flourish in sandy soils. They grow to most perfection out of doors south of Maryland, and are the best for pot culture.

All the varieties of the five classes can be grown in the most northern climate by digging them up and potting them in the fall, and keeping them in cold frames or pits half sunk and half banked up, and with glass sashes, and covered with mats in very cold weather, shading them from bright sun in the winter time. As hundreds are yearly putting up cheap glass structures in which to grow foreign grapes, they are the best places to winter roses that cannot stand the severity of winter, as the grapevines are dormant in winter, and the roses could not be in their way, and they get the full light. With these advantages, people in northern latitudes can grow all kinds, and well will they be rewarded for their care.

What is a garden without a rose! As it lasts many years and takes deep root in the ground, the soil before planting should be stirred two feet deep and finely pulverized and enriched with short manures throughout. The black surface scrapings in woods, which is leaf mold, is the best manure for all kinds of roses.—*W. Elder, in Gardener's Monthly.*

## Grape Vines.

Those vines which need protection should soon be taken down and covered with leaves, straw, or if the drainage is sufficiently good, with earth. The covering need not be thick, as a slight shelter will keep off the frost. Cut away most of the wood you design to have pruned, before covering. If the vines are left exposed, do not prune, as the winter may kill them, so that your pruning would take a different course in the spring. A subscriber who has purchased vines for the *Isabella*, which turn out to be the pigeon grape, wishes to know how and when to bud. It should be done as soon as the sap starts in spring. Cut an eye about three inches in length, having attached as much wood as you can get with it; at each end of the eye cut off about a quarter of an inch of the upper bark, making the ends very thin. Next cut out neatly a notch in the bark of the vine you wish to bud, and fit in the eye to the place exactly as possible. Bind it about firmly with some soft bandage, as of matting, and clay it, taking care not to cover the eye. Bind it about with moss and keep it moist until the bud begins to swell. As your vine throws out young shoots, pinch them off above the bud to give it more strength, and after a while keep the branch you have budded entirely pruned down about the bed.—*Jour. of Agriculture.*

## MODE AND TIME OF PLANTING GRAPE VINES.

—Geo. W. Campbell, of Delaware Grape notoriety, makes the following remarks in his circular: I have found little difference in the growth of vines, whether planted in Fall or Spring. When planted in the Fall, and slightly protected during the first winter, an early start, and usually a more vigorous growth may be expected, than from vines transplanted in Spring. A somewhat elevated situation, and a deep, pervious soil, moderately rich, is best. A calcareous clay loam, well underdrained, will produce good, healthy vines and fruit, and if abounding somewhat with gravel or pebbles, so much the better. If lime does not exist naturally in the soil, it should be pretty freely supplied; and if the soil is poor, enrich it with any well decomposed manure at hand. Fresh, or partially decomposed manure induces unhealthy growth, and disposes vines to mildew. Low situations, where water can settle and stagnate about the roots, will not answer. Where immediate fruiting of young vines is desired, permit but one cane to grow; stop, or pinch off all laterals at one joint from the main stem; keep the vine tied upright, and at the height of four or five feet pinch off the leading shoot. This course will strengthen the lower buds, and often give fruit the year after planting.

## Veterinary Department.

(Conducted by A. Smith, V. S.)

### Variola Ovina, or Small Pox in Sheep.

This singular disease has broken out in several extensive flocks in the north and west of England, attended by heavy losses, and from the latest accounts considerable anxiety was felt by the flockmasters both of Great Britain and Ireland lest its ravages should extend northward. The following communication of a Veterinary Surgeon in Dublin, published in a recent number of the *Irish Farmer's Gazette* will be read with interest:

SIR,—This disease, now prevalent in some parts of England, and designated by the French, *Clavelle*, is an acute inflammation of the tegumentary investment of the body, associated with fever of a highly contagious nature. Pathologists divide it into distinct, confluent, natural, and inoculated, the two former referring to the separation or non-separation of the enlargements or papulæ which appear on the skin of the affected animal; the two latter, to the causes of the disease, whether they be that of simple exposure to the affection, natural, or direct introduction of the ovine virus into the system inoculated: of these four varieties, the confluent form is more fatal than the distinct, and the natural than the inoculated.

Many diseases affecting the lower animals are capable of remaining dormant for sometime after their respective poisons have been received into the system. This period, though varying, is technically termed the period of incubation, and is influenced by circumstances of an external nature, such as the temperature of the surrounding air, freedom from or presence of other diseases, temperament of the animal, &c., causes which either hasten or delay the eruption.

Hurtel d'Arboval, in his treatise on the subject, remarks that in warm weather the malady will show itself in ten or twelve days, but remain dormant for double that time when the temperature is low. In experiments conducted at the Royal Veterinary College, London, the period varied from seven to thirteen days. The incubative stage having expired, features characteristic of the malady appear in the form of papulæ or nodules having a florid appearance, deeply imbedded in the skin, generally located on the inner side of the cheeks, arms, and lips, which either coalesce or remain separate, constituting confluent small pox in the former case, distinct in the latter. In about three days the papulæ become converted into vesicles by effusion underneath the outer skin, or dermis, of a transparent fluid. The fluid contains the virus

of the ovine pox. The contents of the vesicles become consecutively opaline, turbid, less serous, and ultimately converted into dry, hard crusts which fall and leave depressions of various depths, to be filled up by a process of healing termed granulation. In addition to the local changes just described, the animal gives constitutional evidence of this disease, by separating itself from the flock, mucous discharge from the nostrils, head and ears pendent, eye-lids swollen, with a flow of tears down the face, respiration hurried, pulse quick and indistinct, approaching dissolution.

Although the introduction of sheep pox into Ireland would be a calamity generally to be lamented (difficult to prevent, unless the importation of English sheep be suspended for a time), and one that would most assuredly result in the death of thousands of our sheep, the profession have furnished themselves with a weapon, namely, ovination or inoculation, which in the hands of the scientific veterinarian, has been, and would again be, the means of precluding the natural disease by the artificial, and thus deprive the former of its mortal potency. This practice was proposed by Chabette, in 1762, by Bourgelat, in 1765, by Coste, 1795, and is annually resorted to in France, Austria, Prussia, and Italy. In a treatise by Hurtel d'Arboval it is set forth that of 32,317 inoculated sheep, 32,121 took the artificial disease and only 270 died. In order to test its prophylactic power, 7,697 of the successfully inoculated sheep were exposed to the influence of contagion, and not one suffered a second time; but it is not necessary to travel to the continent for statistical information.

Professor Simonds, in his lectures, states that he found the mortality of the natural disease to be from 50 to 75 and even 90 per cent., whereas the number of deaths attending ovination, when properly performed, averaged five, but rarely reached ten per cent. Yet, much as may be said in favour of the operation, one objection exists. The inoculated and natural disease are equally contagious, hence the absolute necessity, when ovation is practised, of so far isolating the affected animals as to prevent even indirect contact with the healthy.

The most benign case of distinct small pox in the vesicular stage having been selected, the operator chooses a solitary vesicle having clear aqueous contents, and places the point of instrument (which is a kind of needle made for the purpose) barely far enough into the vesicle to moisten the top. This may be preserved for purposes of inoculation for several weeks. If necessary, the operator may at once insert point of same needle between the cuticle, or outer skin, and dermis or true skin, avoiding the production of the smallest drop of blood. Bear in mind that the incision cannot be too minute, and the needle cannot contain too little fluid. The parts operated on are, the under surface of the teat,

which is the most advantageous, inner part of the thighs, postero inferior part of the abdomen, and lateral parts of the sternum. Evidence of successful inoculation will be given in about three days, by a speck, remarkable for the intensity of its redness, which enlarges simultaneously with the increase of inflammation till the eighth day. Tenth shows unibilication of the centre; thirteenth, blanched appearance, due to the elevation of the cuticle from the true skin, and effusion underneath of a transparent fluid; eighteenth, a brown scab, which falls, leaving a chasm to be filled up by a process of reparation, termed granulation. As it sometimes happens that the vesicle of inoculation is the only one which appears, for purposes of ovination the fluid therein contained may be used, and reliance placed on its reproductive potency.

In order to render the virus of sheep pox milder in its constitutional effects, it has been proposed to pass it through the systems of other animals; but all such attempts have signally failed. Sheep pox cannot be transmitted to the ox, goat, or human subject, neither shall the small pox of man or the analogous vaccine disease of the cow produce a like affection in the sheep. Purification, however, can be effected by causing it to travel successively through the systems of several sheep; lymph so procured degenerates a disease which goes through its several stages more regularly, renders the constitutional disturbance and local ulceration less; hence the losses are fewer, and the management of the existing disease easier. Having operated on a flock of healthy sheep, they should be divided into several lots, to prevent crowding (which is apt to induce a malignant form of the disease), provided with well ventilated apartments, supplied frequently with fresh water, and allowed good, nitrogenous food. In the majority of instances the foregoing cursory remarks (which are merely intended to convey to the reader a rough notion of the disease in some of its forms) will, I think, be found sufficient, if properly carried out, to ensure more than average success.—Yours, &c., ANDREW GANLY, V S., *Usher's Quay Dublin.*

## Transactions.

### Prize List, Provincial Exhibition.

The following is the corrected list of the prizes awarded at the Seventeenth Annual Exhibition of the Agricultural Association, held at Toronto, September 23 to 26, 1862:

#### CLASS I.—BLOOD HORSES—(31 Entries.)

*Judges.*—E. Wilmot, Kingston; G. Bennett, Cobourg; Geo. Robson, London; Capt. Tyrwhitt, Bradford.

Best thorough-bred stallion, Thomas Downing, Oshawa, "Young Sir Tatton," \$40; 2nd do, Ed. Arkland, Oshawa, "Kennett," \$25; 3rd do, Geo Cooper, Toronto, "Highflyer," \$12.

Best 3 years old stallion, Thomas Downing, Oshawa, "Imperator," subject to proof of being thorough-bred, \$22; 2nd do, Simon P. Dumond, Scarboro, "Wagoner Eclipse," subject to proof of being thorough bred, \$14; 3rd do, Geo. G. Grange, Guelph, "Pluto," \$7.

Best 2 years old stallion, George Palmer, Guelph, subject to proof of pure breeding, \$14.

Best Yearling colt, John Dew, Yorkville, \$8; 2nd do, Geo Palmer, Guelph, subject to proof of being pure bred, \$6.

Best thorough-bred stallion of any age, Ed. Arkland, Oshawa, Diploma.

Best three years old filly, James White, Bronte, "Annie Laurie," \$18; 2nd do, John Dew, Yorkville, \$11.

Best 2 years old filly, James White, Bronte, \$14.

Best yearling filly, Jas. White, Bronte, \$8.

Best mare and foal, or evidence that the foal has been lost, James White, Bronte, \$22; 2nd do, John Dew, Yorkville, \$14; 3rd do, Geo. Palmer, Guelph, subject to proof of being pure bred, \$6.

Extra prize—Thorough-bred mare in foal, James White, Bronte, subject to production of foal, \$6.

#### CLASS II.—AGRICULTURAL HORSES—(113 Entries.)

*Judges.*—Jacob Young, York, Co. Haldimand; John Bobier, Tyrconnell; Matthew Jones, Darlington.

Best stallion for agricultural purposes, Thos. Gowland, York, Grand River, \$40; 2nd do, Hector Scott, Brooklin, \$25; 3rd do, George Gowland, Woodbridge, \$12.

Best 3 years old stallion, Alexander Burgess, Agincourt, \$22; 2nd do, John Hewer, Guelph, \$14; 3rd do, James Ferris, Galt, \$7.

Best 2 years old stallion, Thomas Teasdale, Grahamsville, \$14; 2nd do, G. Higginbottom, Balsam, \$10; 3rd do, K. Graham, Belleville, \$7.

Best yearling colt, Robert Armstrong, Markham, \$8; 2nd do, Richard Power, Columbus, \$6; 3rd do, George Alton, Nelson, \$4.

Best agricultural stallion any age, Thomas Gowland, York, Grand River, Diploma.

Best 3 years old filly, George Scott, Woburn, \$18.

Best 2 years old filly, George Scott, Woburn, \$14; 2nd do, Charles Pilkey, Claremont, \$9; 3rd do, James Lawrie, Malvern, \$4.

Best yearling filly, George Gray, Mayfield, \$8; 2nd do, James Nimmo, Clark's Mills, \$6.

Best brood mare and foal, or evidence that the foal has been lost, Thomas Gowland, York, Grand River, \$22; 2nd do, Robert Beath, Darlington, \$14; 3rd do, John Moore, Islington, \$6.

Best span matched farm or team horses, John Clark, Brampton, \$20; 2nd do, Wm. Elford, jun., township of Darlington, \$15; 3rd do, Andrew Allison, Burnhamthorpe, \$10.

REMARKS BY JUDGES.—The judges beg leave to remark that the horses exhibited in this class were very superior, and show a great improvement upon former years, more particularly in the two year old stallions. The judges are of opinion that the system of publishing catalogues and placing them in the hands of judges should be dispensed with, and that the judges should not know who the exhibitor is, or where he came from. The judges would also suggest that, were there a second ring to exhibit the horses in it would greatly expedite business, as two sets of judges could then act at the same time.

#### CLASS III.—ROAD OR CARRIAGE HORSES— (171 Entries.)

*Judges.*—George Robson, Whitby; Alex. Alcorn, Cobourg; George Taylor, Belleville; Charles DeBlaquiere, Woodstock.

Best roadster or carriage stallion, 4 years old and upwards, James Armstrong, Yarmouth, \$40; 2nd do, Robert Stephens, Streetsville, \$25; 3rd do, J. E. Davis, Richmond Hill, \$12.

Best do, 3 years old, John Gibson, New-castle; 2nd do, J. S. Palmer, Rouge Hill, \$14; 3rd do, Marmaduke Laidman, Binbrook, \$7.

Best do, 2 years old, Jacob Stong, Yorkville, \$14; 2nd do, Thomas Webb, Toronto, \$10; 3rd do, Donald Robertson, Queenston, \$5.

Best yearling colt, John Colley, Mount Hurst, \$8.

Best stallion of any age, James Armstrong, Yarmouth, Dip.

Best French Canadian stallion, James John-

son, Cooksville, \$30; 2nd do, John Miller, Castleton, 20; 3rd do, James Fitzsimmons, St. Thomas, \$10.

Best 3 years old roadster filly, Thomas Smith, Derry West, \$18; 2nd do, John Boulton, Toronto, \$11.

Best 2 years old filly, George Miller, Markham, \$14; 2nd do, James Young, Mayfield, \$9.

Best brood mare and foal, or evidence that the foal has been lost, John Miller, Brougham, \$22; 2nd do, James Nimmo, Kingston, \$14; 3rd do, John Wilson, Oshawa, \$6.

Best span of draught horses, John Thompson, Whitby, \$20; 2nd do, James Lawrie, Scarboro, \$15; 3rd do, John Shedden, Toronto, \$10.

REMARKS BY JUDGES.—Great delay and consequent inconvenience therefrom was caused by the want of another horse ring, the necessity for which was felt last year, and a recommendation made by the judges to that effect. This season has shown more fully the requirement of such additional ring, as the judges in this class have only been enabled to make their return at this late hour of Thursday at five o'clock. The wrong classing of animals has caused much trouble to the judges, as well as probable losses to the owners; at least the judges in this class had to pass over animals that might have been worthy of prizes if entered in their proper class. But this is a difficulty which must only be remedied by the exhibitors, but the suggestion is offered in the hope that the committee may devise some method to obviate the error for the future.

#### CLASS A.—HORSES OF ANY BREED.—(51 Entries.)

*Judges.*—A committee of the judges of all the other classes of horses.

The best stallion of any age or breed, Jas. Armstrong, Yarmouth, Elgin, DIPLOMA AND GOLD MEDAL.

### CATTLE.

Best bushel of buckwheat, Ben Johnston, Islington, \$4; 2nd do, P. Bartholomew, Ringwood, \$2; 3rd do, P. R. Palmer, Thurlow, Trans.

REMARKS BY JUDGES.—The judges of grains and seeds have pleasure in presenting their report. Upon former occasions much difficulty has arisen from the erroneous classification of various articles in this class, but this year very few instances have been found where these mistakes have been made. Where such were found we took it upon ourselves to set them to rights. In some of the sections we found a great deficiency both in quantity and quality. Considering that one of the objects of the Association is to encourage competition by awarding prizes only to such articles as are worthy of them, we have in one or two instances not awarded any prize on account of the articles not coming up to the standard of quality, but we are happy to say that these are exceptional cases. In other instances we have withheld prizes for want of sufficient quantity to comply with the rules of the Association.

#### CLASS XXX.—ROOTS AND OTHER HOED FIELD CROPS.—(386 Entries.)

Judges.—John Menzies, Almonte; John Randall, Newmarket; Walter Riddell, Cobourg.

Best bushel of pink-eyed potatoes, John Ross, Toronto, \$3; 2nd do, Richard Rispen, London, \$2; 3rd do, Adam Mather, Islington, \$1.

Best bushel cup potatoes, John McCallum, Beverly, Wentworth, \$3; 2nd do, John Ross, Toronto, \$2; 3rd do, Robert Worm, Lippincott, \$1.

tie, Nichol; Peter C. Servos, Niagara.

Best 12 roots of salsify, Edward Lewis, Yorkville, \$2; 2nd do, Geo. Tattle, Yorkville, \$1 50; 3rd do, Geo. Vair, Yorkville, \$1.

Best 3 heads brocoli, Richard Guthrie, Toronto, \$2; 2nd do, do, \$1 50; 3d do, Wm. Burgess, Mimico, \$1.

Best 3 heads cauliflower, Ed. Lewis, Yorkville, \$2; 2nd do, Richard Guthrie, Toronto, \$1 50; 3rd do, J. C. Small, Toronto, \$1.

Best 2 heads cabbage [summer] James Fleming, Toronto, \$2; 2nd do, A. W. Taylor, Hamilton, \$1 50; 3rd do, G. Tattle, Yorkville, \$1.

Best 3 heads of cabbage (winter) Richard Guthrie, Toronto, \$2; 2nd do, Wm. Burgess, Mimico, \$1.50; 3rd do, Jas. R. Todd, Brampton, \$1.

Best 4 sorts of winter cabbage, including savoy, 1 of each sort, W. Burgess, Mimico, \$3; 2nd do, W. Holden, Yorkville, \$2; 3rd do, R. Guthrie, Toronto, \$1.

Best 3 heads red Cabbage, A. W. Taylor, Hamilton, \$2; 2nd do, W. Burgess, Mimico, \$1.50; 3rd do, R. Guthrie, Toronto, \$1.

Best 12 carrots for table, long red, Samuel Ashby, Toronto, \$2; 2nd do, W. Burgess, Mimico, \$1.50; 3rd do, W. Benham, Guelph, \$1.

Best 12 early horn carrots, J. C. Daniels, Yorkville, \$2; 2nd do, James Young, Chester, \$1.50; 3rd do, Judge Harrison, Toronto, \$1.

Best 12 table parsnips, Alfred Strowger, Guelph, \$2; 2nd do, W. Benham, Guelph, \$1.50; 3rd do, G. S. Armstrong, Fergus, \$1.

Best 6 roots of white celery, James Best, Ashport, \$2; 2nd do, W. Daniels, Yorkville, \$1.50; 3rd do, G. Tatler, Yorkville, \$1.

Best 6 roots red celery, James Wildes, Hamilton, \$2; 2nd do, John Nicholson, Ashport, \$1.50; 3rd do, W. Daniels, Yorkville, \$1.

Best dozen capsicums (ripe), R. C. Gill, Colborne, \$2; 2nd do, Judge Harrison, Toronto, \$1.50; 3rd do, J. M. Grover, Colborne, \$1.

Best collection of capsicums (ripe,) 6 of each sort, A. W. Taylor, Hamilton, \$3; 2nd do, C. C. Fearnside, Hamilton, \$2; 3rd do, R. C. Gill, Colborne, \$1;

Best 3 egg plant fruit, purple, W. A. F. Currie, Niagara, \$2; 2nd do, R. Currie, St. Catharines, \$1.50; 3rd do, H. Girouard, Hamilton, \$1.

Best 12 tomatoes, [red] J. D. Humphreys, Toronto, \$2; 2nd do, Rev. Mr. Cox, Brampton, \$1.50; 3rd do, Edward Lewis, Yorkville, \$1.

Best 12 tomatoes, [yellow] W. R. Bartlett, Toronto, \$2; 2nd do, R. Rispin, London, \$1.50; 3rd do, H. Girouard, Hamilton, \$1.

Best assorted collection of tomatoes, 6 each of large sorts, and 12 each of small sorts, E. C. Fearnside, Hamilton, \$3; 2nd do, Thos. Ironfield, Toronto, \$2; 3rd do, J. D. Humphreys, Toronto, \$1.

Best 12 blood beets, long, Gage J. Miller, Virgil, \$2; 2nd do, Sam Ashby, Toronto, \$1.50; 3rd do, James Fleming, Toronto, \$1.

Best peck of white onions, A. W. Taylor, Hamilton, \$2; 2d do, Henry Girouard, Ham-

ilton, \$1.50; 3rd do, James Wildes, Hamilton, \$1.

Best peck of yellow onions, A. W. Taylor, Hamilton, \$2; 2nd do, R. Rispin, London, \$1.50; 3rd do, James Wildes, Hamilton, \$1;

Best peck of red onions, John Young, Virgil, \$2; 2d do, R. Rispin, London, \$1.50; 3rd do, James Wildes, Hamilton, \$1.

Best 12 white turnips [table] Thomas Ironfield, Toronto, \$2; 2nd do, A. W. Taylor, Hamilton, \$1.50; 3rd do, George Vair, Toronto, \$1.

Best 12 yellow turnips [table] A. W. Taylor, Hamilton, \$2; 2nd do, Thomas Ironfield, Toronto, \$1.50.

Best 12 ears sweet corn, John Young, Virgil, \$2; 2nd do, G. J. Miller, Virgil, \$1.50; 3rd do, James Durand, Kingston, \$1.

Best and greatest variety of potatoes, half peck of each sort, named, Richard Guthrie, Toronto, \$3; 2nd do, Samuel Ashby, Toronto, \$2; 3rd do, A. W. Taylor, Hamilton, \$1.

Best 3 squashes, [table] S. J. J. Brown, Niagara, \$2; 2nd do, James Fleming, Toronto, \$1.50; 3rd do, R. L. Denison, Toronto, \$1.

Best and greatest variety of vegetables, [distinct from other entries] each kind named, George Tattle, Yorkville, \$4; 2nd do, A. W. Taylor, Hamilton, \$3; 3rd do, James Best, Ashport, \$2.

EXTRA PRIZES.—Curled parsley, Wm. Benham, Guelph, 50c. Three kinds of kidney beans, J. D. Humphreys, Toronto, 50c. Dish of Russian peas, and dish of asparagus beans, J. M. Hirschfelder, Toronto, 50c. Asparagus beans, George Tattle, Yorkville, 50c. Variety of dried garden herbs, George Tattle, Yorkville, 50c. Dish of yard beans, long pole, Jas. Best, Ashport, 50c. Dish of green peas, J. D. Humphreys, Toronto, 50c. Brace of cucumbers, Geo. Leslie, Toronto, 50c. Dioscorea batatas, Bruce & Murray, Hamilton, 50c. Dioscorea batatas, Judge Harrison, Toronto, 50c. Half-peck champion of England peas, George Tattle, Yorkville, 50c. Green peppers, J. C. Small, Toronto, 50c. Bassano turnip beet, J. C. Daniels, Yorkville, \$1. Best Siberian crabs, Robert Stibbard, Eglinton, 50c. Strawberry tomato in the husk, James Lesslie, township of York, 50c. Collection of gourds, J. D. Humphreys, Toronto, 50c.

(Prize List to be concluded in next number.)

### Miscellaneous.

**AGRICULTURE AND WOMEN.**—An American gentleman who lately visited England was struck by the interest manifested by ladies, including those of the highest rank, in agriculture. One of these, the Duchess of Portland, exhibited perfect familiarity with the minutest details of farm management and work, showing her American guest over the whole of the Duke's large estate, and explaining to him the various processes and methods of cultivation. We could wish that our American ladies would adopt one of the few aristocratic tastes and habits which sit gracefully upon republican women, and which would be of equal advantage to the interests of agriculture and to their own delicate physical organizations. A great deal of cant is uttered in these days about the mission of woman, but whenever we hear an attenuated, dyspeptic female talking in this wise, we feel sure that the daily handling of a broomstick, in a peaceable manner, or the charge of a kitchen garden, would soon put her upon the track most useful for herself and for society. When Rome was young and virtuous, the kitchen garden was always placed under the care of the mother of the family. In Sparta, the women, fit to be the mothers of heroes, cultivated the soil, whilst the men were fighting the battles of their country. Indeed, from the earliest period in the annals of our race, woman has aided by her counsels, and sometimes by her labors, in bringing agriculture to a state of perfection. The laws which Osiris gave to Egypt were not as valuable to that country as those precepts in agriculture, those instructions in embankments, irrigations and drainings, which Isis, his Queen, gave to the Egyptians, and which enabled them to derive so much benefit from the deposits of the Nile. Ceres, deified by the Greeks, made her people acquainted with the use of wheat, and the mode of cultivating it. To the Empress of China we are indebted for the mulberry tree and the rearing of silk worms. Woman of late years has demonstrated her capacity of shining in many spheres once considered the peculiar province of man. Miss HERSCHEL has discovered comets; Mrs. SOMERVILLE laid open the mathematical structure of the universe; some have analyzed the chemical relations of nature in the laboratory, and others investigated the laws of social relations. With such a great amount and variety of power, may we not augur the most beneficial results to agriculture, if the women of our country, by their sympathy, encouragement and co-operation, by their studies and counsels, would prove themselves, as did the women of old, helpmeets to him whom God has ordained to cultivate the earth?—*Baltimore American.*

**NATURAL BAROMETER.**—The spider, says an eminent naturalist, is almost universally regarded with disgust and abhorrence; yet, after all, it is one of the most interesting, if not the most useful, of the insect tribe. Since the days of Robert Bruce, it has been celebrated as a model of perseverance, while in industry and ingenuity it has no rival among insects. But the most extraordinary fact in the natural history of this insect, is the remarkable presentiment it appears to have of an approaching change in the weather. Barometers, at best, only foretell the state of the weather with certainty for about twenty-four hours, and they are very frequently fallible guides, particularly when they point to *settled fair*. But we may be sure that the weather will be fine twelve or fourteen days, when the spider makes the principal threads of its web very long. This insect, which is one of the most economical animals, does not commence a work requiring such a great length of threads, which it draws out of its body, unless the state of the atmosphere indicates with certainty that this great expenditure will not be made in vain. Let the weather be ever so bad, we may conclude with certainty that it will soon change to be *settled fair* when we see the spider repair the damages which his web has received. It is obvious how important this infallible indication of the state of the weather must be in many instances, particularly to the agriculturist.

**A PLEA FOR ROOTS.**—A correspondent of the *Rural New Yorker*, thus urges farmers to cultivate roots:—"A few acres of roots for home consumption should be raised on every farm. In behalf of horses, cattle, sheep, and swine, I plead earnestly for roots. Fed as cattle are in winter, with hay and straw only, who, I ask, would not call it dry fodder? A peck of turnips, beets, or carrots fed to each animal would be pleasant to them, and profitable to their owner. Horses should, by all means, have carrots. They eat them without cutting, grow fat and sleek. Turnips cut up fine and fed to sheep in spring when they get tired of hay, are of great benefit. Piggy, too, likes roots, though like some other folks he prefers to have them cooked. As a means of promoting the health of stock they are unsurpassed, and at the risk of incurring the displeasure of the M. D's, I assert they are far superior to pills or physic. A strong argument in favor of roots is the great quantity that may be grown upon an acre as compared with other crops. True, it is some work to get down on the hands to weed them when small, but then it tends highly to promote that almost extinct virtue, humility. Savages and barbarians live without cultivating the soil; let us resemble them in this respect no longer."

**CANARIES**—Rather more than three hundred years ago a ship was partly laden with little green birds captured in the Canary Islands, and having been wrecked near Elba, the birds made their escape, flew to the island, and there settled themselves. Numbers of them were caught by the inhabitants, and on account of their sprightly vivacity and the brilliancy of their voice they soon became great favourites, and rapidly spread over Europe. The original colour of the canary is not the bright yellow with which its feathers are generally tinted, but a kind of dappled olive-green, black, and yellow, either colour predominating according to circumstances. By careful management, however, the bird-fanciers are able to procure canaries of every tint between the three colours, and have instituted a set of rules by which the quality and arrangements of the colouring is reduced to a regular system. Still, the original dappled green is always apt to make its appearance; and even when two light-coloured birds are mated, a green young one is pretty sure to be found in the nest. For my own part, I care little for the artificial varieties produced by the fanciers; and to my mind, an intelligent bird and a good songster is not one whit less attractive because the colours of his plumage are not arranged precisely according to the fanciers' rules.—*Rouledge's Natural History*.

**DANGER OF CHECKING PERSPIRATION**.—A medical journal publishes a severe caution against allowing perspiration to be suddenly checked. All who are condemned to "eat their bread in the sweat of their brows," should give heed to this advice. As one illustration of the evils resulting from the practice which it condemns, the following case, divested of technicalities, may be cited: A Boston merchant having worked pretty hard on board one of his ships on a windy day, found himself exhausted and perspiring freely. He sat down to rest. The cool wind from the sea was delightful, and engaging in conversation, time passed faster than he was aware. In attempting to rise, he could not do so without assistance. He was taken home and put to bed, where he remained for two years, and for a long time could only hobble about on a crutch. Such exposures frequently result in inflammation of the lungs, pneumonia, ending in death in less than a week, or tedious rheumatic affections. Multitudes of lives would be saved every year, if parents would explain to their children the danger which attends cooling off too quickly after exercise, and the importance of not standing still after work or play, remaining exposed to a wind, or sitting at an open window or door, or pulling off any garment, even the hat or bonnet, while in a heat. It should be remembered that a cold never comes without a cause, and that in four times out of five, it is the result of leaving off exercise too suddenly, or remaining still in the wind, or entering while

heated a cooler atmosphere than that in which the exercise has been taken.

**ONLY A PENNY**.—The true secret of frugality is to lay up small savings. Most people never begin to save because they fancy they have not a sum worth saving. Begin with a penny: now, this very day, and every day contrive to save a penny. At the end of the year you will have £1 10s. 5d. This sum would buy some good tools, or a good piece of household furniture, or useful articles of dress, or a number of interesting books; and it would be a pleasure to you every time you looked at what you had bought out of your penny saving. If you choose not to spend it, but to put it into the savings' bank, in five years you would have between £8 and £9, which would be a very valuable sum that might help you in many ways.—*British Workman*.

**HOW THE SAVAGES OBTAIN WATER**.—Livingston, the African traveler, describes an ingenious method by which the Africans obtain water in the desert.

The women tie a bunch of grass to one end of a reed about two feet long, and insert it in a hole dug as deep as the arm will reach, they ram down the wet sand firmly around it. Applying the mouth to the free end of the reed, they form a vacuum in the grass beneath, in which the water collects, and in a short time rises to the mouth. It will be seen that this simple, but truly philosophical and effectual method might have been applied in many cases in different countries where water was greatly needed to the saving of life.

**THE MAGNITUDE OF BRITISH TRADE**.—If London held so high a place among the great exchanges of the world in the time of the second Henry, it now far outstrips all other competitors, though the whole of northern Europe has advanced. Hiram of Tyre spurned the gift of Solomon's cities in a consciousness of the grandeur of his own capital, that doubled itself in the blue waters of the Mediterranean; to have his own opinion on the magnitude of London and the extent of its trade would be a fine test of a shrewd and sober thinker for comparison. Carthage and Alexandria sink into the position of mere classic bazaars, if we attempt to estimate them statistically by the data of our own commerce; and Byzantium and Venice must trust to their art for a place in history, now that their commercial boundaries are so far overpassed by that of a city which sends its ships to every sea, and gives new life and hope to peoples rendered imbecile by centuries of superstition and cruelty. In 1860, the import and export trade of Great Britain amounted to no less than the sum of three thousand and seventy-five millions sterling, to the greater part of which the city and port of London, directly or indirectly acted as supercargo, ship's husband, banker, and customer at first hand.—*City Press*.

### Receipt for Rhubarb Wine.

Some time since we noticed a sample of Rhubarb Wine, sent us by Mr. C. D. Stevens, of La Salle Co., Ill. It was pronounced a very fine article by all who tasted it. Mr. S. gives in his method of making the wine as follows:

"I strip the leaves from the stalks, and crush the latter in a sugar mill, and press them in a press having a three-inch screw. For a 40 gallon barrel I put into a mixing tub 20 gallons of juice, 140 lbs of best brown sugar, and water enough to make 40 gallons. Mix well, and pour into the barrel, leaving the bung open, and keeping the barrel full until it is done working, and then bung tight for six weeks. Then dissolve 4 oz. of isinglass in warm wine, pour it into the barrel and bung tight, leaving it so for a year; then rack off and it is fit for use, but it will be much better at two years, and so on, the older the better. The sample I sent you is one year and eight months old.

I have plants enough this season to make 200 barrels or more. Am making it on shares as follows: any one furnishing sugar sufficient for two barrels, I make the wine and furnish the barrels, (keep it for them if they wish) and deliver them one barrel. If they furnish sugar and barrels for 12 bbl., I return them eight of wine. The wine I sent you, brought me \$2 per gallon. I could readily get \$3 for it now, if I had it to sell. June is the best time to make this wine."

WONDERS OF THE DEEP.—What a beautiful place would be the bed of the ocean, if we could only have an opportunity to contemplate its vastness without fear, and with an opportunity to descend in safety to its profound depths and investigate, with ease, all its mysteries! What a delightful chance, provided the personal safety of the explorer was secured, to spy out the pearly secrets, to gaze on the so-long-hidden gorgeousness of the silent caves and coral palaces, the forests and plains, the mountains and valleys of the submarine world. But the truth is that even if the sea were temporarily exhausted of its billows to accommodate our curiosity, it would be too dangerous in its thick, deep, unctuous bed, for human footsteps, and would be too fatal to life in its rank exhalations to leave us a hope of adding much to our stock of knowledge as to its marvels. The curled, deep-purpled leaves of the sea-lettuce, cover, no doubt, the bed of the ocean, and lie deeply intermixed with the large porous lichens; the many branched hollow algæ, full of life and motion in their rosy little bladders, thickly set with ever-moving arms. Seen from a height, the mass of luxuriant vegetation would present the appearance of a gay carpet brilliantly set off with shining ornaments, for among the leaves we might just catch a glimpse of the showily-painted molluscs;

the rainbow-tinted fish; the gigantic angang, the siren of the ancients; the shark, with his leaden eyes; the thick-haired sea-leopard, and the lazy turtle. And what a picture it would be!

UGLY INSECTS.—[To "G. G.," written on reading his contribution to *The Field*, of April 5, wherein he says "worms, beetles, ants, and other ugly insects."]

"The sage, and the beetle at his feet, have each a ministration to perform."—TUPPER.

Oh, term not insects "ugly!"

There never yet was one  
Of God's created creatures,  
Since earth from chaos sprung.  
But that possessed beauty,

Or proved a purpose wise;  
So think of him who made them,  
And ne'er their form despise.

Ants are endowed with instinct  
So wonderfully great,  
That men with reason gifted,  
Might them their models make,  
In various daily matters  
Pertaining to this earth;  
For industry and foresight  
Are traits of sterling worth.

There's beauty in the beetle—  
Look at his burnish'd wing;  
And usefulness—he clears the ground  
Of many a noisome thing.  
And so he aids to till the soil:

Thus we should ne'er condemn  
His form as "ugly," nor forget  
The good he does for men.

The earthworm is not lovely  
To look upon, I ween,  
But many a serious lesson  
We from a worm may glean.  
Did we but rightly ponder  
That sad yet true decree—  
"The worm, she is thy sister,"  
How humble we should be!

Then call not insects "ugly,"  
For God has made them all:  
The huge gigantic white ant,  
And ladybird so small.  
They all possess some virtue,  
Are objects of His love,  
Who says that not a sparrow falls  
Unknown to God above.

THE CAEN SOCIETY OF AGRICULTURE AND COMMERCE, founded in 1762, has just celebrated its hundredth anniversary—a fact which shows that there is more "solidarity" in the French rural character than many persons would be disposed to imagine. The society has especially devoted itself to the improvement of the pure Norman breed of stock, which it has contended

is capable of amelioration *per se*, like all choice races, and it has constantly discouraged the introduction of foreign blood, whatever might be its merit. The amelioration and conservation of the milking qualities of the breed have been particularly kept in view, and the society imposes on its "laureats," or principal prizemen, the condition of keeping prize bulls in the district for six months at least, and cows for a year, in order that the rewards given may not be turned to exportation account, and the stock rewarded lost to the locality.

**RULES FOR READING.**—Read much, but not many works. For what purpose, with what intent, do we read? We read not for the sake of reading, but we read to the end that we may think. Reading is valuable only as it may supply to us the materials which the mind itself elaborates. As it is not the largest quantity of any kind of food taken into the stomach that conduces to health, but such quantity of such a kind as can be best digested; as it is not the greatest complement of any kind of information that improves the mind, but such a quantity of such a kind as determines the intellect to most vigorous energy. The only profitable kind of reading is that in which we are compelled to think, and think intensely; whereas that reading which serves only to dissipate and divert our thoughts, is either positively hurtful, or useful only as an occasional relaxation from severe exertion. But the amount of vigorous thinking is usually in the inverse ratio of multifarious reading. Multifarious reading is agreeable; but as a habit it is, in its way, as destructive to the mental, as dram-drinking is to the bodily health. "Our age," says Herder, "is the reading age;" and he adds, "it would have been better, in my opinion, for the world and for science, if, instead of the multitude of books which now overlay us, we possessed but a few works good and sterling, and which few would, therefore, be more diligently and profoundly studied."—*Sir Wm Hamilton.*

### Editorial Notices, &c.

---

THE WESTMINSTER REVIEW, October, 1862.  
—BLACKWOOD'S MAGAZINE, October, 1862.

We have received, through Mr. Rowsell, of this city, from Leonard, Scott & Co., New York, the American Edition of the Standard British Periodicals.—The *Westminster* contains its usual quantity and variety of ably written articles. The one on Slave Power will be read with great interest on this side of the Atlantic, at the present critical time. Among the other articles that will attract

general attention may be mentioned: Essays and Reviews; Dr. Lushington's Judgment thereon; The British Sea Fisheries; Railways, their Cost and Profits; Gibraltar; The Encyclopædia Britannica; The Religious difficulties of India; with the usual elaborate article on Contemporary Literature.

*Blackwood* is as rich and racy as ever. The October number contains a continuation of those pleasant serials—*Caxtoniana*, and the *Chronicles of Carlingford*; Italy and France; with an exceedingly interesting paper to our reader generally, called *Ten days in Richmond*.—We most strongly recommend these well executed Reprints, belonging to the very highest standard of British Literature, to all that desire to keep pace with correct thought and opinion on the leading questions of the day, at the smallest possible expense. The four British Quarterlies and *Blackwood's Magazine* at \$10 a year, must be regarded as a miracle of cheapness.

THE ILLUSTRATED ANNUAL REGISTER of Rural Affairs for 1863. Albany, N. Y: Luther Tucker and Son.

The ninth annual issue fully sustains the high and useful character of the *Register of Rural Affairs*. It is "got up" in the neatly executed style which characterises the Messrs. Tucker's publications, and is ably edited by the well known agricultural and horticultural writer, J. J. Thomas. The present number consists of 130 pages, with 140 well executed engravings, embracing a great variety of subjects connected with the farm, garden and household, and all for the marvelously low price of 25 cents! The publishers offer most liberal terms for its introduction in quantities either to Agents, Agricultural Societies, Nurserymen, Dealers in Implements and Seeds, or any others who may take an interest in the dissemination of useful reading, and in the promotion of Rural Improvement.—We shall be happy to know that the *Rural Register*, and also the *Country Gentleman* (weekly), and the *Cultivator* (monthly), are having an increasing circulation throughout the British Provinces. They are publications of the highest reputation.

**Pure Bred Stock for Sale.**

**A**YRSHIRE BULLS, Calves, and Heifers; Improved Berkshire Pigs, and Leicester and Cotswold Rams.

R. L. DENISON,  
Dover Court, Lippincott P. O.

**FOR SALE!**

**Avrshire Cattle, Leicester Sheep, and Berkshire Pigs.**

**T**HE Subscriber offers several Young Bulls, Heifers and Cows, on very Liberal Terms. Specimens from his *Prize Herd* will be on Exhibition at Toronto, if all's well.

P. R. WRIGHT, Cobourg. C. W.  
Aug. 30th, 1862. 6 mos.

THE  
**JOURNAL OF THE BOARD OF ARTS  
AND MANUFACTURES,  
FOR UPPER CANADA,**

Is Published on the first of every Month,

At \$1 per annum for single copies, or to clubs of ten or more at 75 cents. per copy; to members of Mechanics' Institutes, and of Literary, Scientific, and Agricultural Societies, through their Secretary or other officer, 50 cents per annum per copy.

Subscriptions payable in advance.

Printed for the Board of Arts and Manufactures for Upper Canada, by W. C. CHEWETT & Co., King Street East, Toronto.

**DUTCH FLOWER ROOTS.**

**T**HE SUBSCRIBERS BEG TO ANNOUNCE that they have just received their annual importation of Bulbs in good condition—consisting of *Double and Single Hyacinths*, \$1 00, \$2.00, and \$3 00 per dozen. A fine assortment of *Tulips*, from 50 cents to \$2.00 per dozen. *Crocus*, 12 to 20 cents per dozen, and at \$1.00 and \$1.50 per 100. *Polyanthus*, *Narcissus*, 12 to

15 cents each.

Descriptive Catalogues furnished gratis on application. They would also call attention to their fine stock of English Hyacinth Bottles, with supports, suitable for growing Hyacinths in winter, and for holding parlour bouquets in summer. (See above cut)

**JAMES FLEMING, & Co.,**

Seedsman and Florists, Corner of Yonge and Queen Streets, Toronto

25th, 1862.

## Agricultural and Veterinary Instruction.

A CLASS will be formed in Toronto for instruction in the Principles of Agriculture, and the Veterinary Art, specially adapted to the wants of young men engaged in, or intended for agricultural pursuits.—Professor Buckland will be assisted in the department of Scientific Agriculture by the Professors of Chemistry, Geology and Natural History in University College.—Mr. A. Smith, Licentiate of the Edinburgh Veterinary College, and consulting Surgeon to the Board of Agriculture for UPPER CANADA, will have charge of the Veterinary department.

The course will commence on *Wednesday, January 21st, 1863*, and continue for about six weeks. Three Lectures a day, and *no fees*.—The subjects treated of will comprise:—

The History, Breeding, Diseases, and Treatment of Farm Animals,—including their Anatomy and Physiology, with a course of instruction in Practical Dissecting.

Agriculture in its relations to Chemistry, Geology, Mechanics, Physical Geology and Meteorology, Botany and Zoology, including Farm Architecture and Engineering, the valuation and management of Landed Property, with special reference to Canada.

Pupils may enter and leave the Class without being subjected to an examination. But with a view of promoting Emulation the Board of Agriculture offer the following Prizes, the value to be given in suitable books:—First, \$20 to the Student who shall pass the best Examination in all the subjects at the end of the term Second, \$15; Third, \$10; and Fourth, \$5.

Further particulars may be known by applying either personally or by letter to Professor Buckland, University College.

Toronto, Nov., 1862.

## The Agriculturist,

OR JOURNAL AND TRANSACTIONS OF THE BOARD  
OF AGRICULTURE OF UPPER CANADA,

IS published in Toronto on the 1st and 16th of each month.

**Subscription**—Half a dollar per annum for Single copies; Eleven copies for Five Dollars Twenty-two copies for Ten Dollars, &c.

**Editors**—Professor Buckland, of University College, Toronto, and Hugh C. Thomson, Secretary of the Board of Agriculture, Toronto, to whom all orders and remittances are to be addressed.

Printed at the "Guardian" Steam Press, King Street East, Toronto.

## Horse Infirmary and Veterinary Establishment, Corner of Bay and Temperance Streets Toronto, C. W.

A SMITH, Licentiate of the Edinburgh Veterinary College, and Veterinary Surgeon to the Board of Agriculture of U. C., begs to return his thanks to the Public generally for their support since opening the above mentioned establishment, and respectfully solicits a continuance of the same.

And also begs to announce that Veterinary Medicines of every description are constantly kept on hand:—Such as, Physic, Diuretic, Cough Cordial, Tonic Condition, and Worm Balls and Powders. The constituents composing the Cough-balls, have been found (by Professor Dick, of Edinburgh) most serviceable in alleviating many of the symptoms of Broken-wind or Heaves in Horses. Colic Draughts, &c., a mixture which owners of Horses should always have beside them.

Liniments for Sore-throat, Sprain, Curb, Spavin, Ringbone.

Blistering Ointments. Liquid and sweating Blisters.

Horses bought and sold on commission.

Toronto, Aug. 30th, 1862.

THE  
Canadian Agriculturist,

OR

JOURNAL AND TRANSACTIONS OF THE BOARD OF AGRICULTURE  
OF UPPER CANADA.

VOL. XIV.

TORONTO, DECEMBER 16, 1862.

No. 24.

Close of the Year.

With this issue the volume of the *Agriculturist* for 1862 is completed; a year that has been pregnant with great events both in the old world and the new. In Europe thrones have been jeopardized, and commerce, especially the cotton manufacture, paralyzed; while on this continent the event which stands out in boldest relief in the whole course of its history,—the Civil War of the adjoining and hitherto happy and prosperous Republic,—has continued to be waged with increasing violence and desolation, with, we grieve to say, no immediate prospect of its being brought to a satisfactory termination. In Canada we have been blessed with peace, and, in most sections, with what may be considered on the whole an average, if not a bountiful harvest; circumstances that should call forth in every heart devout thankfulness to the Giver of all good. In the enjoyment of these inestimable blessings—peace and plenty—and possessing, under British Institutions, civil and religious liberty in its fullest application, it was becoming in us as a christian people to assemble together as was done the other day in the various places of worship throughout the land, in compliance with a proclamation of His Excellency, the honored Representative of our beloved Sovereign, to return thanks to Almighty God for the continuance of His mercies to us as a people, forming an integrant portion of the vast Empire of Britain. It is devoutly to be

wished that, being thus favoured by a gracious Providence, we may, as a people, rightly use the privileges and opportunities afforded us in continuing to improve our agriculture and all other industrial arts; living in unity and charity among ourselves, and cultivating a kindly and pacific spirit towards all our fellow creatures. With such thoughts and aspirations as these we are about closing our editorial labors for the year.

With respect to those labors it may at this time be permitted us to observe that no one can be more sensible of their imperfection and shortcomings than ourselves. With but little assistance from Societies and individuals in furnishing materials for our pages, it must be obvious to such as have an acquaintance with the management of agricultural periodicals, that *more time and practical information* are required of the conductors of a *fortnightly* publication, that it may have all the desirable characteristics, than we are able to command. To the pens that have rendered us aid by favoring us with contributions we hereby tender our hearty thanks, and trust that articles from their pens will enrich the pages of our next volume. Again we importune such as feel an interest in the objects of this journal, to send us occasional papers on subjects coming within the range of their practice, reading or observations; such contributions, however short or homely, will be always acceptable.

In consequence of the recent and great advance in the price of paper and the scarciness

of communications either from our agricultural societies or practical farmers, it has been deemed expedient to publish this journal henceforth *monthly*, commencing with the new year. The single number will be larger than one of our heretofore semi-monthly nos., and greater attention paid both in reference to the brevity and variety of the articles.—We shall introduce a larger number of illustrations in the next volume, the numbers will be published regularly on the first of the month, and there will be a marked improvement generally in its mechanical execution. The Veterinary Department will be enlarged and improved under the editorial supervision of Mr. Smith, Consulting Veterinary Surgeon to the Board of Agriculture, who has established himself in practice in this city, where he gives stated instruction in the Veterinary Art to all young men disposed to avail themselves of the opportunity, for about six weeks during the winter. (See Advertisement.)

Each number of our next year's volume will contain at least 40 pages, of the same size as at present, but we shall not be strictly confined to this number of pages. We shall occasionally, when circumstances render a greater space desirable, give 48, or perhaps 64 pages in a number, but as a general rule for the incoming year, each number of the journal will consist of 40 pages, and will be neatly stitched together and trimmed before being sent to the subscribers.

The price for single copies, will be the same as heretofore, half a dollar per annum; but to Agents, officers of Agricultural Societies, or Clubs, sending lists of subscribers, a considerable reduction will be made. The reduction will be in the shape of a discount, on the following progressive scale, viz:

To any person sending an order accompanied with the cash for 5 Copies and upwards, and under 20 copies, 10 per cent discount,—  
 20 copies and under 35 copies 15 per cent. dis.  
 35 “ “ 50 “ 20 “ “  
 50 “ and upwards, 25 per cent. discount will be allowed.

Or to state the same thing in other words, it will be seen that for any number of copies between 5 and 20, the price will be 45 cents. per copy.

Between 20 and 35 copies, 42½ cents per copy.  
 “ 35 and 50 “ 40 “ “

For 50 copies and upwards, 37½ cts. per copy.

Any person sending an order for a sufficient number of copies to entitle him to one of the smaller rates of discount, and afterwards increasing the order sufficiently to entitle him to a higher rate, will of course be allowed the higher rate on the whole order.

It is to be understood that the cash must always accompany the order, and the party sending the order will deduct from the amount the discount he is entitled to.

Our readers will please bear in mind that it is our invariable practice to discontinue sending our Journal to subscribers on the close of the term for which the subscription has been paid. The amount of subscription for each copy is so small, that to continue sending the paper after the close of the year, before the order has been renewed, would involve open accounts all over the country for trifling amounts, the collection of which would be exceedingly inconvenient, and would be attended by a large additional expense. We have therefore adopted the only system practicable in such a case, viz: to send out no papers till they are ordered and paid for in advance. Those of our readers therefore who wish the paper continued, and we hope that *all* will so, will please renew their subscriptions as soon as possible, either individually, or through their usual Agents. The paper will be mailed direct to the address of each subscriber on the list of any agent, or sent in bulk to the latter, as he may desire.

It is hoped that these terms will prove satisfactory to our subscribers. The *Agriculturist*, our readers will recollect, is post free. It will still be, as it has been heretofore, the cheapest publication of the kind on the continent, and we hope, with the aid of our subscribers and contributors, to make it the *best*, at least for Canada.

### Liebig's Lectures on the Application of Chemistry to Agriculture.

(Concluded from page 679.)

No one can for a moment doubt the great importance agriculture has acquired in Germany by the establishment for its instruction, founded by Thaer in the year 1807. But the agricultural colleges, founded ultimately on the same model, have done more harm than good to the science—they have the shell, but not the nut of

the school at Moeglin. We know that Thaer was not renowned as an agriculturist, but as a doctor; he was a man who had received a deep scientific education, and all his merit consisted in his being the first to apply the knowledge he had gained in science to practical agriculture. No agriculturist would confirm his agricultural calculations on the net cost and gain, or carry out the idea of net and gross produce, without a knowledge as deep as Thaer's of political economy. Without possessing the philosophical education of Thaer, it would be impossible to draw out certain rules for guidance by the help of agricultural facts as innumerable as incomprehensible. It would be still more difficult to apply the natural sciences to agriculture without a knowledge of natural history. The lessons of Thaer were so useful, not merely because he was a practical, but more because he was a scientific man.

In the time of Thaer a young man could acquire no knowledge of physics, chemistry, botany, geognosy, or mathematics, without a university course. Thaer, who saw the great service all these sciences would be to agriculture, was obliged to introduce a part of each theory into the plan of studies he traced for Moeglin. These are the accessory circumstances which caused the annexation of a rural estate, serving as a means of instruction in practical agriculture, and a school where all the accessory sciences could be taught under the able direction of Thaer, who knew so well how to preserve a proper relation between theory and practice. This double direction given to the studies was useful, but it became the source of great evil to agriculture itself, because it was kept up in all the agricultural colleges subsequently founded: the result being, that the direction of these establishments was given to men possessing a knowledge of the practices necessary for the conductor of rural improvements.

Unfortunately, as it was impossible to find men possessing practical knowledge of all parts of agriculture, the choice was confined to those who were capable of managing the culture of wheat or artificial meadows. But the society exposed itself by committing serious errors in measuring the ability of a man by the superiority which he manifested in one special thing; because his exceptional abilities depended upon the care, order, and activity which he displayed, on the fitness or composition of the soil—in fact, a thousand things which cannot be taught in a school.

It is true, the culture of wheat and fodder is the principal aim of agriculture, because bread and meat stand before all other produce—such as beetroot, oats, flax, tobacco, and the vine; as the development of commerce does not permit them to be considered of any significant value. For the same reason, one has a right to say that the making of sulphuric acid includes all manufactures not mechanical. However,

the culture of wheat does not constitute the whole of agriculture any more than the fabrication of sulphuric acid constitutes the whole of chemical arts. It would be as absurd to appoint as director of a school of practical chemistry and chemical arts a manufacturer of sulphuric acid because he had distinguished himself in his trade, as it would be to place at the head of an agricultural academy men whose whole talents consist in being able to raise wheat and clover.

As we have to confide these institutions to men devoid of all the qualities which have rendered the influence exercised by Thaer at once so powerful and beneficent—as we have to choose them amongst men who possess other talents of which, in one point of view, Thaer was inferior to many practitioners, these schools have lost their scientific character; and their influence and their position have shown in an incontestable manner that practice alone—that is to say, without the aid of science—is quite incapable of making progress. Hence, we can comprehend the remarkable phenomenon of academies, often richly endowed by the State, not assisting during half a century in the development of agriculture. We certainly cannot accuse them of having left the theory and practice precisely at the same point to which Thaer brought it; but it is certain they did not comprehend the aim that great man had in view, and that it is impossible for them to learn it.

These academies lost much of the faculty of ascertaining and comprehending the importance of a scientific result, when the pressure of the want was felt for experimental institutions (*versuch stationen*) taken from the heart of agricultural societies, and even recruited from the circle of practical agriculture for the purpose of experimenting on the practical results of science, and thus enabling them to connect theory with practice. The existence of these experimental stations showed how little the agricultural academies were in a state to put the forces and means at their disposal to the service of progress, which is the most important of all causes. In fact, if from the commencement the schools had kept up their character, no one would have thought of building other institutions, half scientific and half practical. It is not, then, to be wondered at that opposition against the new scientific doctrines manifested itself in these schools, where the directors should at least have shown themselves friendly to them. But it is impossible for them to shine in their schools, nor even to keep pace with the scientific discoveries of the age, whilst they have a career open before them for giving proofs of their ability, of their agricultural knowledge, and acquiring for themselves reputation and honour in the estimation of their superior officers, by augmenting each year the produce of the establishment entrusted to their management.

A director, animated by a true scientific spirit,

would consider, under all circumstances, the interests of the school as being the most essential thing, and the revenue of the land as an element very accessory, and that ought to be found in every establishment for education.

From this false position proceeds again, the distance of agricultural academies from establishments for general instruction, which have almost entirely excluded from them instructions in natural history; and that has hindered them from participating in the extraordinary advancement made in the science of nature since the time of Thaer. One can scarcely picture to himself the difference which exists between the manner in which the most simple things were taught in those schools and the present state of scientific knowledge. We ought not, then, to be shocked to see the simplicity with which certain leaders of agriculture exhausted themselves, to show that the culture of the fields is not subject to the laws of nature, and that practice is a thing altogether separate—entirely different from head-knowledge, or that which is called "theory."

The men who entitle themselves "practitioner" have put forward, with immoderate enthusiasm, practice to the diminution of science. As long as the conquests of science extended over a limited circle, they passed unperceived; but as soon as its importance increased, it was incapable of appropriating them to itself. Then the right-thinking amongst the practical men acknowledged that the old way was insufficient, and that it had become necessary to open a new one for the advancement of progress.

At this time all the agricultural colleges have completely lost their importance, and if they are supported they will become the asylums of a number of professors who have forced themselves into a position which they are quite incapable of filling honestly; which is interdicted to them by the absence of the necessary faculties, and by failing of the acquirements they profess to teach. Indeed, a great number of men, who are incapable of finding the theoretical solution of the most simple problem put into practice, promise to us agriculturists to solve the most complicated questions of vegetable physiology and culture, by means of a recipe for the composition of a manure. Agriculture is a new country that science has to conquer, and which, when it comes to discover a new land, begins by falling into the hands of adventurers and swindlers. It is only recently that the true cultivators have arisen, who, by the sweat of their brow, have succeeded in the development of the natural riches of the country, and in drawing from it a portion of its resources. The period at which this transformation in agriculture will take place, is no longer at a remote distance, for we begin to comprehend that the agriculture of our times must renounce its prejudices, in virtue of which we thought it possible to succeed in husbandry with a less amount

of science than in all the other professions. The agriculturist sees that he must renounce the vague *perhaps*; that is to say, he cannot proceed in rational practice without possessing true knowledge and acquirements; that he need not fear compromising the results of his efforts and meditations by appropriating to himself what wise and experimental men have found by reflection, which they have left for the good of humanity; in fact that he ought not to be treated, in the lessons which are given him, as a child whom one makes to sit at a small table, and for whom one cuts small pieces for fear he should be choked by swallowing large pieces too quickly.

The golden age of equality in ignorance is past for agriculture; and we already see making its appearance amongst them a species of hierarchism, according to the state of their minds and the amount of knowledge they have acquired. Science is the force that conquers capital, and, consequently, power; it chases then, naturally and infallibly, the son from the heritage of his father.

The agriculturist or manufacturer who uses his eyes must certainly see that he lives in a cruel age, regardless of persons, which renders more and more difficult the subsistence of a man ignorant, incapable, or weak, and that in the generation following it will be altogether impossible. He must understand that he ought always to learn more; that in no period can he live quietly, or avoid taking part in the determined struggle of competition, and that all protection that hinders him from employing his forces and development only hastens his ruin.

The agriculturists' education would not have been directed for a long time in a different manner from that of other professions, if, instead of interfering in their affairs by the protection of schools of agriculture, the students had been left to seek their own means of instruction. It was, therefore, tacitly acknowledged that the agricultural student was uncultivated, ignorant, without education; that he needed particular means of instruction; and that academies of agriculture were calculated to hinder him from rising to a superior position. In our schools of commerce and manufacture (which did not exist in the time of Thaer) the agricultural student may acquire a much deeper knowledge of mathematics and natural history than by following the course of the academies of agronomy; as it teaches no political economy, nor chemistry, natural philosophy, nor even the science of botany, which is particularly useful to the agriculturist. The union of establishments, specially for their instruction, to the universities, is the most powerful means of supplying the wants of the agriculturists. Roscher considered that reunion as being much more important than an affiliation to a model establishment. If we enquire into the real state of these agricultural academies, we find they possessed a most miser-

able stock of implements, indeed of all machines and instruments for agriculture. The tools used for the purpose of teaching practical knowledge resembled those which come from England, or those which are in use in our great rural establishments, as the schools of brewing, distilling, vinegar, sugar, and starch making, which we find attached to these same academies, similar to the breweries, distilleries, and vinegar factories of our large towns, or rather to the manufacturing of sugar and starch in the country. The machines and apparatus are old—like child's toys; in fact all that the scholar can learn through their medium is what he cannot avoid learning when he enters on practical life. Even the best moral institutions that the State supports possess faults, which increase from year to year; because the stimulus of competition, so powerful to excite industrial progress, is altogether excluded from a public establishment.

The agricultural academies have outlived themselves, like the pharmaceutical colleges which flourished till about twenty-five years ago, and then were no more heard of. The apothecary needs as much scientific and practical knowledge as the agriculturist, but he no longer now, as formerly, goes into a special institute; he apprentices himself to an accomplished apothecary for some years, and then finishes his education at the university. That is the path that Thaer proposed to indicate to the agriculturists—the object that they would attain much better, and more surely without special academies. If the State would expend usefully the money that it throws away in keeping up these academies and model institutions, which are in reality but child's play, it would give the means, now unattainable, of instruction. By procuring models of implements and machines, and forming permanent exhibitions in our large towns, it would do more for the advancement of practice, than the establishing of the most perfect model school.

In every age, as now, our academical operations have been directed towards science. The only problem that a session of learned men can solve is the increase of human knowledge. The only use that the people in mass, or citizens in particular, draw from these discoveries depends exclusively on the people or individuals; in fact, those alone can participate in the triumphs of a scientific spirit who have succeeded in mastering it.

Consequently, the effect of the operations of an academy of science depends essentially upon the intellectual elements that the nation possesses—the facility with which it approximates to itself the knowledge presented to it, and causes it to fructify. It is the essential nature of any intellectual work whatever to increase the amount of knowledge gathered in the domain of any particular science, and to exercise an influence in a circle more or less extensive. In many cases this effect is produced immediately; in

others, on the contrary, it manifests itself only after a long course of years of changes, material or intellectual, in the situation of the human species. We know no means of measuring in advance the influence of a scientific work, and its value to the life of populations. Every great result has had a small beginning; every important discovery may be compared to the roots of the oak, which are so fine that they can scarcely be seen, but which must sustain a trunk, branches, and leaves before bearing flowers, and, still further, fruit. Millions of men taste the flavor of fruit without knowing what myriads of rootlets and leaves must work to extract from the soil the juices which fill them; many are even ignorant that without the aid of these innumerable agents the sterile tree would bear no fruit. Thus, like the different links of a chain, millions of discoveries precede the great results which are the fruits of the tree of science, and to which is attached the name of a discoverer whom the vulgar proclaim inventor. The smallest discovery, almost invisible when it bursts from the mind of the thinker, reaches maturity by the evolution of time, and thus arrives at the full development of the germs it contains. The most enthusiastic man would not have dared to predict, fifteen years ago, the influence that the ideas and researches of Sommering were destined to have over the incomes of men, nations, and ports of the world. Who would have been able to say that the discovery of new chemical preparations, possessed of the property of taking fire by collision, inaugurated a new epoch in the art of war? Could we divine that the works of Fraunhofer would exercise a useful influence over astronomy, and that thirty years would pass away before the salt of Glauber was applied to the fabrication of glass by the advice of Gehlen, and that the liquid glass invented by Fuchs would give birth to a new process of painting, and come into general use in the stereoscope? Each scientific result is an expression of the life of the soul; and it is in its nature to live for great things, just as the root gives birth to a complete organism.

### On the Commercial Value of Artificial Manures.

*Continued.*

My attention has been directed to a remarkable change which has of late years come over the minds of some manufacturers with regard to analyses and money valuations; many of those who were once much opposed to such proceedings are now most anxious to have recourse to them for certain manures. The reason for this anxiety is obvious; for if scientific men whose names are well known to the public at large, gravely state that manures which are actually sold at £7 10s., according to the usual mode of computing their value, are worth £11 10s., it is

but natural that manufacturers should desire to secure so favorable, though unreasonable, a testimony. For years I have refrained from putting a money value upon manures sent to me for manufacturers; for it strikes me very forcibly that if a maker has not sufficient chemical and commercial knowledge to determine correctly the money value of his own productions, he has mistaken his proper calling.

Although the trade in manures is getting more and more into the hands of a limited number of intelligent and large manufacturers, there are still to be found, here and there, small and ignorant makers, and farmers who make a few hundred tons of artificial manures for their own use and that their neighbours. Generally speaking, a manufacture carried out on such a limited scale brings no advantage to the consumer, and seldom benefits, for any length of time, the producer, who has neither skill, capital, or enterprise to compete with a firm which does a large trade. The price which a manufacturer has paid for his raw material, including labour, carriage, bags, &c., is not necessarily a criterion of the worth of the manure, because he may have bought under serious disadvantages. A man who has not sufficient chemical knowledge will often select raw materials which are very good in appearance, but, in reality, cannot be employed so profitably as others; or he may not have sufficient capital to buy in materials which can only be obtained by taking a ship's cargo at a time; or, if he has capital, he may not have sufficient commercial knowledge and decision to take advantage of a favourable turn in the market. For these and similar reasons such a dealer will lose money if he sells the manufactured products at a rate which will yield a good profit to another vendor more favourably circumstanced.

In commercial analysis and calculations founded upon them, the form and conditions of the several constituents are too often overlooked. This is especially the case with respect to the state of combination and mechanical condition in which the insoluble phosphates and nitrogens occur.

Insoluble phosphate of lime may be present in any of the following forms—One half, or one fourth inch bones, fine bone-dust, boiled bones, bone-black, bone-ash, coprolites, apatite, Estramadura phosphate, Sombrero guano, and phosphatic guanos.

Now, in most of these conditions insoluble phosphate of lime has a different commercial and agricultural value. One fourth-inch bones are more effective and cost more than one-half inch; fine dust is still more expensive; and, generally speaking, the fine bone-dust is the most powerful in its action and the greater the cost of preparation. When bones are acted upon by acid, but not applied in sufficient quantity to convert all the phosphate of lime which they contain in-

to soluble phosphate, there remains in the mixture a certain quantity of insoluble phosphate, which, in this condition, is still more valuable than in that of fine bone-dust. On the other hand, the insoluble phosphates in animal charcoal (bone black) and even bone ash are of very little use in a turnip manure. Of still less use to root crops, if possible, are the insoluble phosphates in coprolites, apatite, and other mineral phosphates. Intermediate in their action between fossil phosphatic materials and bones are, perhaps, certain semi-fossil guanos; whilst in Peruvian and several phosphatic guanos the insoluble phosphates are so extremely minutely divided that I am inclined to consider them worth twice as much as phosphates in the form of ordinary bone dust.

It is, therefore, simply absurd to put the same value on insoluble phosphates, irrespective of the form in which they occur, since in a turnip manure their worth may range from absolutely nothing up to £7, £8, or even £12 a ton.

As regards nitrogen, this element may be present in the shape of ammoniacal salt, or of nitrate of soda, or uric acid; or, again, in shoddy, whale blubber, fish refuse, horn and hide clippings, scutch, leather refuse, and many other forms. In all these different forms nitrogen has a different agricultural and commercial value, and it is therefore unreasonable to assume the same price in calculating the money value of the nitrogen which a manure may contain in so many varied shapes.

Besides this, some purely practical matters have to be well considered before a fair estimate can be given. In some instances superior composition in regard to ingredients may be more than neutralised by imperfect pulverisation or by a damp and lumpy condition, tending to inequality of distribution and irregularity in the growth of the crop. A fine state of division, dry condition, and uniformity of composition cannot be secured without a considerable increase in the cost of manufacture. No allowance, however, is generally made for this expenditure of money by our rule-of-three chemists; or, if anything at all is allowed, the same manufacturing expenses are assumed whether the manure be fine, dry, and uniform, or the reverse. It is just thereby done to honest and skilful manufacturers, and at their expense the sale of apparently cheap, but really inferior manures is encouraged. Is the manure dry enough to admit of equal distribution on the land?—is it very fine, or coarse and lumpy?—is it uniform in composition?—are the ingredients and their relative proportions in a manure really useful for the purpose for which the latter is recommended?—what facilities are there in a particular locality for procuring the required fertilisers?—and many similar questions that do not enter for a moment into the mind of a mere "calculating machine," requires to be well weighed before

anything like a just estimate of the money value of a manure can be given.

In a highly concentrated, well prepared super-phosphate, I have already noticed that soluble phosphate has a somewhat higher commercial value than in an ordinary sample. Concentration or dilution of all the more fertilising constituents similarly affects the commercial value of other manures. It is, therefore, evidently unfair to take as a standard the price at which ammonia, phosphate &c., can be purchased in Peruvian guano, in calculating the money value of night-soil, sewage, and other bulky fertilisers.

A very striking example, showing how much bulky and, comparatively speaking, valueless materials reduce the money value, is presented to us in farm-yard manure. One ton of fresh yard manure of fair average quality, I find, contains :

|                                                                  | s. | d.  |
|------------------------------------------------------------------|----|-----|
| 6½ lb. of soluble phosphate of lime, worth, at 3d. per lb., ..   | 1  | 7½  |
| 8½ lb. of insoluble phosphate of lime, worth, at 1d. per lb., .. | 0  | 8½  |
| 15½ lb. of potash, worth, at 3d. per lb., ..                     | 3  | 1½  |
| 15 lb. of ammonia, worth, at 6d. per lb., ..                     | 7  | 6   |
| Total, .. .. .                                                   | 12 | 11½ |

Whilst thus the calculated value of farm-yard manure is nearly 13s. per ton, its real commercial value is about 5s. per ton.

Again, before certain measures could be obtained that are now specially prepared to suit particular soils, or particular crops, enterprising and intelligent manufacturers have frequently incurred heavy expenses in trying all kinds of fertilising mixtures before they succeeded in ascertaining the states of combination and the relative proportions in which these should be combined in order to produce the best practical results. It is, therefore, but fair that those who profit by these researches should repay the manufacturer for the time, skill, and expense which he has bestowed upon the production of such special manures. In estimating the money value of such fertilisers this ought to be taken into consideration, and allowance be made for more than mere market price of the several uncombined ingredients.

Perhaps it may be suggested that all these observations only tend to show the inability of the chemist to give a reliable estimate of the money value of a manure. I openly confess concurrence in this sentiment if the name of "chemist" is applied to a mere human analysing and calculating machine, or even to a purely theoretical man of science; but strongly repudiate it if it indiscriminately refers to every chemist.

The errors committed by purely theoretical men, from the carelessness and ignorance of others who call themselves agricultural chemists, show incapacity in individuals; but they do not prove that men who, without presumption, may lay claim to the office of an agricultural chemist, are

not in a position to render most useful services to the farmer by informing him whether manures sent for examination are cheap, dear, or moderate, at the prices at which they are offered for sale. Unquestionably, a considerable amount of commercial and agricultural knowledge, as well as judgement and the fixed determination neither to favour producer or consumer, are quite as essential qualifications in an agricultural chemist as analytical skill; but those agricultural chemists who possess the somewhat rare gift of uniting sound and scientific knowledge with good sense and acquaintance with practical matters assuredly are, or ought to be, in the very best position properly to estimate the agricultural and money value of manures.—*Journal of Royal Agricultural Society of England.*

## Horticultural.

### Flower Garden and Pleasure Grounds.

A friend remarked to us after the issue of our last number, that it was very discouraging to be told that ten per cent. on the original cost should be the estimated cost of maintaining a place after its completion. He thought if that were generally known, it would prevent many from entering on country life. "My place," said he, "cost me about \$20,000, and I should be sorry to believe that I had to spend \$2,000 annually to maintain it in decent order." As our friend's place embraces but five acres, we were surprised at the cost, but found he included *his house* in the sum named. Allusion is again made to the subject as other parties may have misunderstood our remarks. We referred simply to the *garden and its embellishments*. Those few places in the Union that have had \$20,000 spent on pure gardening, will not find \$2,000 too high an estimate for their annual maintenance, and never ought to find in that fact any discouragement.

From remarks made by other friends, we learn that the observations offered on this subject have attracted considerable attention. We are pleased that they have done so. Gardening suffers no greater injury from any source than from parties who go ignorantly into its pursuit; and we can do both it and the citizen proposing to go into the country, no greater favor than to show plainly what gardening costs, as well as indicate the various ways in which pleasure may be derived from it.

Planting of spring bulbs, tulips, hyacinths, crocus, snowdrops, fritillarias, lilies, etc., and the transplanting of shrubs and division of herbaceous plants, will occupy chief attention in October. All herbaceous plants are much better for being protected through winter by a covering of dry leaves, on which a little soil is thrown to keep the leaves from blowing away. Half-

hardy roses and vines may be protected in the same way. When they are very long and slender they are taken down from their trellises, and coiled into circles as small as may be without risk of breaking them, and then the soil put on. Those things that grow late, such as many kinds of Noisette roses, should have their immature top shoots shortened a few weeks before the protecting process is commenced. The wound will then heal over, and not cause the decay of the upper portion of the shoots, as is very often the case when they are either cut at laying down, or not shortened at all.

Of course, those roots that suffer by frost should be taken up before danger. Gladiolas, Madeira vines, dahlias, tuberoses, etc., for instance.

Towards the end of the month almost all kinds of tree seeds may be sown, except pine, unless there is any danger from mice or other vermin. It is, on the whole, best as soon as the seeds are at hand, to place them in boxes with more than an equal bulk of sand, and set them out to the weather to freeze. They must be sown out in the spring as early as the ground will work.—Some seeds will not germinate till the second year. If they do not appear early in the season, they should not be disturbed. Many seeds that usually come up the season after sowing, will not do so if the shells are allowed to dry and harden first. Cherries, peaches and most fruits, will often lie so, and halesias roses and thorns, occasionally stay three years. Seed-beds should be selected in a deep, warm and rich soil; and one tolerably free from the seed of weeds, on any other it will not pay to raise seedlings. In States where the frosts are severe, seedlings of all kinds that have not attained a greater height than six inches, should be taken up, "laid in" in a sheltered place thickly, and covered with anything that will keep frozen during the winter. If left out they are liable to be drawn out and destroyed. Young seedling stock received from a distance, should be also so treated. In the more Southern States they may be set out at once, and as much planting as possible be accomplished that will save spring work. Many cuttings will not do well unless taken off at this season and laid in the ground under protection, like seedlings, the quince, syringas, or lilacs, *spirea prunifolia*, and some others. In the "mild winter States," evergreen cuttings should be made now, and set out thickly in rows. The leaves need not be taken off, but short, thickest branches laid in under the soil. When rooted next fall they may be taken up and divided into separate plants. In more Northern States, evergreens may not be so struck at this season, unless protected by green-houses and frames.—Where these are at hand, evergreens may be put in, in boxes or pans all through the winter.

—*Gardener's Monthly*.

## Transactions.

### Prize List, Provincial Exhibition.

(Concluded from last number.)

#### CLASS XXXIII.—PLANTS AND FLOWERS.— (147 Entries.)

*Judges*.—Geo. Sheppard, Montreal; Geo. Laing, Hamilton; John Gray, Toronto; Wm. Grey, Woodstock.

Best dozen Dahlias, named, Geo. Leslie, Toronto, \$2; 2d do do, John Brown, Toronto, \$1 50; 3d do do, Judge Harrison, Toronto, \$1.

Best and largest collection of dahlias, Geo. Leslie, Toronto, \$5.

Best bouquet of cut flowers (for table), Geo. Vair, Yorkville, \$2; 2d do, Judge Harrison, Toronto, \$1 50; 3d do, W. A. F. Currie, Niagara, \$1.

Best hand bouquet, Jas. Fleming, Toronto, \$2; 2d do, J. M. Hirschfelder, Toronto, \$1 50; 3d do, Geo. Vair, Yorkville, \$1.

Best collection of green-house plants, not less than 12 specimens in flower, Judge Harrison, Toronto, \$10; 2d do, H. Eccles, Toronto, \$6; 3d do, Sam Ashby, Toronto, \$4.

Best 12 pansies, Jas. Best, Ashport, \$2; 2d do, H. Eccles, Toronto, \$1 50; 3d do, Chas. Arnold, Paris, \$1.

Best 6 fuchsias, in flower, Christopher Young, Yorkville, \$4; 2d do, H. Eccles, Toronto, \$3; 3d do, Sam Ashby, Toronto, \$2.

Best collection of annuals in bloom, Jas. Forsyth, Toronto, \$2; 2d do, R. Guthrie, Toronto, \$1 50; 3d do, Joshua Norrish, Eden Mills, \$1.

Best 6 cockscombs, W. A. F. Currie, Niagara, \$2; 2d do, Geo. Vair, Yorkville, \$1 50; 3d do, Edward Lewis, Yorkville, \$1.

Best 6 balsams in bloom, S. Ashby, Toronto, \$2; 2d do, do, do, \$1 50.

Best collection of asters, Jas. Fleming, Toronto, \$2; 2d do, Mrs. M. Choate, Port Hope, \$1 50; 3d do, R. C. Gill, Colborne, \$1.

Best collection of 10 weeks' stock, Hon. W. Cayley, Toronto, \$2; 2d do, R. C. Gill, Colborne, \$1 50; 3d do, Chris. Young, Yorkville, \$1.

Best collection of hybrid perpetual roses, not less than 12 blooms, Judge Harrison, Toronto, \$3; 2d do, H. Girouard, Hamilton, \$2.

Best floral ornament or design, J. M. Hirschfelder, Toronto, \$5; 2d do, J. M. Hirschfelder, Toronto, \$4; 3d do, W. T. Goldsmith, Toronto, \$3.

Best collection of verbenas, not less than 12 varieties, John Brown, Toronto, \$3; 2d do, Jas. Forsyth, Toronto, \$2; 3d do, Geo. Vair, Yorkville, \$1.

Best 6 petunias, Rev. E. Baldwin, Toronto, \$2; 2d do, Geo. Leslie, Toronto, \$1 50; 3d do, J. M. Hirschfelder, \$1.

Best collection perennial phloxes, George Leslie, Toronto, \$2.

Best 6 hardy shrubs, spikes in flower, Jas. Forsyth, Toronto, \$2; 2d do, Geo. Leslie, Toronto, \$1 50; 3d do, H. Girouard, Hamilton, \$1.

Best collection of hollyhocks, J. C. Small, Toronto, \$2; 2d do, Chris. Young, Yorkville, \$1.

Best display of plants in flower, distinct from other entries, Chris. Young, Yorkville, \$10; 2d do, J. M. Hirschfelder, Toronto, \$6.

Best collection of native plants, dried and named, Wm. Saunders, London, \$5; 2d do, Mrs. C. P. Traill, Peterborough, \$3.

Best specimen of useful and ornamental rustic work for the garden, H. Girouard, Hamilton, \$4.

EXTRA PRIZES.—J. M. Hirschfelder, Toronto, collection of Petunias and foliage plants, \$1 50. Richard Guthrie, Toronto, collection of perennial and biennial flowers, \$1 50. Geo. Leslie, Toronto, collection of herbaceous flowers, \$1 50. Mrs. M. A. Choate, Port Hope, wreath and bouquet of everlasting flowers, \$1 50. John Gray, Toronto, perennial phloxes, \$1. John Gray, Toronto, collection of seedling perennial phloxes, 15 varieties, \$2. Ezekiel Snider, Brockville, bouquet of everlasting flowers, \$1. Samuel Ashby, Toronto, orange tree, \$1 50. Bruce & Murray, Hamilton, collection of gladioli, \$1 50. James Fleming, Toronto, collection of zinnias, \$1 50.

#### CLASS XXXIV.—DAIRY PRODUCTS AND PROVISIONS.—(128 Entries.)

*Judges.*—M. Thwaite, Whitby; Trueman McEvers, Cobourg; Samuel Lake, Newburgh; Wm. Smith, Frankville; E. C. Fisher, Etobicoke.

Best firkin of butter, in shipping order, not less than 56 lbs., P. R. Palmer, Thurlow, Hastings, \$12; 2d do, Ann Youart,

Nassagaweya, \$10; 3d do, Samuel Wood, Islington \$8; 4th do, Arch. Glendinning, Ellesmere, \$6.

Best butter, not less than 28 lbs, in firkins, crocks or tubs, James Patton, Markham, \$8; 2d do, Mary Thomson, York Tp., \$6; 3d do, Henry Jennings, Victoria Sq., \$4; 4th, do, Ann Youart, Nassagaweya, \$2.

Best cheese, not less than 30 lbs, W. R. Dorn, Napanee \$10; 2d do, Hugh McMillan, Erin, \$8; 3d do, James Patton, Markham, \$6; 4th do, P. R. Palmer, Thurlow, \$4.

Best two stilton cheeses, not less than 14 lbs. each, Hiram Ranney, Dereham, \$10; 2d do, do, do, \$8; 3d do, H. K. Parsons, Guelph, \$6; 4th do, Hiram Ranney, Dereham, \$4.

Best honey, in the comb, not less than 10 lbs, Thos. Greenhaugh, Brampton, \$3; 2d do, James Lesslie, York Tp., \$2; 3d do, Hugh McKee, Norwichville, \$1 50; 4th do, Robert Anderson, York Tp., Transactions.

Best jar of clear honey, Hugh McKee, Norwichville, \$4; 2d do, John Muir, Scarborough, \$2; 3d do, Robert Anderson, York Tp., \$1 50; 4th do, Wm. Jackes, Eglinton, Trans.

Best side of cured bacon, F. W. Fearman, Hamilton, \$3.

Best ham, cured, F. W. Fearman, Hamilton, \$3; 2d do, do, F. W. Fearman, Hamilton, \$2; 3d do, Jonas S. Barnes, St. Thomas, \$1.

EXTRA PRIZES.—Pine-apple cheese, Hiram Ranney, Dereham, \$2. Cured meats, Benj. S. Morris, Toronto, \$1. Tin of lard, Benj. S. Morris Toronto, \$1. Jar of prepared honey, John McKee, Norwichville, \$1. Two pieces of breakfast ham, F. W. Fearman, Hamilton, \$1. Two pieces of breakfast bacon, F. W. Fearman, Hamilton, \$1.

NOTE BY JUDGES.—Practical information of the mode of making pine-apple cheese should be required and published in the *Journal of the Board of Agriculture*.

#### AGRICULTURAL IMPLEMENTS.

##### CLASS XXXV.—IMPLEMENTS WORKED BY HORSE OR OTHER POWER.—(186 Entries.)

*Judges.*—J. Bingham, Norwich; John Tennant, Paris; John N. Diamond, Belleville; Wm. Woods; E. C. Fisher, Etobicoke.

Best iron plough, Wm. Mahaffy, Brampton, (draught on trial 466 lbs.) diploma and \$12; 2d do, Edward Wilmott, Kingston,

draught on trial 520 lbs.) \$8; 3d do, Hugh Masson, Ottawa, (draught on trial 558 lbs.) \$4.

Best wooden plough, Wm. Mahaffy, Brampton, (draught on trial, 441 lbs.) diploma and \$12; 2d do, Isaac Modeland, Brampton, (draught on trial 493 lbs.) \$8; 3d do, Hugh McLaren, Lowville, (draught on trial 489 lbs.) \$4.

Best subsoil plough, Peter Mallaby, Weston, diploma and \$12; 2d do, Atkinson Bros., Thistleton, \$8.

Best double shear trench plough, Richard Hill, Port Hope, \$10; 2d do, H. A. Massey, Newcastle, \$6.

Best double mould plough, Wm. Jeffrey Thornhill, \$10; 2d do, Peter Mallaby, Weston, \$6.

Best pair of harrows, Pet Mallaby, Weston, \$6; 2d do, Wm. Mahaffy, Brampton, \$4; 3d do, Geo. Prentice, Columbus, \$2.

Best horse power thresher and separator, John Abel, Woodbridge, diploma and \$20; 2d do, Joseph Hall, Oshawa, \$12; 3d do, Haggart Bros., Brampton, \$8.

Best grain drill, Maxwell and Whitelaw, Paris, diploma and \$12; 2d do, Jas Atkinson, Woodbridge \$8; 3d do, Robt. Fidell, Queensville, \$4.

Best straw cutter, Maxwell and Whitelaw, Paris, \$5; 2d do, Geo. C McKenzie, Georgetown, \$4; 2d do, Hugh McLaren, Lowville, \$3.

Best smut machine, Jno. Gartshore, Dundas, \$6.

Best portable grist mill, H. A. Massey, Newcastle, \$12.

Best grain cracker, Ganson Waterous & Co., Brampton, \$8; 2d do, Jacob Lawrence, Palermo, \$6; 3d do, Alanson Harris, Beamsville, \$4.

Best corn and cob crusher, Ganson Waterous & Co., Brantford, \$4.

Best cider mill and press, Alanson Harris, Beamsville; \$12; 2d do, N. M. Samson, St. Catharines, \$8.

Best two horse waggon, I W. Weber, Conestoga, \$12; 2d do, Jno. Marshall, Brampton, \$8; 3d do, James Berry, Wellington Square, \$4.

Best one horse light market waggon, Sam. Lake, Newburgh, \$10; 2d do, Henry Pearin, Stanley Mills, \$7; 3d do, Shuttleworth & Mallaby, Weston, \$3.

Best horse rake, Alanson Harris, Beamsville, \$4.

Best metal roller, Atkinson Bros., Thistleton, \$11; 2d do, H. A. Massey, Newcastle, \$8.

Best wooden roller, Salem Eckhardt, Unionville, \$10; 2d do, Andrew C. Bruce, Glenmorris, \$5.

Best stump extractor, Hugh McLaren, Lowville, \$8.

Best reaping machine, Isaac Modeland, Brampton, diploma and \$20; 2d do, Collins & Osborne, Guelph, \$12.

Best Mowing machine, R. & R. S. Patterson, Belleville, diploma and \$20; 2d do, W. H. Walbridge, Belleville, \$12; 3d do, do, \$8.

Extra prize, a one horse mowing machine, W. H. Walbridge, Belleville, \$10.

Best combined mower and reaper, R. & R. S. Patterson, Belleville, diploma and \$20; 2d do, W. H. Walbridge, Belleville, \$12; 3d do, Collins & Osborne, Guelph, \$8.

Best field or two-horse cultivator, T. & G. Morgan, Markham, \$12; 2d do, Joshua Carlton, Toronto, \$8; 3d do, Salem Eckhardt, Unionville, \$4.

Best horse hoe, or single horse cultivator, Henry Collard, Gananoque, \$4; 2d do, George Prentice, Columbus, \$3.

Best machine for sinking field drains and laying in and covering tiles, Jas. Chase, Brooklyn, \$60.

Best portable steam engine, for agricultural purposes, 6 to 10 horse power, Thomas Zealand, Port Hope, \$50; 2d do, F. G. Beckett & Co., Hamilton, \$30; 3d do, Ganson, Watrous & Co., Brantford, \$20.

Best improved liquid manure drill, for drilling two or more rows of liquid, with turnips, mangels, &c., either on the ridge or flat, Emanuel Rocky, Salem, Co. Elgin, \$25; 2d do, James Berry, Wellington Square, \$15.

EXTR PRIZES.—One cross cut sawing machine, J. & S. Nixon, Ingersoll, \$4. Cast iron beam plough. Jos. Fleury, Aurora, \$3. Ribbing plough, do, do, do, \$2. Side hill plough, do, do, do, \$2. Grain cultivator and sower, Jas. Hamilton, Peterboro, \$3; Combined clover thresher and huller, Jos. Hall, Oshawa, \$5. Clover and Timothy seed sower, Emanuel Rocky. Salem, Elgin, \$2. Sod and subsoil plough, Whittemore, Belcher & Co., Massachusetts, \$2. Cultivator adapted for the cultivation of new land, or land encumbered with obstructions, which cannot ordinarily be ploughed, John A. Cull, Toronto, \$6.

**REMARKS BY JUDGES.**—The Judges in this class would call the attention of the Board to the fact that our field of labor is too great for us to be able to do justice to ourselves and the competitors, for the want of time. We therefore recommend that in future there shall be another set Judges for ploughs. We would also call the attention of the Board to the fact that we found the wooden and iron harrows were competing together in one section, when they should be in two distinct sections.

**CLASS XXXVI.—AGRICULTURAL TOOLS AND IMPLEMENTS, CHIEFLY FOR HAND USE.—**  
(142 Entries.)

**Judges.**—Geo. Davison, Kingston; Robert Alexander; C. Yale, St. Catherines; W. Gibbard, Napanee.

Best fanning mill, Thomas Wilson, Richmond Hill, diploma and \$6; 2d do, O. W. Everett, Dundas \$4; 3d do, Charles Bodly, Mt. Forest, \$2.

Best seed drill, or barrow, Emanuel Rockey, Salem, Elgin, \$4; 2d do, Thomas Penton Paris, \$3; 3d do, Geo. Young, Concord, \$2.

Best straw cutter, G. C. McKenzie, Georgetown, \$5; 2d do, Maxwell & Whitelaw, Paris, \$4; 3d do, Hugh McLaren, Lowville, \$3.

Best machine for cutting roots for stock, M. Cant, Galt, \$6; 2d do, John Leigh, Aurora, \$4; 3d do, Maxwell & Whitelaw, Paris, \$2.

Best cheese press, Joel Hughes, jr., Schomberg, \$8; 2d do, And. Boyle, Eden Mills, \$6.

Best churn, Jesse Kinney, Brantford, \$3; 2d do, Nathan Campbell, Stratford, \$2.

Best garden, walk, or lawn roller, H. A. Massey, Newcastle, \$4.

Best farm gate, Chris. Doner, Cashel, \$3; 2d do, Wm. Depew, Simcoe, \$2.

Best specimen farm fence, of wood, Samuel Hall, Toronto, \$3; 2d do, David Fleming, Toronto, \$2.

Best specimen wire fencing, not less than two rods, erected on the ground, W. & Thos. Walker, Brampton, \$8.

Best wooden pump, Peter Kribbs, Stouffville, \$4; 2d do, C. W. Card, Brooklin, \$3.

Best half dozen hay racks, A. P. Busseck, Stouffville, \$3; 2d do, Thomas Bryan, jr., London, \$2; 3d do, do, do, \$1.

Best half-dozen manure forks, A. S. Whiting, Oshawa, \$3.

Best half-dozen hay forks, A. S. Whiting, Oshawa, \$4.

Best ox-yoke and bows, John Baker, Waterdown, \$2; 2d do, John Ramsay, Eden Mills, \$1; 3d do, Platt Hinman, Grafton, Trans.

Best grain cradle, J. B. Lazier, Port Perry, \$2; 2d do, Richard Sylvester, Ellesmere, \$1.

Best half-dozen steel hoes, A. S. Whiting, Oshawa, \$3.

Best half dozen grass scythes, A. S. Whiting, Oshawa, \$3.

Best half-dozen cradle scythes, A. S. Whiting, Oshawa, \$3.

Best machine for making drain tiles, W. Hamilton & Son, diploma and \$30,

Best assortment of drain tiles, Thomas Nightingale, Yorkville, \$6; 2d do J. Brown, Carleton West, \$4; 3d do, John Snowball, Markham, \$2.

**EXTRA.**—Assortment of drain tiles, shown by Wm. Gibb, Yorkville, erroneously entered, and not seen by judges of this class; prize awarded by revision committee in consideration of their excellent quality, equal to first, \$6 and Diploma.

Best straw fork, of wood, Thomas Moore, Etobicoke, \$2.

Best 6 chopping axes, Ellis Burrill, Belleville, \$3.

Best set horse shoes, W. Stephenson, Nasagaweya, \$2; 2d do, W. Mahaffy, Brampton, \$1.

**EXTRA PRIZES.**—Weed cutter, Samuel Cummer, Willowdale, \$1. Separator for grain, Chappell & Sprague, Rochester, N. Y., \$3. Grain Separator, John Gartshore, Dundas, \$3. Screw tobacco press, John Thomas, Hamilton, \$2. Grain shipping cart, Wm. Smith, Toronto, \$2. Ornamental Gate, Christopher Doner, Cashel, \$2. Assortment of horse shoes of various kinds, for diseased feet, Alex. Dunbar, London, \$4. Machine for facilitating churning, Thos Head, Cope-town, \$2.

**NOTE.**—A case of edge tools, grass scythes, drawing knives, chopping axes, &c., shown by J. W. Robinson, Co. Hastings, not entered, highly commended.

**CLASS XXXVII.—PREPARED CATTLE FOOD, ARTIFICIAL MANURES, &c.—**(3 Entries.)

**Judges.**—Hugh Ross, Kingston; P. R. Palmer, Thurlow.

Best ground bones for manure, P. R. Lamb, Toronto, \$4; 2d do, do, do, \$2.

Best specimen of other artificial manure?  
Thomas Martindale, York, G. R., \$4.

## ARTS AND MANUFACTURES DEPARTMENT.

COMPETITION OPEN TO CANADIAN EXHIBITORS ONLY.

CLASS XXXVIII.—CABINET-WARE AND OTHER WOOD MANUFACTURES—(61 Entries.)

*Judges.*—George Stephens, Cobourg; George Jackson, Simcoe.

Best bed room furniture, set of, Jacques & Hay, Toronto, \$10; 2d do, do, do, \$8.

Best centre table, do, do, \$7.

Best drawing room sofa, do, do, \$7.

Best drawing room chairs, set of do, do, \$7.

Best wardrobe, do, do, \$5; 2d do, do, do, \$4.

Best Cooper's work, Coridon Lewis, Salford, \$4; 2d do, R. S. Dodd, Stratford, \$3.

Best curled hair, 10 lbs., Peter R. Lamb, Toronto, \$3; 2d do, do, do, \$2.

Best handles for tools for carpenters, blacksmiths, gunsmiths, watchmakers, &c., collection of, Thomas Moore, Etobicoke, \$8.

Best joiner's work, assortment of, Smith & Burke, Toronto, \$8.

Best machine wrought moulding and flooring, 100 feet of each, do, do, \$6.

Best turning in wood, collection of specimens, Jacques & Hay, Toronto, \$6; 2d do, Smith & Burke, Toronto, \$4.

Best veneers, from Canadian woods, W. Clements, Newbury, \$10; 2d do, T. F. Purdy & Brother, Newbury, \$6.

Best wash tubs and wooden pails, three of each, factory made, Coridon Lewis, Salford, \$4.

EXTRA PRIZES.—Ker & Brother, Streetsville, samples of jack spools and bobbins for woollen and cotton mills, \$2. P. T. Ware & Co., Toronto, three sewing machine cases, \$3. William and Thomas Walker, Brampton, washing machine, \$2. O. W. Everett, Dundas, lot of turned wooden bowls, \$2. Richmond & Walton, London, Clothes dryer, \$4. Henry Fryatt, Aurora, scrubbing machine, commended. Thomas McMurchy, Glenwilliam, Patent Mangle, \$3. John Addison, Hamilton, patent spring Mattress, Diploma. James Meyers & Son, Toronto, washing machine and wringer, \$2. Harris, Brothers, Toronto, corn brooms, \$1. Samuel Creighton, Toronto, spinning wheel, \$2.

Michael Malcolm, Toronto, Chess Boards, comm'd. Wm. Haines, Toronto, specimens of varnishing and polishing on grand piano, \$4.

CLASS XXXIX.—CARRIAGES, SLEIGHS, AND PARTS THEREOF.—(51 Entries.)

*Judges.*—James Kay, Galt; John King, St. Thomas.

Best bent shafts, half a-dozen, A. P. Bussick, Stouffville, \$3; 2d do, Abraham Efner, London, \$2.

Best buggy, double seated, C. F. Hall, Toronto, \$8; 2d do, do, do, \$6.

Best buggy, single seated, Macabe & Co., Hamilton, \$7; 2d do, C. F. Hall, Toronto, \$5.

Best carriage, two horse, pleasure, C. F. Hall, Toronto, \$12; 2d do, do, do, \$8.

Best carriage, one horse, pleasure, Macabe & Co., Hamilton, \$8; 2d do, C. F. Hall, Toronto, \$6.

Best child's carriage, John Webster, Yorkville, \$4; 2d do, Edward Colley, St. Mary's \$3.

Best hubs, two pairs of carriage, Abraham Efner, London, \$3.

Best rims or felloes, two pairs of carriage, R. McKinley & Co., St. Catharines, \$3; 2d do, Abm. Efner, London, \$2.

Best spokes, one dozen, machine made, carriage, Thos. C. Saunders, St. Catharines, \$3.

Best two horse pleasure sleigh, Hart & Son, Picton, \$10.

Best sleigh, one horse, pleasure, Samuel Lake, Newburgh, \$8; 2d do, Macabe & Co., Hamilton, \$6.

Best springs, one set of steel carriage, Isaac Briggs, Gananoque, \$4; 2d do, Moria Spring Co., Belleville, \$3; extra do, buggy springs, John Stephenson, Unionville, \$2.

Best wheels, one pair of carriage (unpainted), C. F. Hall, Toronto, \$4.

EXTRA PRIZES.—W. J. Hamilton, Homer, Lincoln, trotting buggy, \$2. Do, do, trotting sulky, \$1. R. McKinley & Co., St. Catharines, bows for carriage tops, \$1. Do, do, rails for buggy seats, \$1. Do, do, set of bent sulky felloes, \$1. Do, do, set of cutter stuff, \$1. Do, do, bent stuff and bendings for cutters, \$2. John Webster, Yorkville, Express waggon, \$3. A. P. Bussick, Stouffville, sleigh bends, \$2. Abraham Efner, London, bent cutter and sleigh stuff, \$1. C. F. Hall, Toronto, Boston chaise, \$2.

**CLASS XL.—CHEMICAL MANUFACTURES AND PREPARATIONS.—[51 Entries.]**

*Judges.*—H. Y. Hind, Toronto; Thomas J. Cottell, Woodstock; T. Mellwraith, Hamilton; W. N. Alger, Brantford.

Best Glue, 14 lbs., Peter R. Lamb, Toronto, \$3; 2d do, do, do, \$2.

Best medicinal herbs, roots and plants, native growth, Dr. D. W. Poole, Norwood, \$12; 2d do, W. Saunders, London, \$8.

Best oils, linseed and rape, and other expressed kinds, Robert Pomeroy, Toronto, \$6.

Best oil (coal, shale or rock) Petrolia Refining Co., Petrolia, \$6; 2d do, T. W. Esmonde, Toronto, \$4.

Miss Kirkpatrick, Kingston, Ferns in India ink, \$2.

REMARKS BY JUDGES.—The Judges have found great difficulty in performing their duties in a manner satisfactory to themselves from the defective arrangement of the specimens. Many have not been seen at all. They would recommend that the persons in charge of the departments should be instructed to place sections as much as possible together. The judges have much pleasure in remarking that a decided improvement is observable in the fine arts department.

CLASS XLIII.—GROCERIES AND PROVISIONS—(77 Entries.)

*Judges.*—F. W. Fearman, Hamilton; D. McLaren, Mitchell; E. A. McNaughton, Newcastle.

**EXTRA ENTRIES.**—Black cassimere from merino wool, Barber Bros. Streetsville, \$4. Oxford grey, Barber Bros. Streetsville, \$4. Children's stockings, J. G. Crane, Ancaster, \$1. Overcoat of English material, Lawson & Co., Toronto and Hamilton, \$1. Overcoat of Canadian cloth, Lawson & Co., Toronto and Hamilton, \$1. Sheepskin mats, John Cooke, Toronto, \$1. Oxford doeskins, Barber Bros. Streetsville, \$3.

**NOTE BY JUDGES.**—The colours of the factory made flannels need improving. Some

of the home-made flannels to which we have not awarded prizes are very good, but the patterns are objectionable. The patterns of some of the woollen cloths and tweeds are also bad. An assortment of gentlemen's woollen scarfs from the Ontario Mills, Cobourg, is very good. A bale of factory cotton, manufactured by Gordon & McKay, is highly deserving of commendation.

#### CLASS LIV.—FOREIGN MANUFACTURES.— (39 Entries.)

**Judges.**—Dr. Beatty, Cobourg; Dr. Craigie, Hamilton.

Assortment of fishing hooks, fishing tackle, needles, &c. &c., Allcock, C. Laight & Co. Redditch, England, diploma.

Steam fire engine, Silsby, Myndesse & Co., Seneca, N. Y., diploma.

Patent saponifier, and soap manufactured therefrom, Erastus Burnham, Toronto, diploma.

Assortment of Steinway & Son's, Stodart's, and Chickering's pianos, exhibited by A. & S. Nordheimer, Toronto; commended as first class instruments of the respective manufacturers.

#### AMATEUR MUSICAL BANDS.—(2 Bands in competition.)

**Judges.**—G. M. Strathy, Mus. Doc. Toronto; Prof. F. M. Sofge, Toronto; W. L. Lawrason, London.

Best Canadian, amateur band, consisting of not less than eight performers, of whom there shall not be more than two professional artists, Cobourg brass band, \$60; 2d do, Union brass band, Toronto, \$40.

**NOTE.**—The Judges would suggest an Overture being made one of the pieces to be played in future competitions.

### Miscellaneous.

**INFLUENCE OF NATURE AS WE GROW OLDER.**  
—But there is a deeper truth than all this, in the influence which nature gains over us in proportion as life withdraws itself from struggle and contention. We are placed on earth for a certain period to fulfil, according to our several conditions and degrees of mind, those duties by which the earth's history is carried on. Desk and warehouse, factory and till, forum and senate, schools of science and arts, arms and letters, —by these we beautify and enrich our common habitation; by these we defend, bind together, exalt, the destinies of our common race. And

during this period the mind is wisely fitted less to contemplate than to act—less to repose than to toil. The great stream of worldly life needs attrition along its banks in order to maintain the law that regulates the movement of its waves. But when that period of action approaches towards its close, the soul, for which is decreed an existence beyond the uses of earth—an existence aloof from desk and warehouse, factory and till, forum and senate, schools of science and art, arms and letters,—gradually relaxes its hold of former objects, and, insensibly, perhaps, to itself, is attracted towards the divine source of all being, in the increasing witchery by which nature, distinct from man, reminds it of its independence of the the crowd from which it begins to re-emerge. And, in connection with this spiritual process, it is noticeable how intuitively in age we turn in strange fondness to all that is fresh in the earliest dawn of youth. If we never cared for little children before, we delight to see them roll in the grass over which we hobble on crutches. The grand-sire turns wearily from his middle-aged careworn son to listen with infant laugh to the prattle of an infant grandchild. It is the old who plant young trees; it is the old who are most saddened in autumn, and feel most delight in the returning spring. And, in the exquisite delicacy with which hints of the invisible eternal future are conveyed to us—may not that instinctive sympathy with which life rounds its completing circle towards the point at which it touches the circle of life winding up to meet it be a subtle intimation that, from such point of contact, youth will spring forth again? May there be no meaning more profound than the obvious interpretation, in the sacred words, "Make yourselves as little children, for of such is the kingdom of heaven?"—*Sir E. Bulwer Lytton.*

**TABLE TURNING FIFTEEN HUNDRED YEARS AGO.**—In the curious work of De l'Ancre, *L'incrédule et mescreance du Sortilege* (4to, Paris, 1622, page 236), is an account of two magicians, Patritius and Hilarius, who lived in the reign of Valens. Describing their proceedings, he says: "They prepared an enclosure of branches of laurel, in the same form as was at the tripod of Delphi. And, after having pronounced many charms, both by day and by night, they caused that a round table surrounded by this inclosure should turn itself and move (*se contournait et remuoit*) according to the matter they might require." It would occupy too much space to give the whole of the ceremonies; the result of the incantation, however, was, that the letters T. H. E. O. D. were exhibited, and said to be a portion of the name of Valens's enemy, and the emperor in consequence took care that Theodorus should not be put to death. This was the circiter A. D. 373.—*Notes and Queries.*

## Agricultural and Veterinary Instruction

A CLASS will be formed in Toronto for instruction in the Principles of Agriculture, and the Veterinary Art, specially adapted to the wants of young men engaged in, or intended for agricultural pursuits.—Professor Buckland will be assisted in the department of Scientific Agriculture by the Professors of Chemistry, Geology and Natural History in University College.—Mr. A. Smith, Licentiate of the Edinburgh Veterinary College, and consulting Surgeon to the Board of Agriculture for UPPER CANADA, will have charge of the Veterinary department.

The course will commence on *Wednesday, January 21st*, 1863, and continue for about six weeks. Three Lectures a day, and *no fees*.—The subjects treated of will comprise:—

The History, Breeding, Diseases, and Treatment of Farm Animals,—including their Anatomy and Physiology, with a course of instruction in Practical Dissecting.

Agriculture in its relations to Chemistry, Geology, Mechanics, Physical Geology and Meteorology, Botany and Zoology, including Farm Architecture and Engineering, the valuation and management of Landed Property, with special reference to Canada.

Pupils may enter and leave the Class without being subjected to an examination. But with a view of promoting Emulation the Board of Agriculture offer the following Prizes, the value to be given in suitable books:—First, \$20 to the Student who shall pass the best Examination in all the subjects at the end of the term; Second, \$15; Third, \$10; and Fourth, \$5.

Further particulars may be known by applying either personally or by letter to Professor Buckland, University College.

Toronto, Nov., 1862.

## Horse Infirmary and Veterinary Establishment, Corner of Bay and Temperance Streets Toronto, C. W.

A SMITH, Licentiate of the Edinburgh Veterinary College, and Veterinary Surgeon to the Board of Agriculture of U. C., begs to return his thanks to the Public generally for their support since opening the above mentioned establishment, and respectfully solicits a continuance of the same.

And also begs to announce that Veterinary Medicines of every description are constantly kept on hand:—Such as, Physic, Diuretic, Cough Cordial, Tonic Condition, and Worm Balls and Powders. The constituents composing the Cough-balls, have been found (by Professor Dick, of Edinburgh) most serviceable in alleviating many of the symptoms of Brokenwind or Heaves in Horses. Colic Draughts, &c., a mixture which owners of Horses should always have beside them.

Liniments for Sore-throat, Sprain, Curb, Spavin, Ringbone.

Blistering Ointments. Liquid and sweating Blisters.

*Horses bought and sold on commission.*

Toronto, Aug. 30th, 1862.

## THOROUGH BRED STOCK FOR SALE.

THE SUBSCRIBER has for Sale Durham and Galloway Cattle, male and female.

Leicester, Cotswold, Lincolnshire, Down and Cheviot Sheep; Cumberland and Yorkshire improved Pigs. All imported stock.

GEORGE MILLER.
